• Some evidence suggests that repeated exposure to “hard” water may exacerbate condition.
• Family history of atopy
  – Asthma
  – Allergic rhinitis

COMMONLY ASSOCIATED CONDITIONS
• Food sensitivity/allergy in many cases; strong association with asthma and allergic rhinitis
• Association with both cutaneous and extra-cutaneous infections: URI, OM, UTI, cellulitis, erysipelas, zoster, endocarditis, MRSA, MSSA, pharyngitis, and rarely sepsis (1)
• Hyper-IgE syndrome (Job syndrome)
  – AD
  – Elevated IgE
  – Recurrent pyodermas
  – Decreased chemotaxis of mononuclear cells

DIAGNOSIS

HISTORY
• Presence of major symptoms, including relapsing of condition, family history, typical distribution, and morphology necessary to make diagnosis of AD
• Most prevalent symptoms: itch (54%), dryness and scaling (19.6%), inflamed skin (7.2%), skin pain (8.2%), sleep disturbance (11.4%) (3)

PHYSICAL EXAM
Primarily skin manifestations
• Distribution of lesions
  – Infants: trunk, face, and flexural surfaces; diaper-sparing
  – Children: antecubital and popliteal fossae
  – Adults: hands, feet, face, neck, upper chest, and genital areas
• Morphology of lesions
  – Infants: erythema and papules; may develop oozing, crusting vesicles
  – Children and adults: Lichenification and scaling are typical with chronic eczema as a result of persistent scratching and rubbing (lichenification rare in infants).
• Associated signs
  – Facial erythema, mild to moderate
  – Perioral pallor
  – Infraorbital fold (Dennie sign/Morgan line)—atopic pleat
  – Dry skin progressing to ichthyosis
  – Increased palmar linear markings
  – Pityriasis alba (hypopigmented asymptomatic areas on face and shoulders)
  – Keratosis pilaris
DIFFERENTIAL DIAGNOSIS
- Photosensitivity rashes
- Contact dermatitis (especially if only the face is involved)
- Scabies
- Seborrheic dermatitis (especially in infants)
- Psoriasis or lichen simplex chronicus if only localized disease is present in adults
- Rare conditions of infancy
  - Histiocytosis X
  - Wiskott–Aldrich syndrome
  - Ataxia-telangiectasia syndrome
- Ichthyosis vulgaris

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- No test is diagnostic.
- Serum IgE levels are elevated in as many as 80% of affected individuals, but test is not routinely ordered.
- Eosinophilia tends to correlate with disease severity.
- Scoring atopic dermatitis (SCORAD) is scoring system for AD comprising scores for area, intensity, and subjective symptoms.

TREATMENT

GENERAL MEASURES
- Minimize flare-ups and control the duration and intensity of flare-up.
- Avoid agents that may cause irritation (e.g., wool, perfumes).
- Minimize sweating.
- Lukewarm (not hot) bathing
- Minimize use of soap (superfatted soaps best).
- Sun exposure may be helpful.
- Humidify the house.
- Avoid excessive contact with water.
- Avoid lotions that contain alcohol.
- If very resistant to treatment, search for a coexisting contact dermatitis.

Pediatric Considerations
Chronic potent fluorinated corticosteroid use may cause striae, hypopigmentation, or atrophy, especially in children.

MEDICATION
Current recommendations discourage use of systemic treatments such as oral steroids, azathioprine, cyclosporin, etc.

First Line
- Frequent systemic lubrication with thick emollient creams (e.g., Eucerin, Vaseline) over moist skin is the mainstay of treatment before any other intervention is considered.
Infants and children: 0.5–1% topical hydrocortisone creams or ointments (use the “fingertip unit [FTU]” dosing)
Adults: higher potency topical corticosteroids in areas other than face and skin folds
Short-course, higher potency corticosteroids for flares; then, return to the lowest potency (creams preferred) that will control dermatitis.
Antihistamines for pruritus (e.g., hydroxyzine 10 to 25 mg at bedtime and as needed).

Second Line
Topical immunomodulators (tacrolimus or pimecrolimus) for episodic use for children >2 years. There is a black box warning from the FDA regarding potential cancer risk (no increased incidence noted over last 15 years of clinical use) (4).
Plastic occlusion in combination with topical medication to promote absorption.
For severe AD, consider systemic steroids for 1 to 2 weeks (e.g., prednisone 2 mg/kg/day PO [max 80 mg/day] initially, tapered over 7 to 14 days)—should be used very infrequently.
Topical tricyclic doxepin, as a 5% cream, may decrease pruritus.
Modified Goeckerman regimen (tar and ultraviolet light)
Low-dose methotrexate was established as effective treatment in adults, and recent review suggests it is safe for children and adolescents (5)[B].
Dupilumab, a biologic that targets mediators of inflammation (IL-22, IL-17, IFN-γ), has completed phase III trials and is awaiting approval.
Tezepelumab, a monoclonal antibody that targets thymic stromal lymphopoietin (a cytokine) recently gas been in trials that suggest a trend of being superior to topical corticosteroids (6).

ISSUES FOR REFERRAL
Ophthalmology evaluation for persistent vernal conjunctivitis
If using topical steroids around eyes for extended periods, ophthalmology follow-up for cataract evaluation

ADDITIONAL THERAPIES
Methods to reduce house mite allergens (micropore filters on heating, ventilation, and air-conditioning systems; impermeable mattress covers)
Behavioral relaxation therapy to reduce scratching
Bleach baths may reduce staph colonization, but definitive evidence for benefit in the condition is lacking. Recommend 1/2 cup of standard 6% household bleach for a full tub of water and soak for 5 to 10 minutes, blotting skin dry upon leaving the bath.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Evening primrose oil (includes high content of fatty acids)
– May decrease prostaglandin synthesis
– May promote conversion of linoleic acid to omega-6 fatty acid
Probiotics may reduce the severity of the condition, thus reducing medication use.
Evaluate to ensure that secondary bacterial or fungal infection does not develop as a result of disruption of the skin barrier. Most patients with AD are colonized by Staphylococcus. There is a little evidence for the routine use of antimicrobial interventions to reduce skin bacteria, but treatment of clinical infection with coverage for Staphylococcus is recommended.

**DIET**
- Trials of elimination may find certain “triggers” in some patients.
- Breastfeeding in conjunction with maternal hypoallergenic diets may decrease the severity in some infants (varying opinions).

**PATIENT EDUCATION**
- [http://www.aad.org/skin-conditions/dermatology-a-to-z/atopic-dermatitis](http://www.aad.org/skin-conditions/dermatology-a-to-z/atopic-dermatitis)
- National Eczema Association: [www.nationaleczema.org](http://www.nationaleczema.org)

**PROGNOSIS**
- Chronic disease
- Declines with increasing age
- 90% of pediatric patients have spontaneous resolution by puberty.
- Localized eczema (e.g., chronic hand or foot dermatitis, eyelid dermatitis, lichen simplex chronicus) may continue in some adults.

**COMPLICATIONS**
- Cataracts are more common in patients with AD.
- Skin infections (usually Staphylococcus aureus); sometimes subclinical
- Eczema herpeticum
  - Generalized vesiculopustular eruption caused by infection with herpes simplex or vaccinia virus
  - Causes acute illness requiring hospitalization
- Atrophy and/or striae if fluorinated corticosteroids are used on face or skin folds
- Systemic absorption may occur if large areas of skin are treated, particularly if high-potency medications and occlusion are combined.

**REFERENCES**

SEE ALSO

Algorithm: Rash

CODES

ICD10

L20.9 Atopic dermatitis, unspecified
L20.89 Other atopic dermatitis
L20.83 Infantile (acute) (chronic) eczema

CLINICAL PEARLS

- Institute early and proactive treatment to reduce inflammation. Use the lowest potency topical steroid that controls symptoms.
- Monitor for secondary bacterial infection.
- Frequent systemic lubrication with thick emollient creams (e.g., Eucerin, Vaseline) over moist skin is the mainstay of treatment before any other intervention is considered.
DERMATITIS, CONTACT
Anne Walsh, ANP-BC ● Konstantinos E. Deligiannidis, MD, MPH, FAAFP

BASICS
DESCRIPTION
- A cutaneous reaction to an external substance
- Each type has a different mechanism, whereas the clinical presentation is the same (1).
- Primary irritant dermatitis (ID) is a result of direct damage to the stratum corneum by chemicals or physical agents that occurs faster than the skin is able to repair itself, which results in an inflammatory nonimmunologic cutaneous reaction. Prior sensitization is not required (2). ID occurs immediately or within 48 hours of exposure (3).
- Allergic contact dermatitis (ACD) affects only individuals previously sensitized to a substance. It represents a delayed hypersensitivity reaction, requiring several hours or days for the cascade of cellular immunity to manifest itself (2,3).
- System(s) affected: skin/exocrine
- Synonym(s): dermatitis venenata

EPIDEMIOLOGY
Common

Incidence
Occupational contact dermatitis accounts for up to 70% of occupational skin disease occurrences and affects 20.5/100,000 workers per year in one Australian study.

Prevalence
- Florists, hairdressers, cooks, beauticians, and metal-working machine operators have the highest incidence (3).
- Predominant sex: male = female
  - Variations due to differences in exposure to offending agents as well as normal cutaneous variations between males and females (eccrine and sebaceous gland function and hair distribution)

Geriatric Considerations
Increased incidence of ID secondary to skin dryness

Pediatric Considerations
Increased incidence of positive patch testing due to better delayed hypersensitivity reactions (4)

ETIOLOGY AND PATHOPHYSIOLOGY
Hypersensitivity reaction to a substance generating cellular immunity response (5)
- Plants
  - Urushiol (allergen): poison ivy, poison oak, poison sumac
  - Primary contact: plant (roots/stems/leaves)
  - Secondary contact: clothes/fingernails (not blister fluid—the established eruption is not
itself contagious or transmissible)

- **Chemicals**
  - Nickel: jewelry, zippers, hooks, and watches (6)
  - Potassium dichromate: tanning agent in leather
  - Paraphenylenediamine: hair dyes, fur dyes, and industrial chemicals
  - Turpentine: cleaning agents, polishes, and waxes
  - Soaps and detergents

- **Topical medicines**
  - Neomycin: topical antibiotics
  - Thimerosal (Merthiolate): preservative in topical medications
  - Anesthetics: benzocaine
  - Parabens: preservative in topical medications
  - Formalin: cosmetics, shampoos, and nail enamel

**Genetics**
Increased frequency of ACD in families with allergies

**RISK FACTORS**
- Occupation
- Hobbies
- Travel
- Cosmetics
- Jewelry

**GENERAL PREVENTION**
- Avoid causative agents.
- Use of protective gloves (with cotton lining) may be helpful.

**DIAGNOSIS**

**HISTORY**
- Itchy rash
- Assess for prior exposure to irritating substance.

**PHYSICAL EXAM**
- **Acute**
  - Papules, vesicles, bullae with surrounding erythema
  - Crusting and oozing
  - Pruritus
- **Chronic**
  - Erythematous base
  - Thickening with lichenification
  - Scaling
  - Fissuring
- **Distribution**
  - Where epidermis is thinner (eyelids, genitalia)
  - Areas of contact with offending agent (e.g., nail polish)
– Palms and soles relatively more resistant, although hand dermatitis is common
– Deeper skin folds spared
– Linear arrays of lesions
– Lesions with sharp borders and sharp angles are pathognomonic.
– Well-demarcated area with a papulovesicular rash

DIFFERENTIAL DIAGNOSIS

- Based on clinical impression
  - Appearance, periodicity, and localization
- Groups of vesicles
  - Herpes simplex
- Diffuse bullous or vesicular lesions
  - Bullous pemphigoid
- Photodistribution
  - Phototoxic/allergic reaction to systemic allergen
- Eyelids
  - Seborrheic dermatitis
- Scaly eczematous lesions
  - Atopic dermatitis
  - Nummular eczema
  - Lichen simplex chronicus
  - Stasis dermatitis
  - Xerosis
- Id reaction (see separate chapter)

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other
Consider patch tests for suspected allergic trigger (systemic corticosteroids or recent, aggressive use of topical steroids may alter results).

Test Interpretation
- Intercellular edema
- Bullae

TREATMENT

GENERAL MEASURES

- Remove offending agent:
  - Avoidance
  - Work modification
  - Protective clothing
  - Barrier creams, especially high-lipid content moisturizing creams (e.g., Keri lotion, petrolatum, coconut oil)
- Topical soaks with cool tap water, Burow solution (1:40 dilution), saline (1 tsp/pt water), or silver nitrate solution
- Lukewarm water baths
- Aveeno oatmeal baths
- Emollients (white petrolatum, Eucerin)

**MEDICATION**

**First Line**

- **Topical medications (6)**
  - Lotion of zinc oxide, talc, menthol 0.15% (Gold Bond), phenol 0.5%
  - Corticosteroids for ACD as well as ID
    - High-potency steroids: fluocinonide (Lidex) 0.05% gel, cream, or ointment TID–QID
    - Use high-potency steroids only for a short time and then switch to low- or medium-potency steroid cream or ointment.
    - Caution regarding face/skin folds: Use lower potency steroids, and avoid prolonged usage. Switch to lower potency topical steroid once the acute phase is resolved.
- Calamine lotion for symptomatic relief
- Topical antibiotics for secondary infection (bacitracin, erythromycin)
- Systemic
  - Antihistamine
    - Hydroxyzine: 25 to 50 mg PO QID, especially useful for itching
    - Diphenhydramine: 25 to 50 mg PO QID
    - Cetirizine: 10 mg PO BID–TID
- Corticosteroids
  - Prednisone: Taper starting at 60 to 80 mg/day PO, over 10 to 14 days, occasionally 21 days.
  - Used for moderate to severe cases, particularly involving face or genitals
  - Little published evidence to compare appropriate length of treatment, but clinical experience suggests that short courses of therapy (i.e., 5 to 7 days) are not adequate to prevent rebound dermatitis.
  - Treatment for up to 21 days for severe/extensive rash resulting from exposure to potent allergens like urushiol (e.g., poison ivy) is commonly recommended to prevent reemergence of dermatitis upon taper (rebound), although 14 days is usually adequate.
  - May use burst dose of steroids for up to 5 days for less persistent immunogens or less severe dermatitis
- Antibiotics for secondary skin infections
  - Dicloxacillin: 250 to 500 mg PO QID for 7 to 10 days
  - Amoxicillin-clavulanate (Augmentin): 500 mg PO BID for 7 to 10 days
  - Erythromycin: 250 mg PO QID in penicillin-allergic patients
  - Trimethoprim-sulfamethoxazole (Bactrim DS): 160 mg/800 mg (1 tablet) PO BID for 7 to 10 days (suspected resistant Staphylococcus aureus)
- Precautions
  - Antihistamines may cause drowsiness.
  - Prolonged use of potent topical steroids may cause local skin effects (atrophy, stria, telangiectasia).
  - Use tapering dose of oral steroids if using >5 days.

**Second Line**

Other topical or systemic antibiotics, depending on organisms and sensitivity

**Pregnancy Considerations**
Usual caution with medications

**ISSUES FOR REFERRAL**
May need referral to a dermatologist or allergist if refractory to conventional treatment

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
The use of complementary and alternative treatment is a supplement and not an alternative to conventional treatment.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Rarely needs hospital admission

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Stay active, but avoid overheating.

**Patient Monitoring**
- As necessary for recurrence
- Patch testing for etiology after resolved

**DIET**
No special diet

**PATIENT EDUCATION**
- Avoidance of irritating substance
- Cleaning of secondary sources (nails, clothes)
- Fallacy of blister fluid spreading disease

**PROGNOSIS**
- Self-limited
- Benign
- 55% of patients still had contact dermatitis at 2 years after diagnosis (3).
- Improvement in rash less likely for those who remain in the same or similar profession (3)
- Increased length of exposure and atopy are poor prognostic indicators (3).

**COMPLICATIONS**
- Generalized eruption secondary to autosensitization
- Secondary bacterial infection

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: Rash

**CODES**

**ICD10**
- L25.9 Unspecified contact dermatitis, unspecified cause
- L23.9 Allergic contact dermatitis, unspecified cause
- L25.5 Unspecified contact dermatitis due to plants, except food

**CLINICAL PEARLS**
- Commonly occurs on hands and face
- Anyone exposed to irritants or allergic substances is predisposed to contact dermatitis, especially in occupations that have high exposure to chemicals.
- The most common allergens causing contact dermatitis are plants of the Toxicodendron genus (poison ivy, poison oak, poison sumac).
- Poison-ivy dermatitis typically requires 10 to 14 days (occasionally more) of topical or oral steroid therapy to prevent recurrent eruption.
- Worldwide, nickel is the number one patch-tested allergen causing ACD.
- The usual treatment for contact dermatitis is avoidance of the allergen or irritating substance and temporary use of topical steroids.
- A contact dermatitis eruption presents in a nondermatomal geographic fashion due to the skin being in contact with an external source.
DERMATITIS, DIAPER
Dennis E. Hughes, DO, FAAFP, FACEP

BASICS

DESCRIPTION
- Diaper dermatitis is a rash occurring under the covered area of a diaper (named for typical location, not etiology). It is usually initially a contact dermatitis but can be attributed to systemic condition.
- System(s) affected: skin/exocrine
- Synonym(s): diaper rash; nappy rash; napkin dermatitis

Geriatric Considerations
Incontinence is a significant cofactor in the elderly population.

EPIDEMIOLOGY

Incidence
- The most common dermatitis found in infancy
- Peak incidence: 7 to 12 months of age, then decreases
- Lower incidence reported in breastfed babies due to lower pH, urease, protease, and lipase activity.

Prevalence
Prevalence has been variably reported from 4–35% in the first 2 years of life. Upward of 75% of infants will have episodes of varying duration and severity in United States. Severity varies: 58% slight symptoms; 34% moderate; 8% severe. Under-reporting contributes to difficulty in determining impact of condition (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- Immature infant skin with histologic, biochemical, functional differences compared to mature skin (2)
- Wet skin is central in the development of diaper dermatitis, as prolonged contact with urine or feces results in susceptibility to chemical, enzymatic, and physical injury; wet skin is also penetrated more easily.
- Fecal proteases and lipases are irritants.
- Superhydrazase urease enzyme found in the stratum corneum liberates ammonia from cutaneous bacteria.
- Fecal lipase and protease activity is increased by acceleration of GI transit; thus, a higher incidence of irritant diaper dermatitis is observed in babies who have had diarrhea in the previous 48 hours.
- Once the skin is compromised, secondary infection by Candida albicans is common. 40–75% of diaper rashes that last >3 days are colonized with C. albicans.
- Bacteria may play a role in diaper dermatitis through reduction of fecal pH and resulting activation of enzymes.
- Allergy is exceedingly rare as a cause in infants.
RISK FACTORS
- Infrequent diaper changes
- Improper laundering (cloth diapers)
- Family history of dermatitis
- Hot, humid weather
- Recent treatment with oral antibiotics
- Diarrhea (>3 stools per day increases risk)
- Dye allergy
- Eczema may increase risk.

GENERAL PREVENTION
Most effectively managed by prevention including rigorous attention to hygiene

COMMONLY ASSOCIATED CONDITIONS
- Contact (allergic or irritant) dermatitis
- Seborrheic dermatitis
- Psoriasis
- Candidiasis
- Atopic dermatitis

DIAGNOSIS
Correct diagnosis is key. Ensure that no stigmata of systemic conditions exist (3).

HISTORY
- Onset, duration, and change in the nature of the rash
- Presence of rashes outside the diaper area
- Associated scratching or crying
- Contact with infants with a similar rash
- Recent illness, diarrhea, or antibiotic use
- Fever
- Pustular drainage
- Lymphangitis

PHYSICAL EXAM
- Mild forms consist of shiny erythema ± scale.
- Margins are not always evident.
- Moderate cases have areas of papules, vesicles, and small superficial erosions.
- It can progress to well-demarcated ulcerated nodules that measure ≥1 cm in diameter.
- It is found on the prominent parts of the buttocks, medial thighs, mons pubis, and scrotum.
- Skin folds are spared or involved last.
- Tidemark dermatitis refers to the bandlike form of erythema of irritated diaper margins.
- Diaper dermatitis can cause an id reaction (autoeczematous) outside the diaper area.

DIFFERENTIAL DIAGNOSIS
- Contact dermatitis
- Seborrheic dermatitis
Candidiasis
Atopic dermatitis
Scabies
Acrodermatitis enteropathica
Letterer-Siwe disease
Congenital syphilis
Child abuse
Streptococcal infection
Kawasaki disease
Biotin deficiency
Psoriasis
HIV infection

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Rarely needed

Follow-Up Tests & Special Considerations
- Consider a culture of lesions or a potassium hydroxide (KOH) preparation.
- The finding of anemia in association with hepatosplenicomegaly and the appropriate rash may suggest a diagnosis of Langerhans cell histiocytosis or congenital syphilis.
- Finding mites, ova, or feces on a mineral oil preparation of a burrow scraping can confirm the diagnosis of scabies.

Test Interpretation
- Biopsy is rare.
- Histology may reveal acute, subacute, or chronic spongiotic dermatitis.

TREATMENT

Prevention is the key to treatment of this condition.

GENERAL MEASURES
- Expose the buttocks to air as much as possible.
- Use mild, slightly acidic cleanser with water; no rubbing and pat dry.
- Avoid impermeable waterproof pants during treatment (day or night); they keep the skin wet and subject to rash or infection.
- Change diapers frequently, even at night, if the rash is extensive.
- Super-absorbable diapers are beneficial, as they wick urine away from skin and still allow air to permeate. Manufacturer-associated data indicates diapers with a mesh-like top sheet construction may be superior in allowing stool to separate from skin (4).
- Discontinue using baby lotion, powder, ointment, or baby oil (except zinc oxide).
- Use of appropriately formulated baby wipes (alcohol and fragrance-free) is safe and as effective as water.
- Apply zinc oxide ointment or other barrier cream to the rash at the earliest sign and BID or TID (e.g., Desitin or Balmex). Thereafter, apply to clean, thoroughly dried skin.
- Cornstarch can reduce friction. Talc powders that do not enhance the growth of yeast can
provide protection against frictional injury in diaper dermatitis, but do not form a continuous lipid barrier layer over the skin and obstruct the skin pores. These treatments are not recommended.

MEDIATION

First Line
- For a pure contact dermatitis, a low-potency topical steroid (hydrocortisone 0.5–1% TID for 3 to 5 days) and removal of the offending agent (urine, feces) should suffice.
- If candidiasis is suspected or diaper rash persists, use an antifungal such as miconazole nitrate 2% cream, miconazole powder, econazole (Spectazole), clotrimazole (Lotrimin), or ketoconazole (Nizoral) cream at each diaper change. Candida superinfection is common in persistent dermatitis in the moist diaper area.
- If inflammation is prominent, consider a very low-potency steroid cream such as hydrocortisone 0.5–1% TID along with an antifungal cream ± a combination product such as clioquinol–hydrocortisone (Vioform–Hydrocortisone) cream.
- If a secondary bacterial infection is suspected, use an antistaphylococcal oral antibiotic or mupirocin (Bactroban) ointment topically.
- Precautions: Avoid high- or moderate-potency steroids often found in combination of steroid antifungal mixtures—these should never be used in the diaper area.

Second Line
- Sucralfate paste for resistant cases
- Recent study suggests that use of hydrocolloid dressings can speed healing of rash.

ISSUES FOR REFERRAL
Consider if a systemic disease such as Langerhans cell histiocytosis, acrodermatitis enteropathica, or HIV infection is suspected.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization
  - Febrile neonates
  - Recalcitrant rash suggestive of immunodeficiency
  - Toxic-appearing infants
- Assist first-time parents with hygiene education.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Recheck weekly until clear, then at times of recurrence.

PATIENT EDUCATION
Patient education is vital to the treatment and prevention of recurrent cases.

PROGNOSIS
- Quick, complete clearing with appropriate treatment
- Secondary candidal infections may last a few weeks after treatment has begun.
COMPLICATIONS

- Secondary bacterial infection (Consider community-acquired methicillin-resistant Staphylococcus aureus [MRSA] in pustular dermatitis that does not respond to normal therapy.)
- Rare complication is inoculation with group A β-hemolytic Streptococcus resulting in necrotizing fasciitis.
- Secondary yeast infection

REFERENCES

SEE ALSO

Algorithm: Rash

CODES

ICD10

- L22 Diaper dermatitis
- B37.2 Candidiasis of skin and nail

CLINICAL PEARLS

- Hygiene is the main preventative measure.
- Look for secondary infection in persistent cases (candida, staph spp).
DERMATITIS, SEBORRHEIC
Blake Farber, MBBS • Naureen Rafiq, MBBS

BASICS

DESCRIPTION
Chronic, superficial, recurrent inflammatory skin disorder affecting sebum-rich, hairy regions of the body, especially the scalp, eyebrows, and face.

EPIDEMIOLOGY

Incidence
- Predominant age: infancy, adolescence, and adulthood
- Predominant sex: male > female

Prevalence
Seborrheic dermatitis: 3–5%

ETIOLOGY AND PATHOPHYSIOLOGY

- Skin surface yeast such as Malassezia may be a contributing factor (1).
- Genetic and environmental factors: Flares are common with stress/illness.
- Parallels increased sebaceous gland activity in infancy and adolescence or as a result of some acnegenic drugs.
- Seborrheic dermatitis is more common in immunosuppressed patients, suggesting that immune mechanisms are implicated in the pathogenesis of the disease, although the mechanisms are not well defined (1).

Genetics
Positive family history; no genetic markers have been identified to date.

RISK FACTORS
- Parkinson disease, epilepsy, traumatic brain and spinal cord injury, Down syndrome (1)
- Immunosuppressed conditions such as AIDS, lymphoma, organ transplantation (1)
- Emotional stress (1)
- Medications may cause flares/induce seborrheic dermatitis: buspirone, chlorpromazine, ethionamide, griseofulvin, haloperidol, interferon-α, methyldopa, psoralen, IL-2 (1)

GENERAL PREVENTION
Seborrheic skin should be washed more often than usual to soften the affected areas.

COMMONLY ASSOCIATED CONDITIONS
- Parkinson disease
- AIDS

DIAGNOSIS
Diagnosis of seborrheic dermatitis is usually made by history and physical exam. If unclear, a
punch biopsy of the skin will confirm the diagnosis.

**HISTORY**
- Intermittent active phases manifest with burning, scaling, and itching, alternating with inactive periods; activity is increased in winter and early spring, with remissions commonly occurring in summer.
- **Infants**
  - Cradle cap: greasy scaling of the scalp with occasional erythema
  - Diaper and/or axillary rash
  - Age of onset: ~1 month
  - Usually self-resolves by 8 to 12 months
- **Adults**
  - Red, greasy, scaling rash consisting of macules and plaques with indistinct margins.
  - Red, smooth, glazed appearance in skin folds
  - Minimal pruritus
  - Chronic waxing and waning course
  - Bilateral and symmetric
  - Most commonly located in hairy skin areas: scalp and scalp margins, eyebrows and eyelid margins, nasolabial folds, ears and retroauricular folds, presternal area, middle to upper back, buttock crease, inguinal area, genitals, and armpits

**PHYSICAL EXAM**
- Scalp appearance varies from mild, patchy scaling to widespread, thick, adherent crusts. Plaques are rare.
- Seborrheic dermatitis can spread onto the forehead, the posterior part of the neck, and the postauricular skin, as in psoriasis.
- Skin lesions manifest as brawny or yellow greasy scaling over red, inflamed skin.
- Hypopigmentation can be seen in African Americans.
- Infectious eczematoid dermatitis, with oozing and crusting, suggests secondary infection.
- Seborrheic blepharitis may occur independently.

**DIFFERENTIAL DIAGNOSIS**
- Atopic dermatitis: Distinction may be difficult in infants.
- Psoriasis
  - More common on the extensor surfaces of the knees, elbows and the nail beds are usually involved.
  - Scalp psoriasis will be more sharply demarcated than seborrheic dermatitis with crusted, infiltrated plaques rather than mild scaling and erythema.
- Candida
- Tinea cruris/capitis: Suspect these when usual medications fail or hair loss occurs.
- Eczema of auricle/otitis externa
- Rosacea
- Discoid lupus erythematosus: Skin biopsy will be beneficial.
- Histiocytosis X: may appear as seborrheic-like eruption
- Dandruff: scalp only, noninflammatory

**DIAGNOSTIC TESTS & INTERPRETATION**
Diagnostic Procedures/Other
Consider biopsy if:
- Usual therapies fail
- Petechiae are noted
- Histiocytosis X is suspected

Consider fungal cultures if:
- Refractory to treatment
- Pustules and alopecia are present

**Test Interpretation**

**Nonspecific changes**
- Hyperkeratosis, acanthosis, accentuated rete ridges, focal spongiosis, and parakeratosis are characteristic.
- Parakeratotic scale around hair follicles and mild superficial inflammatory lymphocytic infiltrate

**TREATMENT**

**GENERAL MEASURES**
- Increase frequency of shampooing.
- Sunlight in moderate doses may be helpful.
- Cradle cap
  - Frequent shampooing with a mild, nonmedicated shampoo
  - Remove thick scale by applying warm mineral oil and then wash off 1 hour later with a mild soap and a soft-bristle toothbrush or terrycloth washcloth.
- Adults: Wash all affected areas with antiseborrheic shampoos. Start with over-the-counter products (selenium sulfide), allowing shampoo/lotion to remain on the skin for several minutes before washing off, and increase to more potent preparations (containing coal tar, sulfur, or salicylic acid) if no improvement is noted.
- For dense scalp scaling, 10% liquor carbonic detergents in Nivea oil may be used at bedtime, covering the head with a shower cap. This should be done nightly for 1 to 3 weeks.

**MEDICATION**

**First Line**
- Cradle cap: Use a coal tar shampoo or ketoconazole (Nizoral) shampoo if the nonmedicated shampoo is ineffective. Massage in, and allow to remain on for several minutes before removing.
- Adults
  - Topical antifungal agents
    - Ketoconazole or miconazole 2% shampoo twice a week (allow to remain on scalp for several minutes before washing off) for clearance and then once a week or every other week for maintenance (1,2)[A]
    - Ketoconazole (Nizoral) and sertaconazole 2% cream may be used to clear scales in other areas (2)[A]
    - Ciclopirox 1% shampoo twice weekly (1,2,3)
    - Facial hair can also be treated with ketoconazole 2% shampoo (1)
  - Topical corticosteroids
Begin with 1% hydrocortisone and advance to more potent (fluorinated) steroid preparations daily for 2–4 weeks (Grade 2B) (1,3)[C]

- Avoid continuous use of potent steroids to reduce the risk of skin atrophy, hypopigmentation, and/or systemic absorption (especially in infants, children, and elderly).
- Precautions: Fluorinated corticosteroids and higher concentrations of hydrocortisone (e.g., 2.5%) may cause atrophy or striae if used on the face or on skin folds.
  - Other topical agents
    - Coal tar 1% shampoo twice a week
    - Selenium sulfide 2.5% shampoo twice a week
    - Zinc pyrithione 1% shampoo twice a week
    - Lithium gluconate/succinate 8% ointment/gel twice a week (4)
- Once controlled, washing with zinc soaps or selenium lotion with periodic use of steroid cream may help to maintain remission.

**Second Line**

- Calcineurin inhibitors
  - Pimecrolimus 1% cream BID (4)
  - Tacrolimus 0.1% ointment (4)
- Systemic antifungal therapy
  - Data is limited.
  - For moderate to severe seborrheic dermatitis
    - Ketoconazole: 200 mg/day (5)
    - Itraconazole: 200 mg/day (5)
    - Daily regimen for 1 to 2 months followed by twice-weekly dosing for chronic maintenance treatment
    - Monitor potential hepatotoxic effects.
- Low-molecular-weight hyaluronic acid
  - Hyaluronic acid sodium salt gel 0.2% BID

**ISSUES FOR REFERRAL**

No response to first-line therapy and concerns regarding systemic illness (e.g., HIV)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Every 2 to 12 weeks depending on the disease severity and the patient’s response to therapy

**PATIENT EDUCATION**

**PROGNOSIS**

- In infants, seborrheic dermatitis usually remits after 6 to 8 months.
- In adults, seborrheic dermatitis is usually chronic and unpredictable, with exacerbations and remissions. Disease is usually controlled with shampoos and topical steroids.
COMPLICATIONS
- Skin atrophy/striae are possible from fluorinated corticosteroids, especially if used on the face.
- Glaucoma and/or cataracts can result from use of fluorinated steroids around the eyes.
- Photosensitivity is caused occasionally by tars.
- Herpes keratitis is a rare complication of herpes simplex: Instruct patient to stop eyelid steroids if herpes simplex develops.

SEE ALSO
Algorithm: Rash

CODES

ICD10
- L21.9 Seborrheic dermatitis, unspecified
- L21.1 Seborrheic infantile dermatitis
- L21.0 Seborrhea capitis

CLINICAL PEARLS
- Search for an underlying systemic disease in a patient who is unresponsive to usual therapy.
In adults, seborrheic dermatitis is usually chronic and unpredictable, with exacerbations and remissions. Disease is usually easily controlled with shampoos and topical steroids.
DERMATITIS, STASIS
Joseph A. Florence, MD ● Fereshteh Gerayli, MD, FAAFP

BASICS

DESCRIPTION

- Chronic, eczematous, erythema, scaling, and noninflammatory edema of the lower extremities accompanied by cycle of scratching, excoriations, weeping, crusting, and inflammation in patients with chronic venous insufficiency (CVI), due to impaired circulation and other factors (nutritional edema)
- Clinical skin manifestation of CVI usually appears late in the disease.
- May present as a solitary lesion; can be associated with venous leg ulcer, which is located on the medial or lateral side of the ankle
- System(s) affected: skin/exocrine
- Synonym(s): gravitational eczema; varicose eczema; venous dermatitis

EPIDEMIOLOGY

Incidence

- In the United States: common in patients age >50 years (6–7%)
- Predominant age: adult, geriatric
- Predominant sex: female > male

Geriatric Considerations

Common in this age group:
- Estimated to affect 15 to 20 million patients age >50 years in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

- Incompetence of perforating veins, superficial venous thrombosis from varicose veins, and deep vein thrombosis (DVT) can each contribute to CVI leading to venous hypertension (HTN) and cutaneous inflammation. This can be a pathway to venous leg ulcer.
- Deposition of fibrin around capillaries
- Microvascular abnormalities
- Ischemia
- Continuous presence of edema in ankles, usually present because of venous valve incompetency (varicose veins)
- Weakness of venous walls in lower extremities
- Trauma to edematous, eczematized skin
- Itch may be caused by inflammatory mediators (from mast cells, monocytes, macrophages, or neutrophils) liberated in the microcirculation and endothelium.
- Abnormal leukocyte–endothelium interaction is proposed to be a major factor.
- A cascade of biochemical events leads to ulceration.

Genetics

Familial link probable

RISK FACTORS
- Atopy
- Chronic edema
- Old age
- Obesity
- Previous DVT
- Previous pregnancy
- Prolonged standing
- Secondary infection
- Superimposition of itch–scratch cycle
- Trauma
- Low-protein diet
- Genetic propensity
- Tight garments that constrict the thigh
- Vein stripping
- Vein harvesting for coronary artery bypass graft surgery
- Previous cellulitis

**GENERAL PREVENTION**
- Use compression stockings to avoid recurrence of edema and to mobilize the interstitial lymphatic fluid from the region of stasis dermatitis and also following DVT.
- Topical lubricants twice a day to prevent fissuring and itching

**COMMONLY ASSOCIATED CONDITIONS**
- Varicose veins
- Venous insufficiency
- Other eczematous disease
- Hyperhomocysteinemia
- Venous HTN

**DIAGNOSIS**

**HISTORY**
- Itching, pain, and burning may precede skin signs, which are aggravated during evening hours.
- Insidious onset
- Usually bilateral
- Description may include aching/heavy legs.
- Erythema, scaling, edema of lower extremities
- Noninflammatory edema preceded the skin eruption and ulceration.
- Edema initially develops around the ankle.

**PHYSICAL EXAM**
- Evaluation of the lower extremities characteristically reveals:
  - Bilateral scaly, eczematous patches, papules, and/or plaques
  - Violaceous (sometimes brown), erythematous lesions due to deoxygenation of venous blood (postinflammatory hyperpigmentation and hemosiderin deposition within the cutaneous tissue)
- Distribution: medial aspect of ankle, with frequent extension onto the foot and lower leg,
occasionally lateral side of ankle
- Brawny induration
- Stasis ulcers (frequently accompany stasis dermatitis) secondary to minor trauma
- Excoriations
- Weeping, crusting, inflammation of the skin
- Varicosities are often associated with ulcers.
- Clinical inspection reveals swelling and warmth.
- Skin changes are more common in the lower 1/3 of the extremity and medially.
- Early signs include prominent superficial veins and pitting ankle edema.
- May present as a solitary lesion mimicking a neoplasm

**DIFFERENTIAL DIAGNOSIS**
- Other eczematous diseases:
  - Atopic dermatitis
  - Uremic dermatitis
  - Contact dermatitis (due to topical agents used to self-treat)
  - Neurodermatitis
  - Arterial insufficiency
  - Sickle cell disease causing skin ulceration
  - Cellulitis
  - Erysipelas
- Tinea dermatophyte infection
- Pretibial myxedema
- Nummular eczema
- Lichen simplex chronicus
- Xerosis
- Asteatotic eczema
- Amyopathic dermatomyositis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
Duplex ultrasound imaging is helpful in diagnosis.

**Diagnostic Procedures/Other**
- Rule out arterial insufficiency. Check peripheral pulses; ankle brachial pressure index (ABPI or ABI)
- Check for diabetes.

**Test Interpretation**
- ABPI <0.8 is suggestive of arterial insufficiency.
- ABPI can be elevated, >1.2 in diabetic patients and others with distal small vessel calcifications.
- Arterial duplex ultrasound and angiography are the gold standards.

**TREATMENT**

**GENERAL MEASURES**
Primary role of treatment is to reverse effects of venous HTN. Appropriate health care:

- **Outpatient:**
  - Reduce edema:
    - Leg elevation: legs above the level of heart for 30 minutes, 3 to 4 times daily. Avoid prolonged dependent position.
    - Compression therapy: This is the mainstay of treatment of venous stasis ± ulcers. Compression bandages can be safely applied in patients with ABI of 0.8 to 1.2.
    - Elastic bandage wraps: Ace bandages or Unna paste boot (zinc gelatin) or compression stockings
      - Graduated elastic compression of 30 to 40 mm Hg at the ankle improves ulcer healing rate and may prevent ulcer recurrence (1)[A].
      - Compression bandages containing both elastic and inelastic components (mixed component systems) are as effective as four-layer bandages, are easier to apply, and have less slippage and associated with favorable quality of life outcomes.
      - High compression is contraindicated in arterial insufficiency.
      - Pneumatic compression devices are beneficial, especially in nonambulatory patients and those with a component of arterial insufficiency (2)[B].
  - Improvement of lipodermatosclerosis:
    - Activity:
      - Avoid standing still.
      - Stay active and exercise regularly.
      - Elevate foot of bed unless contraindicated.
  - Inpatient, for endovascular radiofrequency ablation, vein stripping, sclerotherapy, or skin grafts:
    - Venous ulcer treatment: Treat infection: Débride the ulcer base of necrotic tissue (surgical necrotomy if possible, or enzymatic débridement with collagenase).
      - Autolytic: Modern wound dressings (hydrogel, hydrocolloids, alginate, foam bandages, plain nonadherent dressing) are better than traditional wet to dry dressing because they maintain moist wound environment, with less tissue damage on removal, and less frequent changing requirement (2)[A]. However, there is no difference in healing rate of venous stasis ulcers by use of hydrocolloid dressing versus simple nonadherent dressing when used beneath compression.
      - Biologic: Topical application of granulocyte-macrophage colony-stimulating factor promotes healing of ulcers (insufficient evidence).
      - Mechanical: wet to dry dressings, hydrotherapy, and irrigation
      - Surgical: modifying cause of venous HTN (by venous ligation, valvuloplasty, and endoscopic perforator vein surgery); treat ulcer by graft.

**MEDICATION**

**First Line**

- Pentoxifylline 400 mg TID is effective in treating venous leg ulcer.
- The use of low-dose aspirin because adjuvant treatment for venous leg ulcers is not supported (3)[A].
- In light of increasing bacterial resistance to antibiotics, current guidelines recommend the use of antibacterial preparations only for clinical infection (cellulitis, increased pain, warmth, malodorous exudate), not for bacterial colonization (4)[A].
If secondary infection, treat with PO antibiotics for Staphylococcus or Streptococcus organisms (e.g., dicloxacillin 250 mg QID, cephalexin 500 mg BID, or levofloxacin 500 mg daily).

If MRSA suspected, clindamycin 300 mg QID, doxycycline 100 mg BID, TMP/SMX or IV vancomycin

There is no reliable evidence in the effectiveness of topical antiseptics such as povidone-iodine, peroxide-based preparations, mupirocin, chlorhexidine (4)[A].

Uncomplicated stasis dermatitis can be treated with short courses (about 2 weeks) of topical steroids (2)[B] (topical triamcinolone 0.1% cream/ointment BID).

Topical antipruritic: pramoxine, camphor, menthol, and doxepin

Topical anesthetic (lidocaine/prilocaine) may reduce pain during débridement.

Systemic steroids for severe cases

Silver sulfadiazine (SSD) has a positive effect in wound healing (2)[A].

**Second Line**

Consider antibiotics on basis of culture results of exudate from infected ulcer craters.

Lubricants when dermatitis is quiescent

Chronic stasis dermatitis can be treated with topical emollients (e.g., white petroleum, lanolin).

Antipruritic medications (e.g., diphenhydramine, cetirizine hydrochloride)

Hydrocolloid or a foam dressing may reduce ulcer pain; no evidence that ibuprofen dressings offer pain relief

**ISSUES FOR REFERRAL**

Consider referral for:

- Nonhealing ulcer
- Arterial insufficiency
- Uncertain diagnosis
- Rheumatoid arthritis
- Patch testing to evaluate for contact dermatitis
- Associated disease (e.g., symptomatic varicose veins)

**ADDITIONAL THERAPIES**

If the patient is on amlodipine, consider discontinuing.

**SURGERY/OTHER PROCEDURES**

Sclerotherapy and surgery may be required for associated disease.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- If Unna boot compression is used: Cut off and reapply boot once a week. Unna boots reduce edema by compression and prevent scratching.

**DIET**

Lose weight, if overweight.
PATIENT EDUCATION

- Encourage staying active to keep circulation and leg muscles in good condition. Walking is ideal.
- Keep legs elevated while sitting or lying.
- Do not wear girdles, garters, or pantyhose with tight elastic tops.
- Do not scratch.
- Avoid leg injury.
- Elevate foot of bed with 2- to 4-inch blocks.
- Apply compression stockings prior to getting out of bed when less edema is present. Regular use of high-compression stockings may prevent recurrence of venous ulcers.

PROGNOSIS

- Chronic course with intermittent exacerbations and remissions
- The healing process for ulceration is often prolonged and may take months.

COMPLICATIONS

- Sensations of itching, pain, and burning have negative impact on the quality of life.
- Secondary bacterial infection
- DVT
- Bleeding at dermatitis sites
- Squamous cell carcinoma in edges of long-standing stasis ulcers
- Scarring, which in turn leads to further compromise to blood flow and increased likelihood of minor trauma

REFERENCES

ADDITIONAL READING

- Partsch H, Flour M, Smith P; for International Compression Club. Indications for compression

SEE ALSO
- Varicose Veins
- Algorithm: Rash

CODES

ICD10
- I83.10 Varicose veins of unsp lower extremity with inflammation
- I83.11 Varicose veins of right lower extremity with inflammation
- I83.12 Varicose veins of left lower extremity with inflammation

CLINICAL PEARLS

- Treatment of edema associated with stasis dermatitis via elevation and/or compression stockings or bandages is essential for optimal results.
- Pentoxifylline may improve venous ulcer healing.
- No difference in healing rate of venous stasis ulcers by use of hydrocolloid dressing versus simple nonadherent dressing when used beneath compression. Decision about the dressing should be based on local cost and patient or physician’s preferences.
- Mild topical corticosteroids reduce inflammation and itching; however, these may potentiate infection; high-potency topical corticosteroids should be avoided due to increased risk of atrophy and ulceration.
DIABETES MELLITUS, TYPE 1
David T. Broome, MD ● Vicente T. San Martin, MD ● Betul A. Hatipoglu, MD

BASICS

DESCRIPTION
- Type 1 diabetes mellitus (T1DM) is a chronic disease caused by insulin deficiency following β-cell destruction.
- Results in hyperglycemia and potential end-organ complications.
- Features include:
  - Usually rapid onset
  - Absolute insulin dependence
  - Polyphagia, polydipsia, polyuria, and nocturia
  - Ketosis or diabetic ketoacidosis (DKA)
  - Body habitus: usually normal or thin physique at diagnosis
- System(s) affected: endocrine/metabolic, cardiovascular, neurologic, renal, ocular

Pregnancy Considerations
- T1DM confers maternal and fetal risk (spontaneous abortion, fetal anomalies, preeclampsia, fetal demise, macrosomia, neonatal hypoglycemia, and neonatal hyperbilirubinemia).
- Preconception counseling should address importance of glycemic control as close to normal as safely possible (goal A1c <6.5%) to reduce congenital anomalies.
- Glycemic targets during pregnancy: fasting <95 mg/dL, and either 1-hour postprandial <140 mg/dL, or 2-hour postprandial <120 mg/dL
- Dilated eye examinations should occur before pregnancy or in the 1st trimester and then patients should be monitored every trimester and 1-year postpartum (1)[B].
- HbA1c is slightly lower during pregnancy due to increased red blood cell turnover. The HbA1c target should ideally be <6% if achieved without hypoglycemia, but can be relaxed to <7% if necessary to prevent hypoglycemia (1)[B].
- Women with T1DM should be prescribed low-dose aspirin 60 to 150 mg/day (81 mg/day) until the baby is born (1).

EPIDEMIOLOGY
- Age of presentation is bimodal: at 4 to 6 years of age and at 10 to 14 years of age (early puberty) (2).
- No gender difference in overall incidence (3).

Incidence
- In the United States, incidence is 21.7/100,000 cases per year in patients aged 0–19 years (4).
- Substantially lower rates in other racial and ethnic groups.

Pediatric Considerations
In infants and toddlers, symptoms of T1DM may be subtle or masquerade as an intercurrent illness and thus are frequently misinterpreted or ignored.
Prevalence
The prevalence of type 1 diabetes of the entire U.S. ranges from 2.6/1,000 to 3.7/1,000 (5).

ETIOLOGY AND PATHOPHYSIOLOGY
- There are two main categories of T1DM: immune-mediated and idiopathic diabetes (1):
  - Immune-mediated diabetes: cellular-mediated autoimmune destruction of β cells of the pancreas (markers: autoantibodies to insulin, GAD65, tyrosine phosphatases IA-2 and IA-2β, including zinc transporter 8 autoantibody [ZnT8A]).
  - Idiopathic diabetes: no known etiology. Patients have permanent insulinopenia and are prone to ketoacidosis but have no evidence of autoimmunity.
- At least one autoantibody is present in 85–90% of individuals (1).

Genetics
- The disease has strong human leukocyte antigen (HLA) associations, with linkage to the DQA and DQB genes, and it is influenced by the DRB genes (HLA-DQA1, HLA-DQB1, and DLA-DRB1). These antibodies can be predisposing or protective (1).
- The major susceptibility locus maps to the HLA class II genes at 6p21 (accounting for 30–50% of genetic T1DM), but there are >40 loci (6).

RISK FACTORS
- HLA variations account for ~40% of the genetic risk for T1DM (6).
- Risk factors: viral infections, vitamin D deficiency, perinatal factors (maternal age, history of preeclampsia, neonatal jaundice), high birth weight for gestational age, and lower gestational age at birth.
- Increased susceptibility to T1DM is inheritable:
  - Only 15% of newly diagnosed patients have a positive family history of T1DM.
  - T1DM in monozygous twins with long-term follow-up is >50%.
  - Among first-degree relatives, siblings are at a higher risk (5–10% risk by age 20 years) than offspring.
  - Offspring of diabetic fathers are at a higher risk (~12%) than offspring of diabetic mothers (~6%) (6).

GENERAL PREVENTION
- Several studies have demonstrated that measuring islet cell autoantibodies may identify individuals at risk for T1DM (1).
- Although there is currently a lack of accepted screening programs, providers should consider referring relatives of those with type 1 diabetes for risk assessment in a clinical research study (www.diabetestrialnet.org) (1).
- Numerous clinical trials are currently being conducted to prevent type 1 diabetes (www.clinicaltrials.gov) (1).

COMMONLY ASSOCIATED CONDITIONS
- Autoimmune diseases, such as Addison disease, celiac disease, autoimmune hepatitis, pernicious anemia, myasthenia gravis, vitiligo, Graves disease and Hashimoto hypothyroidism.
- T1DM can also be seen as part of autoimmune polyendocrine syndromes.
DIAGNOSIS

HISTORY
- New-onset polyuria and polydipsia.
  - Polyuria may present as nocturia, bed-wetting, or incontinence in a previously continent child.
  - Polyuria may be difficult to appreciate in diaper-clad children.
- Silent (asymptomatic) incidental discovery

PHYSICAL EXAM
- Polyuria occurs when serum glucose concentration rises >180 mg/dL (10 mmol/L).
- Weight loss, increased fatigue, lethargy, muscle cramps
- Ketosis/DKA leads to abdominal discomfort, nausea.
- Vision changes, such as blurriness (6)

DIFFERENTIAL DIAGNOSIS
- Type 2 diabetes
- Monogenic diabetes considered when (1):
  - Diabetes diagnosed before 6 months of age should have immediate genetic testing.
  - Strong family history of diabetes without classic features of type 2 diabetes
  - Mild fasting hyperglycemia
  - Nonobese diabetic child with negative autoantibodies
- Secondary diabetes
  - Pancreatic disease (chronic pancreatitis, cystic fibrosis, hereditary hemochromatosis)
  - Endocrine-associated diabetes: acromegaly, Cushing syndrome, pheochromocytoma, glucagonoma, neuroendocrine tumors
  - Drug- or chemical-induced diabetes: glucocorticosteroids, HIV protease inhibitors, atypical antipsychotics, tacrolimus, cyclosporine, immune checkpoint inhibitors
- Acute poisonings (salicylate poisoning can mimic DKA)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Criteria for the diagnosis of diabetes:
  - Fasting (>8 hours) glucose ≥126 mg/dL (7.0 mmol/L) on more than one occasion
  - Random glucose of ≥200 mg/dL (11.1 mmol/L) in a patient with classic symptoms of hyperglycemia
  - Oral glucose tolerance test (OGTT): plasma glucose ≥200 mg/dL 2 hours after a glucose load of 1.75 g/kg (max dose 75 g)
  - Glycated hemoglobin (HbA1c) level ≥6.5%
- Other tests to consider:
  - Urinalysis for glucose, ketones, and albuminuria (urine albumin:creatinine ratio)
  - Pancreatic autoantibodies: Islet cell, IAA, GAD, IA2A, and ZnT8A
  - Serum β-hydroxybutyrate (BHB) and urine ketones
- C-peptide insulin level if needed to differentiate from type 2 diabetes because low or no C-peptide indicates insulinopenia

Follow-Up Tests & Special Considerations
Patients should be screened for celiac disease and thyroid disease on diagnosis (or soon thereafter) (1)[C].

Test Interpretation
In the absence of unequivocal hyperglycemia, results should be confirmed by repeat testing.

TREATMENT

GENERAL MEASURES
- Insulin is the mainstay of therapy.
- Education regarding matching of mealtime insulin dose to carbohydrate intake, premeal blood glucose level, and anticipated activity
  - Premeal blood glucose goal: 90 to 130 mg/dL (5.0 to 7.2 mmol/L).
  - Bedtime/overnight blood glucose levels goal: 90 to 150 mg/dL (5.0 to 8.3 mmol/L)
  - Pediatric A1c goal: <7.5% (A1c <7.0% is reasonable if achieved without excessive hypoglycemia)
  - Adult A1c goal: <7.0% (A1c <6.5% reasonable in select individuals); less stringent A1c goals (such as <8%) may be appropriate for elderly patients and other special populations

MEDICATION
- Most people with T1DM should be treated with multiple daily injections (MDI) of prandial insulin and basal insulin, or continuous subcutaneous insulin infusion (CSII).
- Most individuals with T1DM should use rapid-acting insulin analogs to reduce hypoglycemia risk.
- Types of injectable insulin:
  - Long-acting insulin analogs: insulin glargine, insulin detemir, and insulin degludec. These should not be mixed with other insulins in the same syringe.
  - Intermediate-acting insulin (NPH) can be mixed with other insulins.
  - Short-acting (regular) insulin
  - Rapid-acting insulin analogs: insulin lispro, insulin aspart, and insulin glulisine

First Line
- Flexible intensive insulin therapy is the gold standard.
- MDI or CSII have equal efficacy (1).
- Total initial dose is 0.2 to 0.4 units/kg/day for insulin-naive patients (up to 1.0 unit/kg/day in puberty).
- ~50% of total dose given as basal insulin, with the rest as bolus insulin.
- MDI regimen (1):
  - Basal, long-acting insulin once or twice a day
  - Prandial, short-acting insulin based on number of carbohydrate portions (e.g., 1:10, meaning 1 U of insulin for every 10 g of carbohydrates).
  - Correctional short-acting mealtime insulin based on premeal blood glucose level and sensitivity factor (e.g., 1 U for every 50 mg/dL over 150 mg/dL, where 50 mg/dL is the sensitivity factor)
- CSII regimen:
  - CSII and continuous glucose monitoring (CGM) should be encouraged when there is active patient/family participation (1).
Second Line
- Twice-daily injections with NPH along with regular or rapid-acting insulin (not physiologic, but lower cost and fewer injections).
- Pramlintide: delays gastric emptying, blunts pancreatic secretion of glucagon, and enhances satiety.
- Pancreatic and islet transplantation have been shown to normalize glucose levels but require lifelong immunosuppression; reserved for simultaneous renal transplantation, recurrent DKA, or severe hyperglycemia.

ISSUES FOR REFERRAL
New and established diagnoses of type 1 diabetes should be referred and managed by an endocrinologist.

ADDITIONAL THERAPIES
- Inhaled rapid acting insulin (may be used for mealtime coverage)
- Investigational agents (not yet FDA approved): metformin, GLP-1 receptor agonists, DPP-4 inhibitors, SGLT-1/SGLT-2 inhibitors (1)[C].

SURGERY/OTHER PROCEDURES
- All patients with type 1 diabetes should have basal insulin continued if not eating prior to a procedure.
- If patients are not eating on the morning prior to a procedure/surgery, prandial insulin should be held.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Complementary & alternative medicine has several investigations, but are not FDA approved to date.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Newly diagnosed patients with T1DM may require hospitalization during initiation of insulin therapy.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Regular aerobic exercise with care to avoid hypoglycemia:
- To reduce hypoglycemia, patients should lower basal requirements (temporary basal rate if using an insulin pump), or be advised to eat/drink 15–30 g of carbohydrates prior to vigorous exercise.
- Some patients may require both measures to reduce hypoglycemic events.

Patient Monitoring
- Blood pressure (BP) checks at every routine visit with a goal BP of <130/80 mm Hg
- Daily home blood glucose monitoring with home blood glucose meter: blood tests should be done at least 4–6 times/day.
- Comprehensive foot exam at least annually
- Quarterly measurement of HbA1c
For patients of all ages with diabetes and atherosclerotic cardiovascular disease (ASCVD), high-intensity statin therapy should be added to lifestyle therapy.

For patients with diabetes age 40 to 75 years and >75 years without ASCVD, use moderate-intensity statin in addition to lifestyle therapy.

Annual screenings:
- Albuminuria for earliest signs of possible nephropathy (urine albumin:creatinine ratio)
- Initial dilated comprehensive eye exam within 5 years of diagnosis and then annually
- Monofilament testing with pinprick, temperature, and vibration sensation for screening of peripheral neuropathy 5 years after diagnosis and then annually
- Annual influenza vaccine in patients ≥6 months of age
- Pneumococcal pneumonia with 13-valent pneumococcal conjugate vaccine (PCV13) is recommended before age 2. People aged 2 to 64 years should also receive a 23-valent pneumococcal polysaccharide vaccines (PPSV23). At age >65 years, regardless of vaccine history, PPSV23 is recommended.
- Hepatitis B vaccination to unvaccinated adults aged 19 to 59 years. Consider administering 3-dose series of hepatitis B vaccine to unvaccinated adults with diabetes ages ≥60 years.

**DIET**
- Carbohydrate counting using insulin-to-carbohydrate ratio with all meals and snacks allows patient flexibility in eating.

**PATIENT EDUCATION**
- Patient education of their diagnosis, carbohydrate counting, and nutritional recommendations are important.
- Yearly education with a certified diabetes educator should be considered to provide updates.
- Include smoking avoidance/cessation counseling as a routine component of diabetes care (1).

**PROGNOSIS**
- Initial remission or honeymoon phase with decreased insulin needs and easier control, usually 3 to 6 months
- Prognosis improves with careful blood glucose monitoring, improvement in insulin delivery regimens, and appropriate glycemic control.

**COMPlications**
- Microvascular disease (retinopathy, nephropathy, neuropathy)
- Hyperlipidemia
- Macrovascular disease (coronary and cerebral artery disease)
- Chronic foot ulcers/amputations
- Hypoglycemia
- DKA
- Excessive weight gain
- Increased risk for preeclampsia and preterm delivery
- Driving mishaps—recommend checking glucose before driving.
- Psychological problems of chronic disease

**REFERENCES**

CODES

ICD10
- E10.9 Type 1 diabetes mellitus without complications
- E10.8 Type 1 diabetes mellitus with unspecified complications
- E10.69 Type 1 diabetes mellitus with other specified complication

CLINICAL PEARLS

- The age of presentation of T1DM is bimodal: one peak at 4 to 6 years of age and a second peak at 10 to 14 years of age.
- At least one autoantibody is present in 85–90% of individuals when fasting hyperglycemia is initially detected.
- Therapy with MDI or CSII and the use of a multidisciplinary team care approach are associated with improved glycemic control, resulting in better long-term outcomes.
- Adult A1c goal is <7.0%; less stringent A1c goals may be appropriate for elderly patients and other special populations.
BASICS

DESCRIPTION
Diabetes mellitus (DM) type 2 is due to a progressive insulin secretory defect in the setting of insulin resistance.

Geriatric Considerations
Monitor elderly for hypoglycemia; adjust doses for renal/hepatic dysfunction and cognitive function; less aggressive glucose targets than in younger patients

Pediatric Considerations
Incidence is increasing and parallels obesity epidemic.

Pregnancy Considerations
Diet, metformin, glyburide, and insulin are all options for treatment of gestational diabetes.

EPIDEMIOLOGY
Incidence
1.5 million new cases in the United States each year

Prevalence
Estimated 30.3 million Americans (9.4% of the population); 90–95% are likely type 2.

ETIOLOGY AND PATHOPHYSIOLOGY
- Peripheral insulin resistance and/or defective insulin secretion with increased hepatic gluconeogenesis
- Genetic factors: usually polygenic; rarely monogenic (e.g., peroxisome proliferator-activated receptor [PPAR] γ and insulin gene mutations)
- Obesity (body mass index [BMI] ≥25 kg/m²) and visceral adiposity
- Gut microbiome changes
- Drug or chemical induced (e.g., glucocorticoids, highly active antiretroviral therapy [HAART], atypical antipsychotics, organ transplant immunosuppressants)

Genetics
- Genome-wide association studies show many common variants confer small causal effect; 50% concordance in monozygotic twins
- Family history is strongly predictive of risk.

RISK FACTORS
- Parental history of type 2 diabetes
- Gestational diabetes or history of baby with birth weight ≥4 kg (9 lb)
- Polycystic ovarian syndrome (PCOS)
- Hypertriglyceridemia or low high-density lipoprotein (HDL)—marker for insulin resistance
- Ethnicity: African American, Latino, Native American, Asian, and Pacific Islander
● Sedentary lifestyle, visceral obesity
● Use of thiazides, antipsychotics, glucocorticoids, and statins

GENERAL PREVENTION
● Maintenance of normal weight, or weight loss of 7% body weight, decrease intake of carbohydrates and overall calories. Moderate-intensity exercise and resistance training. Exercise 150 min/week.
● Use of metformin, α-glucosidase inhibitors, thiazolidinediones (TZDs), and glucagon-like peptide-1 receptor agonist (GLP-1 RA) in select patients with prediabetes (1)[B]

COMMONLY ASSOCIATED CONDITIONS
Hypertension, dyslipidemia, metabolic syndrome, fatty liver disease, infertility, PCOS, acanthosis nigricans, hemochromatosis

DIAGNOSIS

HISTORY
Polyuria, polydipsia, polyphagia, weight loss, weakness, fatigue, blurry vision, neuropathy, and frequent infections. Many individuals are asymptomatic.

PHYSICAL EXAM
BMI, waist circumference, fundoscopic exam, oral exam, cardiopulmonary exam, abdominal exam for hepatomegaly, focused neurologic exam, and diabetic foot exam

DIFFERENTIAL DIAGNOSIS
● Type 1 DM—low or absent insulin C-peptide, positive β-cell autoantibodies, ketosis
● DM is one of the features of Cushing syndrome, acromegaly, and glucagonoma.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Criteria for diagnosis (1)[A]
● HbA1c ≥6.5% or
● Hyperglycemic symptoms and random plasma glucose ≥200 mg/dL (11.1 mmol/L) or
● Fasting plasma glucose (FPG) ≥126 mg/dL (7.0 mmol/L) or
● 2-hour plasma glucose ≥200 mg/dL (11.1 mmol/L) during oral glucose tolerance test (OGTT) with 75-g glucose load
● If equivocal, repeat with a different test on the same sample or a repeat test in a separate sample.

Follow-Up Tests & Special Considerations
Screen patients with history of gestational diabetes for persistent diabetes/prediabetes with OGTT 6 to 12 weeks’ postpartum and every 3 years thereafter.

TREATMENT
Tight control of type 2 diabetes prevents long-term microvascular complications, but benefits on macrovascular outcomes are not as apparent. Individuals likely to benefit from a more aggressive
target (below) are those without preexisting DM complications, with recent diagnoses of DM, and with long life expectancy. Many medications have NOT been shown to improve long-term outcomes.

- Use patient-centered approach (individualized).
- Cornerstone of therapy is lifestyle modification, with diet and exercise and control of cardiovascular risk factors (particularly blood pressure [BP] and lipids).
- A1c targets—American Diabetes Association (ADA) recommendations (these are NOT universally accepted as not fully evidence based) (1)[C]. American College of Physicians targets differ (2).
  - A1c <7.0: for those with a long life expectancy, no cardiovascular disease (CVD), diagnosed DM for a short duration, and no history of hypoglycemia
  - A1c <8.0: for those with a limited life expectancy, advanced micro- or macrovascular complications, extensive comorbidities, and a history of severe hypoglycemia or long-standing DM in whom the general goal is difficult to attain
  - Many experts recognize more liberal targets (2).
  - ADA guidelines—preprandial glucose of 80 to 130 mg/dL and peak postprandial glucose of <180 mg/dL (1)[C]
- Use drugs from different classes for complementary action and limit side effects. Use monotherapy with metformin (if not contraindicated), but if A1c is ≥9%, start with dual therapy; if A1c ≥10%, BG 300 mg/dL, and patient is symptomatic, consider adding injectable therapy with insulin with/without GLP-1 analog (1)[A].
- Always consider side effect profile, CV benefit, and cost.

**GENERAL MEASURES**

- Diabetic foot exam at every visit
- Nephropathy: annual urine microalbumin-to-creatinine ratio and plasma creatinine (eGFR)
- Retinopathy: annual diabetic eye exam
- If 40 to 75 years old, begin a statin—moderate to high intensity based on atherosclerotic CVD (ASCVD) risk.
- If >50 years old, low-dose aspirin if at least one additional CV risk factor and low risk for GI bleeding
- Hypertension: goal BP <140/80 mm Hg (Tighter control may be considered on individual basis.)
- Pneumococcal (PPSV23) for all adults and pneumococcal conjugate vaccine (PCV13) for patients >65 years (and some younger—see CDC) and annual influenza vaccine

**MEDICATION**

**First Line**

**Monotherapy**

- **Metformin**
  - Reduces hepatic glucose production and has multiple other mechanisms of action
  - Preferred as first line due to high efficacy in lowering glucose, good safety profile, low risk of hypoglycemia, and low cost; also promotes weight loss
  - Some studies suggest CVD benefit; dosage: 500 to 2,000 mg in divided doses or extended release QD or BID (1)[A]
  - Avoid metformin in renal insufficiency with eGFR <30, prior to radiocontrast agent use, surgery, and severe acute illnesses (e.g., liver disease, cardiogenic shock, pancreatitis,
hypoxia) due to risk of lactic acidosis.
– Caution with acute heart failure, alcohol abuse, elderly; associated with GI side effects, vitamin $B_{12}$ deficiency (Monitor levels yearly.)
– Can be used in chronic kidney disease (CKD) patients with eGFR $\geq 45$; reduce dose to $\leq 1,000$ mg with close monitoring in patients with eGFR 30 to 45.
– About 10% of patients on metformin develop diarrhea. For these patients and other patients who have contraindications to metformin use, a different agent can be used as monotherapy.

**Second Line**

● General principles for choosing additional medications
  – If HbA1c not at goal, add second agent. Start with dual therapy when initial HbA1c $>9%$.
  – If patient has CAD, heart failure, or CKD, consider drugs shown to improve outcomes with these conditions.
  – Consideration should be given to drug-specific side effects (such as weight gain, hypoglycemia).
  – Cost of drug is an important consideration.
  – Choose regimen with patient input to optimize adherence (mode of administration, complexity).

● GLP-1 RA (incretins)
  – Stimulate glucose-dependent insulin secretion.
  – Promote weight loss, no risk of hypoglycemia; some improve CV outcomes.
  – Small risk of acute pancreatitis. Caution with use in CKD $\geq$ stage 4. May exacerbate gastroparesis. Most are injectable drugs, insulin dose may need reduction; relatively expensive
  – Should not be used in patients with personal history/family history of medullary thyroid cancer or multiple endocrine neoplasia (MEN) type 2 (black box warning)
  – Exenatide (Byetta): 5 to 10 $\mu$g SC BID within 60 minutes before meals and at least 6 hours apart or exenatide ER (Bydureon) 2 mg/week
  – Liraglutide (Victoza): 0.6 to 1.8 mg/day; reduced composite endpoint of cardiovascular death, nonfatal MI or nonfatal stroke; improved CV outcomes (3)
  – Dulaglutide (Trulicity): 0.75 to 1.50 mg weekly; improved CV outcomes (3)
  – Lixisenatide (Adlyxin): uptitration to 20 $\mu$g SC QD; available in combination (insulin glargine/lixisenatide) —15 to 60 U SC QD
  – Semaglutide (Ozempic): 0.25 to 1.00 mg weekly; improved CV outcomes (3); (Rybelsus) 3 mg to 14 mg orally daily

● SGLT2 inhibitors
  – Inhibit renal glucose reabsorption
  – Cause weight loss, no hypoglycemia risk
  – Canagliflozin, dapagliflozin, and empagliflozin reduced heart failure admissions and reduced progression of renal disease (3).
  – Empagliflozin and canagliflozin improved cardiovascular mortality outcomes (3).
  – Increase occurrence of genital mycotic infections and urinary tract infection. Increased risk of euglycemic diabetic ketoacidosis (DKA); relatively expensive
  – Do not initiate therapy if eGFR $<45$.
  – Canagliflozin (Invokana): 100 to 300 mg daily; increased risk for lower limb amputation
  – Dapagliflozin (Farxiga): 5 to 10 mg daily
  – Empagliflozin (Jardiance): 10 to 25 mg daily
- Ertugliflozin (Steglatro): 5–15 mg daily

**Dipeptidyl peptidase-4 (DPP-4) inhibitors**
- Inhibit the enzyme DPP-4, which deactivates endogenous incretins GLP-1 and GIP
- Minimal risk for hypoglycemia; reduce dose in renal impairment with exception of linagliptin.
- Weight neutral
- Alogliptin and saxagliptin are associated with heart failure, but sitagliptin is not.
- Clinical evidence shows no CV risk reduction (4).
- Sitagliptin (Januvia): 100 mg/day
- Saxagliptin (Onglyza): 2.5 or 5.0 mg daily
- Linagliptin (Tradjenta): 5 mg/day
- Alogliptin (Nesina): 25 mg/day

**Sulfonylureas**
- Stimulate pancreatic β-cell production of insulin
- Caution with renal or liver disease, sulfa allergy, creatinine clearance <50 mL/min
- May cause modest weight gain, hypoglycemia
- Low cost; widely available
- Glipizide (Glucotrol): 2.5 to 40.0 mg/day; dosage >10 mg/day given BID before meals
- Glipizide extended release: 5 to 20 mg/day
- Glyburide (DiaBeta, Glynase, Micronase): 1.25 to 20.00 mg/day, glynase: 0.75 to 12.00 mg/day
- Glimepiride (Amaryl): 1 to 8 mg/day

**TZD**
- Increases insulin sensitivity; activates PPARs to increase glucose utilization
- Pioglitazone reduces triglycerides (4); low cost
- Obtain baseline liver function tests (LFTs). Use with caution if history of heart failure, worsening of heart failure symptoms.
- Increased risk of fractures and low bone mass
- Pioglitazone (Actos): 15 to 45 mg/day
- Rosiglitazone (Avandia): 4 to 8 mg/day

**Insulin**
- Activates insulin receptors, increases glucose disposal, inhibits hepatic glucose production
- Potent glucose lowering effect; safe
- Consider as initial therapy in those with A1c >10%, catabolic symptoms, ketosis.
- Use as additional therapy if A1c not at goal after dual/triple therapy and GLP1-RA has been tried.
- Can cause weight gain. High hypoglycemia risk. High cost. NPH and regular insulin are more affordable, safe, and effective.
- Analogs have lower hypoglycemia risk than NPH and regular insulin.
- Neutral effects on CV outcomes
- Start with basal insulin at dose 0.1 to 0.3 U/kg/day. Titrate up to achieve desired blood glucose readings. Add mealtime (rapid/short acting) insulin if fasting glucose is at goal, but postmeal glucose is high. Mealtime starting dose can be 4 U or 10% of basal dose.
- Rapid-acting analogs—lispro (Humalog), aspart (Novolog), glulisine (Apidra): duration of action 3 to 5 hours; ultrarapid (Fiasp) quicker onset
- Inhaled insulin (Afrezza): rapid onset of action; duration of action 4.5 hours
– Short-acting insulin—human regular (Humulin R/Novolin R/ReliOn R): duration of action 6 to 8 hours
– Basal insulin analogs—glargine U-100 (Lantus, Basaglar): duration of action 22 to 24 hours; Glargine U-300 (Toujeo): duration of action 36 hours; detemir (Levemir): duration of action 21.5 hours. Degludec U-100, U-200 (Tresiba): duration of action 42 hours, does not need to be injected at same time each day
– Premixed insulin products—NPH/regular 70/30 (Novolin 70/30, Humulin 70/30), 70/30 and 50/50 aspart mix (Novolog mix), 75/25 and 50/50 lispro mix (Humalog mix)
– Mixed insulin must be taken with meals.
  ● Amylinomimetic
    – Delays gastric emptying, blunts pancreatic secretion of glucagon, and enhances satiety (1)
    – Causes weight loss and lower insulin doses
    – Pramlintide (Symlin): 60 to 120 μg SC premeal
    – Reduce prandial insulin by 50%.
  ● α-Glucosidase inhibitors
    – Inhibit intestinal α-glucosidase, slow intestinal carbohydrate digestions/absorption (1)
    – Avoid in renal insufficiency and bowel diseases.
    – Take at beginning of meals to decrease postprandial hyperglycemia.
    – Acarbose (Precose): 25 to 100 mg TID
    – Miglitol (Glyset): 25 to 100 mg TID
  ● Meglitinides
    – Mechanism similar to SU, but much shorter duration of action
    – Take at beginning of meals.
    – Repaglinide (Prandin): 0.5 to 4.0 mg TID
    – Nateglinide (Starlix): 60 to 120 mg TID
  ● Combination therapy
    – Drugs from different classes with complementary mechanisms of actions can be combined
    – Many formulations are available with combination of two oral medications, and injectable combinations of insulin with GLP-RA agonists

ADDITIONAL THERAPIES
  ● Bile acid sequestrants
    – Colesevelam: 3.75 g/day or 1.875 g BID
  ● Dopamine-2 agonists
    – Bromocriptine (Cycloset) 1.6 to 4.8 mg PO every AM; mechanism of action uncertain

SURGERY/OTHER PROCEDURES
For patients with BMI >35 kg/m², consider bariatric surgery (1)[A].

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
A1c twice a year for patients with well-controlled blood glucose and quarterly for patients with hyperglycemia or recent changes in therapy; periodic monitoring of lipids, renal functions, and urinary microalbumin

**PATIENT EDUCATION**
Diabetes self-management education

**PROGNOSIS**
Normal lifespan with prevention of complications

**COMPLICATIONS**
- Emergencies: hyperosmolar coma, DKA
- ASCVD, peripheral vascular disease, stroke, foot ulcers, Charcot joints
- Microvascular: peripheral neuropathy, proliferative retinopathy, erectile dysfunction, and diabetic CKD
- Ophthalmic: blindness, cataracts, glaucoma
- GI: nonalcoholic fatty liver disease, gastroparesis
- Neurologic: autonomic dysfunction, insensate feet

**REFERENCES**

**SEE ALSO**
- Diabetes Mellitus, Type 1; Diabetic Ketoacidosis; Hypertension, Essential
- Algorithm: Type 2 Diabetes, Treatment

**CODES**

**ICD10**
- E11.9 Type 2 diabetes mellitus without complications
- E11.319 Type 2 diabetes mellitus with unspecified diabetic retinopathy without macular edema
- E11.21 Type 2 diabetes mellitus with nephropathy

**CLINICAL PEARLS**
Individualize A1c targets based on life expectancy, preexisting DM complications, comorbidities, and individual patient preferences and values. Hypoglycemia poses more short-term danger than hyperglycemia. Exercise, diet, BP control, and CV risk reduction with statins are the cornerstones of DM treatment.
DIABETIC KETOACIDOSIS
Melanie J. Lippmann, MD

BASICS
DESCRIPTION
- A life-threatening medical emergency in diabetics secondary to insulin deficiency and characterized by hyperglycemia, ketosis, metabolic acidosis, electrolyte disturbances, and marked dehydration
- System(s) affected: endocrine/metabolic

EPIDEMIOLOGY
Incidence
- In the United States: 46 episodes per 10,000 diabetics; 2/100 patient-years of type 1 diabetes mellitus (DM) (1)
- Predominant age: 19 to 44 years (56%) and 45 to 65 years (24%); only 18% are <20 years.

ETIOLOGY AND PATHOPHYSIOLOGY
A deficiency of insulin, exacerbated by an increase in counterregulatory hormones (e.g., catecholamines, cortisol, glucagon, and growth hormone) leading to a hyperglycemic crisis, osmotic diuresis, ketosis with metabolic acidosis, and frequently accompanied by electrolyte disturbances
- Noncompliance/insufficient insulin: 25%
- Infection: 30–40%
- First presentation of DM: 10–25%
- Myocardial infarction (MI): 5–7%
- No cause identified: 10–30%
- Medications (corticosteroids, sympathomimetics, atypical antipsychotics)
- Illicit drugs (cocaine)
- Trauma
- Surgery
- Emotional stress
- Pregnancy
- Cerebrovascular accident (CVA)

RISK FACTORS
- Type 1 > type 2 DM
- Younger patients at higher risk

GENERAL PREVENTION
- Close monitoring of glucose during periods of stress, infection, illness, and trauma
- Careful insulin control and regular monitoring of blood glucose levels
- “Sick day” management instructions

COMMONLY ASSOCIATED CONDITIONS
Complications of chronic (and poorly controlled) DM such as nephropathy, neuropathy, and
retinopathy

DIAGNOSIS

HISTORY
- Recent illness, injury, or surgery
- Changes in diet or medications
- Missed insulin doses/noncompliance
- Insulin pump failure
- Weight loss in patients recently diagnosed with type 1 DM
- Polyuria, nocturia, polydipsia
- Hyperphagia
- Generalized weakness
- Malaise, fatigue, lethargy
- Anorexia or increased appetite
- Nausea, vomiting
- Abdominal pain
- Decreased perspiration
- Fever

PHYSICAL EXAM
- Hypotension
- Tachycardia
- Fever or hypothermia
- Tachypnea, hyperpnea, Kussmaul respirations
- Fruity odor of ketotic breath (acetone smell)
- Decreased reflexes
- Abdominal tenderness, decreased bowel sounds
- Dry mucous membranes, poor skin turgor, dehydration
- Altered mental status
- Coma

DIFFERENTIAL DIAGNOSIS
- Hyperosmolar hyperglycemic crisis
- Alcoholic ketoacidosis
- Starvation ketosis
- Toxic ingestions (e.g., salicylates, methanol)
- Lactic acidosis
- Uremia/chronic renal failure
- Sepsis
- Acute pancreatitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

ALERT
- Diagnostic criteria (1)[C]:

---

1. Diagnostic criteria (1)[C]:
- Hyperglycemia (glucose usually 250 to 800 mg/dL) as rapidly assessed on fingerstick glucose testing and confirmed on serum chemistry
- Low HCO$_3$ (usually ≤18 mEq/L)
- Metabolic acidosis on arterial blood gases (ABGs) (pH <7.3)
- Anion gap = serum sodium − (serum chloride + bicarbonate); >10 mmol

Other important labs:
- Serum ketosis: Check β-hydroxybutyrate (β-HB) instead of ketones to evaluate ketosis (2)[B]. β-HB is the predominant ketone produced and is preferred over serum ketones. β-HB >3 mg/dL is abnormal and should be decreased to <1.5 mg/dL within 12 to 24 hours (3)[B].
- Urine ketosis (urinalysis [UA]) may only identify acetoacetate and not β-HB.
- Increased creatinine and BUN: Markedly increased serum ketones may cross-react and cause a falsely high serum creatinine.
- Pseudohyponatremia: Hyperglycemia or hypertriglyceridemia may cause an artificially low sodium concentration. The measured sodium is suppressed by 1.6 mg/dL for every 100 mg/dL of glucose >100 mg/dL.
- Decreased calculated total body K$^+$: Severe acidosis gives an artificially high K$^+$ level.
- Increased serum osmolality (mOsm/kg) = [2 × serum Na (mEq/L) + glucose (mg/dL)/18 + BUN (mg/dL)/2.8]; if calculated osmolality <320 mOsm/kg, consider etiologies other than diabetic ketoacidosis (DKA).
- Elevated base deficit
- HbA1c (glycosylated hemoglobin) helps assess long-term history of diabetic control.
- Glycosuria
- Hyperamylasemia, hyperlipasemia
- Hypertriglyceridemia/hypercholesterolemia
- CBC, electrolytes, BUN, creatinine
- Serum β-HB or ketones
- ABG; venous blood gases (VBGs) may also be used (VBG pH correlates with 0.03 lower than ABG pH).
- Urine and blood cultures if concern for infection
- Troponin if concern for cardiac ischemia
- Other Tests
  - ECG
    - Frequently shows sinus tachycardia (nonspecific)
    - Changes consistent with electrolyte abnormalities
    - Ischemia/MI as a precipitating factor
  - Chest x-ray to rule out possible infectious etiology
  - Consider lumbar puncture if concern for meningitis.
  - Head CT scan if suspected CVA or cerebral edema

**DIAGNOSTIC PROCEDURES/OTHER**

Only if surgical disease is the underlying precipitant (e.g., appendicitis, cholecystitis)

**TREATMENT**

- Oxygen and airway management, as needed
- Establish IV access.
Cardiac monitoring
Start isotonic crystalloid solution (e.g., 0.9% saline, or lactated ringers bolus).

**GENERAL MEASURES**
- All, but mild cases require inpatient management.
- Severe DKA requires an ICU setting.
- Goals
  - Fluid resuscitation
  - Insulin therapy to normalize serum glucose
  - Resolution of anion gap acidosis and ketosis
  - Correction of electrolytes
- Identify and treat the precipitating cause (e.g., insulin noncompliance, infection, MI).
- Laboratory testing during management:
  - Serum glucose q1–2h until stable
  - Electrolytes, phosphorus, and venous pH q2–6h

**MEDICATION**

**First Line**
- **Insulin (1)[C]**
  - Optional initial bolus 0.1 U/kg IV and then continuous infusion at 0.1 U/kg/hr (do not use initial insulin bolus in children)
  - If without bolus, 0.14 U/kg/hr continuous infusion
  - Aim for rate of serum glucose decline of 100 mg/dL/hr
  - When glucose 200 mg/dL, reduce infusion to 0.02 to 0.05 U/kg/hr IV or give rapid-acting insulin at 0.1 U/kg SC q2h; goal glucose is 150 to 200 mg/dL.
  - Overlap and continue IV insulin infusion for 1 to 2 hours after SC insulin is initiated.
- IV fluids to correct dehydration: Start with 0.9% NaCl bolus, calculate corrected sodium; if serum Na\(^+\) is high, consider 0.45% NaCl to replace free fluid loss or when adding potassium replacement.
  - When glucose is 200 mg/dL, change to 5% dextrose with 0.45% NaCl at 150 to 250 mL/hr.
- Potassium: falsely elevated due to acidosis; when K\(^+\) ≤5.2 mg/dL and if urine output is adequate, start replacement with 20 to 30 mEq/L of K\(^+\) in 1 L IV fluids (1).
  - Hold insulin if K\(^+\) ≤3.3 mg/dL; give IV potassium 20 to 30 mEq/hr with fluids until >3.3 mg/dL to prevent cardiac arrhythmia (class III).
  - For each 0.1 unit of pH, serum K\(^+\) will change by ~0.6 mEq in opposite direction.
- Phosphorus: Routine replacement may lead to hypocalcemia; if very low (<1.0), give 20 to 30 mEq/L of K-Phos in fluids.
- Sodium bicarbonate: no demonstrable benefit with a pH >7.0 (2)[B]; rehydration usually leads to resolution of acidosis although some guidelines recommend its use with pH <6.9 or in patients with life-threatening hyperkalemia; however, there is evidence that it may increase cerebral edema, especially in children (3)[A].
- Magnesium: If Mg ≤1.8 mg/dL and the patient is symptomatic, consider replacement.
- Precautions
  - If the patient is on an insulin pump, it should be stopped.
  - If glucose does not fall by 10% in first hour, give regular insulin 0.14 U/kg IV bolus and then continuous infusion at previous rate.
– If using bicarbonate, add 100 mmol or 2 ampules of sodium bicarbonate to 400 mL isotonic solution with 20 mEq KCL >200 mL/hr for 2 hours until venous pH is >7.0 and then stop infusion (1).

**Second Line**

Insulin, SC or IM: Load with 0.3 U/kg SC, followed by 0.1 U/kg/hr; space dosing to q2h once glucose <250 mg/dL; in uncomplicated DKA, may be safe and cost-effective (4)[B]

**Pediatric Considerations**

- Children with moderate to severe DKA should be transferred to the nearest pediatric critical care hospital.
- Cerebral edema is a rare complication (~1%) but has a mortality of 20–50%
  - Diagnostic criteria exist for diagnosis; CT may rule out alternative diagnoses.
  - Treat with IV bolus of mannitol 1 g/kg in 20% solution, reduce IV fluid rate, and consider hypertonic 3% saline (5).

**Geriatric Considerations**

Must be careful with impaired renal function or congestive heart failure when correcting fluid and electrolyte abnormalities

**Pregnancy Considerations**

- Pregnancy itself is diabetogenic and also results in a compensated respiratory alkalosis (HCO₃⁻ 19 to 20 mEq/L) with theoretically reduced buffering capacity.
- Pregnant women are more susceptible to DKA.
- Euglycemic DKA
- Increased risk of preeclampsia and fetal death
- β-Tocolytics and corticosteroids can trigger DKA.
- Perinatal death: 9–35%

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- ADA admission guidelines: blood glucose >250 mg/dL; pH <7.3; HCO₃⁻ ≤15 mEq/L; ketones in urine; ICU setting for severe DKA (6)
- IV fluids
  - 1.0 to 1.5 L over the first hour, then, if serum corrected Na is high or normal, give 0.45% NaCl at 250 to 500 mL/hr depending on hydration state.
  - Switch to 5% dextrose in 0.45% saline at maintenance rate when serum glucose <200 mg/dL; maintain blood glucose between 150 and 250 mg/dL.
  - Overly rapid correction of fluid balance may precipitate cerebral edema (2)[C]; if the blood glucose level is falling too rapidly, consider using a 10% dextrose solution instead.

**Pediatric Considerations**

Bolus 10 to 20 mL/kg initially; 4-hour fluid total should be <50 mL/kg to reduce chance of cerebral edema.
- Discharge criteria
  - Discharge when DKA has resolved: anion gap <12, glucose <200 mg/dL; pH >7.3; bicarbonate >18 mEq/L; additionally, patients must be tolerating PO intake and able to resume home medication regimen
  - Underlying precipitant (e.g., infection) must be identified and treated.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Monitor mental status, vital signs, and urine output q30–60min until improved and then q2–4h.
- Monitor blood sugar q1h until <200 mg/dL and then q2–6h.
- Monitor electrolytes, BUN, venous pH, and creatinine q2–4h.

DIET
- NPO initially
- Advance to preketotic diet when nausea and vomiting are controlled.
- Avoid foods with high glycemic index (e.g., soft drinks, fruit juice, white bread, added sugar, etc.).

PROGNOSIS
- DKA accounts for 16% of all diabetes-related fatalities
- Overall DKA mortality of 0.5–2%
- In children <10 years of age, DKA causes 70% of diabetes-related fatalities.

COMPLICATIONS
- Cerebral edema (most common cause of death in children with DKA)
- Pulmonary edema
- Vascular thrombosis
- Hypokalemia
- Hypophosphatemia
- Cardiac dysrhythmia (secondary to hypokalemia or acidosis)
- MI, myocardial injury
- Acute gastric dilatation
- Late hypoglycemia (secondary to treatment)
- Erosive gastritis
- Infection, mucormycosis
- Respiratory distress

CODES

ICD10

- E10.10 Type 1 diabetes mellitus with ketoacidosis without coma
- E13.10 Oth diabetes mellitus with ketoacidosis without coma
- E10.11 Type 1 diabetes mellitus with ketoacidosis with coma

CLINICAL PEARLS

- Admit if blood glucose >250 mg/dL, pH <7.3, HCO3 ≤15 mEq/L, and ketones in urine.
- Potassium is falsely elevated due to acidosis; start replacement when K+ ≤5.2 mg/dL and urine output is adequate.
DIABETIC POLYNEUROPATHY
Samir Malkani, MD, MRCP–UK

BASICS

DESCRIPTION
Peripheral nerve dysfunction seen in diabetes; several patterns described:
- Symmetric polyneuropathy
  - Distal sensory or sensorimotor
- Mononeuropathy, radiculopathy, and polyradiculopathy
  - Cranial neuropathy
  - Focal limb or truncal neuropathy
  - Radiculoplexus neuropathy (diabetic amyotrophy)
- Acute painful small fiber neuropathy
- Autonomic neuropathies
- Chronic inflammatory demyelinating polyneuropathy (CIDP)

EPIDEMIOLOGY
Prevalence
- Generalized polyneuropathy
  - 10% at diabetes diagnosis
  - 50% at 10 years
  - Cross-sectional prevalence: 15% by symptoms; 50% by nerve conduction
- Autonomic neuropathy: 16.7% in a United Kingdom study

ETIOLOGY AND PATHOPHYSIOLOGY
- Metabolic derangement due to hyperglycemia
  - Aldose reductase converts excess glucose to sorbitol, which causes nerve damage.
  - Nonenzymatic glycation of neural proteins and lipids forms damaging advanced glycosylation end products.
  - Protein kinase C activation causes vascular endothelial changes.
  - Oxidative stress from excessive production of reactive oxygen species
  - Cyclooxygenase-2 and poly (ADP-ribose) polymerase activation
- Vasculopathy causing nerve ischemia: predominant factor in mononeuropathies

RISK FACTORS
- Poor glycemic control
- Duration of diabetes
- Hypertension
- Hyperlipidemia
- Tobacco and alcohol consumption

GENERAL PREVENTION
- Maintenance of normal blood sugar
- Exercise and appropriate diet
**DIAGNOSIS**

**HISTORY**

- Most common form (typical): symmetric distal sensory or sensorimotor polyneuropathy
  - Distressing numbness, tingling, pain of legs/feet, usually worse at night; allodynia; hyperalgesia
  - Often silent sensory loss, patient unaware
  - Ataxia due to proprioceptive loss
  - Neuropathic foot ulcers due to analgesia and repetitive injury
  - Neuropathic degeneration of foot joints
  - Hands involved late
  - Distal muscle involvement, usually mild

- Symmetric proximal polyneuropathy
  - Proximal leg weakness and wasting
  - Muscles of shoulder girdle rarely involved
  - Pain and sensory changes less prominent

- Focal cranial or limb mononeuropathy
  - May involve 3rd, 4th, 6th, or 7th cranial nerve
  - Femoral, sciatic, or peroneal neuropathy: weakness or pain in nerve distribution
  - Any major peripheral nerve can be involved.

- Truncal neuropathies: painful radiculopathy over dermatomes

- Lumbar radiculoplexus neuropathy (diabetic amyotrophy)
  - Unilateral hip, thigh pain
  - Pelvic girdle and thigh weakness with atrophy
  - Recovery over months

- Diabetic autonomic neuropathy
  - GI: nocturnal diarrhea, sometimes alternating with constipation; gastroparesis with postprandial fullness; nausea and vomiting
  - Cardiovascular: postural dizziness, exercise intolerance
  - Urogenital: urinary hesitancy, overflow incontinence; erectile dysfunction; vaginal dryness; sexual dysfunction
  - Sudomotor: anhidrosis or hyperhidrosis; gustatory sweating of head and upper body

- CIDP: progressive, severe motor loss

- Diabetic cachexia: painful small fiber neuropathy with prominent weight loss and depression

**PHYSICAL EXAM**

- Symmetric distal polyneuropathy
  - “Stocking-and-glove” distal sensory loss
  - Large-fiber neuropathy: loss of perception of vibration and light touch (10-g monofilament)
  - Small fiber involvement: loss of temperature and pinprick
  - Absent ankle reflexes
  - Wasting, weakness of small muscles in foot; changes to arch of foot or clawing of toes
  - With small fiber involvement, there may be lack of objective sensory deficit despite pain.

- Symmetric proximal polyneuropathy
  - Proximal leg, arm wasting, and weakness
  - Loss of patellar reflexes
• Focal cranial or limb mononeuropathy
  – 3rd cranial nerve palsy: painful ophthalmoplegia and ptosis; preserved pupillary reflexes (in contrast to compressive palsies)
  – 6th cranial nerve: lateral gaze palsy
  – Femoral neuropathy: weakness of lower leg extension, hip flexion, quadriceps wasting, absent patellar reflex, sensory loss in anterior thigh
  – Sciatic neuropathy: pain or sensory loss in back of thigh and leg; weakness of hamstrings, lower leg muscles
  – Peroneal neuropathy: foot drop
• Truncal neuropathies: sensory loss along dermatome
• Lumbar radiculoplexopathy (amyotrophy)
  – Weakness and wasting pelvic girdle and thigh
  – Sensory loss in L2–L3
  – Absent patellar reflex
• Autonomic neuropathy
  – Cardiovascular: resting tachycardia; orthostatic hypotension
  – Gastroparesis: postprandial distension; gastric splash
• CIDP: motor weakness

DIFFERENTIAL DIAGNOSIS
• Uremic polyneuropathy
• Drug induced
  – Antineoplastic drugs: cisplatin, vincristine
  – Isoniazid
  – Amiodarone
• Toxic
  – Chronic arsenic poisoning
  – n-Hexane, methyl-n-butyl ketone
• Nutritional deficiency
  – Usually associated with alcoholism
• Paraneoplastic polyneuropathy
• Hypothyroidism

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Fasting plasma glucose, 2-hour glucose tolerance test or hemoglobin A1c for diagnosis and to assess glycemic control; may occur in “prediabetes”
• Serum vitamin B₁₂
• Thyroid function
• Creatinine and BUN
• Syphilis testing
• Serum protein electrophoresis
• 25-OH Vitamin D
• In mononeuropathy/mononeuritis multiplex, test for vasculitis, paraproteinemia, and sarcoid.
• In radiculopathy or mononeuropathy, imaging studies to exclude compressive lesions

Diagnostic Procedures/Other
- Bedside testing of vibration perception with 128-Hz tuning fork, monofilament perception of 10-g filament, pinprick and temperature testing
- Quantitative sensory testing for vibratory and thermal thresholds
  - Standardized measures for assessing severity and risk of foot ulceration
- Electromyogram nerve conduction velocity
  - Useful to confirm mononeuropathy and entrapment syndromes
  - Sensitive but nonspecific index of presence and severity of diabetic polyneuropathy
  - In small unmyelinated fiber painful neuropathy, test may be normal.
- Lumbar puncture
  - In CIDP, elevation of spinal fluid protein
- Skin biopsy with epidermal nerve fiber density
  - Enables direct study of small nerve fibers that are difficult to assess electrophysiologically
- Corneal confocal microscopy
  - Noninvasive approach based on examination of corneal innervation

**Test Interpretation**
- In nerve biopsy of peripheral nerve, wallerian degeneration, focal axonal swellings containing neurofilaments, axonal atrophy, and demyelination are seen.
- Thick neural capillary basement membrane and endothelial proliferation
- Obliterative microvascular lesions and perivascular inflammation

**TREATMENT**

**GENERAL MEASURES**
- Maintain blood glucose close to normal.
- Provide appropriate footwear to prevent pressure damage to insensate feet.

**MEDICATION**
Specific treatment to reverse nerve damage, other than improved glucose control, is not available. Current therapies target pain relief.

**First Line**
Management of pain and sensory neuropathy
- Calcium channel modulators: gabapentin (1),(2,3)[A] (off-label)
  - Binds Ca$^{2+}$ channel–associated protein α$_2$-δ; inhibits neurotransmitter release
  - Dose range 300 to 1,200 mg TID, NNT ~4 to 8
  - Reduce dose in renal insufficiency.
  - Adverse effects: dizziness, fatigue, edema
- Calcium channel modulators: pregabalin (1,2,4)[A],(5)
  - Binds same calcium channel as gabapentin
  - Linear pharmacokinetics and quicker onset of action compared to gabapentin
  - Usual dose: 150 to 600 mg/day, NNT ~4 to 10
  - Adverse effects are dizziness and edema.
- Duloxetine (1,2),(5)[A]
  - Selective serotonin and norepinephrine reuptake inhibitor
  - Usual dose is 30 to 60 mg/day; NNT ~4 to 9
– Adverse effects are nausea and dizziness.

Tricyclic antidepressants (TCA) (1,2,5)[A] (off-label)
– Analgesia may be related to effects on sodium channels; NNT ~2 to 5, NNH ~3 to 16
– Amitriptyline 25 to 150 mg at bedtime
– Nortriptyline (25 to 150 mg); desipramine (25 to 200 mg) less sedating than amitriptyline but limited trial data
  o Anticholinergic effects and cardiac arrhythmias may occur.

Management of autonomic neuropathy
– Orthostatic hypotension
  o Fludrocortisone (off-label)
  o Midodrine (off-label)
– Gastroparesis
  o Metoclopramide or domperidone
  o Erythromycin (off-label)
– Diabetic diarrhea
  o Loperamide
  o Clonidine (off-label)
  o Octreotide (off-label)
  o Antibiotics for bacterial overgrowth
– Hyperhidrosis
  o Propantheline (off-label)

Geriatric Considerations
Anticholinergic effects of TCAs may cause urinary retention and cardiac arrhythmias.

Second Line
Antidepressants
– Venlafaxine (1,2,5)[A] (75 to 225 mg daily) (off-label), NNT ~2 to 5
  o Serotonin-norepinephrine reuptake inhibitor

Topical therapies
– Capsaicin (6) 0.075% cream applied TID
  o Depletes C fibers in skin of substance P
  o Limited data on efficacy
– Lidocaine (6) 5% (700 mg) patches applied daily to feet (off-label)
  o Causes sodium channel blockade

Opiate analgesia
– Tramadol (1,2) (off-label): 100 to 400 mg/day, NNT ~3 to 9
  o Binds opiate receptors; also inhibits reuptake of norepinephrine and serotonin; fewer opiate side effects
– Tapentadol (1,2)
  o Binds to μ-opiate receptor and inhibits norepinephrine uptake

ISSUES FOR REFERRAL
If CIDP is suspected, refer to neurologist for investigation and treatment.

ADDITIONAL THERAPIES
– Transcutaneous electrical nerve stimulation
– Percutaneous nerve stimulation
Electrical spinal cord stimulation
Actovegin, dextromethorphan with quinidine
C-peptide

SURGERY/OTHER PROCEDURES
Electrical spinal cord stimulation

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture, Reiki, electromagnetic field treatment: no convincing trial data

ONGOING CARE

PROGNOSIS
- Generalized symmetric polyneuropathies
  - Usually slow, chronic progression
  - Insensitive but painless foot as pain lessens
- Focal neuropathies
  - Recovery over months to years

COMPLICATIONS
- Claw foot deformity
- Neurotropic ulceration
  - Painless ulcers on weight-bearing area
  - Callus formation is a precursor to ulceration.
- Neuropathic arthropathy
  - Results in complete disorganization of joint structure in foot, Charcot joint

REFERENCES

ADDITIONAL READING

SEE ALSO
Diabetes Mellitus, Type 1; Diabetes Mellitus, Type 2

CODES

ICD10
- E10.42 Type 1 diabetes mellitus with diabetic polyneuropathy
- E11.42 Type 2 diabetes mellitus with diabetic polyneuropathy
- E13.42 Oth diabetes mellitus with diabetic polyneuropathy

CLINICAL PEARLS
- Occasionally, when glycemic control improves dramatically, as can occur when treatment for diabetes is initiated, there may be a worsening of neuropathy symptoms (described as treatment-induced neuropathy). Symptoms usually stabilize and gradually improve as glycemic control is maintained.
- It is common to combine agents with different mechanisms of action in the management of neuropathic pain. Topical therapies can be combined with systemic therapies. There is limited evidence-based data to support combination oral therapy, and maximizing the dose of a single agent may be more efficacious.
BASICS

DESCRIPTION
- An abnormal increase in stool water content, volume, or frequency (≥3 in 24 hours) for <14 days duration
  - Secondary to either impaired water absorption and/or active water secretion
- Most commonly secondary to infectious etiology; often self-limited
- If diarrhea persists or becomes chronic, consider non-infectious etiology.
- Acute viral diarrhea (50–70%)
  - Most common cause of infectious diarrhea; noninflammatory (watery)
  - Frequently presents with associated nausea and/or vomiting
  - Symptoms usually develop after an incubation period of ~1 day and last for 1 to 3 days; typically self-limited
- Bacterial diarrhea (15–20%)
  - Most common infectious cause of inflammatory (bloody) diarrhea
  - Incubation period variable; diarrhea caused by preformed enterotoxin presents within 1 to 6 hours of contaminated food ingestion, whereas bacterial infection typically presents within 1 to 3 days.
  - Symptoms usually resolve in 1 to 7 days; antibiotic use attenuates length and/or severity of disease.
  - Suspect when concurrent illness in others who have shared potentially contaminated food.
  - Suspect Clostridium difficile in patients with recent antibiotic use or hospitalization.
- Protozoal infections (10–15%)
  - Typically cause noninflammatory (watery) diarrhea
  - Long incubation period and prolonged disease course, symptoms develop approximately 7 days after exposure and commonly last >7 days
  - Suspect when outbreaks of watery diarrhea in areas with contaminated water or food supply.
- Traveler’s diarrhea (TD) typically begins 3 to 7 days after arrival in foreign location and resolves within 5 days; rapid onset, generally self-limited

EPIDEMIOLOGY
- In developing countries, acute diarrhea is more common in children; no age predilection in developed countries
- Acute diarrhea accounts for >128,000 U.S. hospital admissions and ~2.5 million annual deaths worldwide (1).

Prevalence
- Second leading cause of death in children <5 years and seventh leading cause of death among all ages worldwide
- Affects 11% of the general population
Rotavirus and adenovirus most common in children <2 years, bacteria are more common in children >2 years.

In developing world, acute diarrhea is largely due to contaminated food and water (1).

**ETIOLOGY AND PATHOPHYSIOLOGY**

- **Bacterial**
  - Escherichia coli
  - Salmonella, Shigella, Campylobacter jejuni
  - Vibrio parahaemolyticus, Vibrio cholerae
  - Yersinia enterocolitica
  - C. difficile
  - Staphylococcus aureus
  - Bacillus cereus
  - Clostridium perfringens
  - Listeria monocytogenes

- **Viral**
  - Rotavirus and Norovirus (most common)
  - Adenovirus
  - Astrovirus
  - Cytomegalovirus (in immunocompromised)

- **Protozoal**
  - Giardia lamblia
  - Entamoeba histolytica
  - Cryptosporidium
  - Isospora belli
  - Cyclospora, Microspora

- **Pathophysiology (1)**
  - Noninflammatory: most commonly viral. Increased intestinal secretions without disruption of intestinal mucosa; watery character
  - Inflammatory: generally invasive or toxin-producing bacteria; disrupts mucosal integrity with subsequent tissue invasion/damage; bloody character

- **Viral diarrhea**: changes in small intestine cell morphology, including villous shortening, increased number of crypt cells, and increased cellularity of the lamina propria

- **Bacterial diarrhea**: Bacterial invasion of colonic wall leads to mucosal hyperemia, edema, and leukocytic infiltration.

**RISK FACTORS**

- Travel to developing countries
- Failure to observe food/water precautions
- Immunocompromised host
- Antibiotic use
- Proton pump inhibitor (PPI) use
- Daycare exposure
- Fecal-oral sexual contact
- Nursing home residence
- Pregnancy (12-fold increase for listeriosis) (1)
GENERAL PREVENTION
- Frequent hand washing; reduces incidence of diarrhea by approximately 30%.
- Proper food and water precautions, particularly during foreign travel—“boil it, peel it, cook it, or forget it”
- Avoid undercooked meat, raw fish, unpasteurized milk.
- Rotavirus vaccine (for infants)
- Typhoid fever and cholera vaccine (for travel to endemic areas)
- TD Prevention:
  - Pretravel counseling on high-risk food/beverage
  o Consider daily prophylaxis with bismuth subsalicylate (BSS) in all travelers (can reduce the risk of TD by up to 60%); usual dosing of 2 tablets (262 mg each) or 2 oz (60 mL) liquid formulation 4 times daily
  o Do not use routine antibiotic prophylaxis
  o When indicated, the Infectious Disease Society of America recommends chemoprophylaxis with fluoroquinolones: norfloxacin 400 mg/day or ciprofloxacin 500 mg orally once or twice daily. Fluoroquinolones are not recommended for prophylaxis by the International Society of Travel Medicine, which advocates the use of rifaximin 200 mg once or twice daily (2)[C]
  o Probiotics, prebiotics, and synbiotics have unclear benefit as prophylaxis.

COMMONLY ASSOCIATED CONDITIONS
- Inflammatory bowel disease (IBD)
- Immunocompromised (HIV, malignancy, chemotherapy)

DIAGNOSIS

HISTORY
- Duration of symptoms <14 days
- Historical clues for dehydration: orthostatic hypotension, dizziness, increased thirst, decreased skin turgor, decreased and/or urine output, or altered mental status
- Description of stool—characteristics and output
  - Frequency; quantity; consistency; character: presence of mucus, blood, or fat; floating
  - Giardia associated with pale, greasy stools
- Weight loss
- Associated symptoms: change in appetite, abdominal pain or bloating, nausea/vomiting, or fever
- Recent hospitalization
- Antibiotic or PPI use
- Travel history
- Ingestion of raw or undercooked meat, raw seafood, unpasteurized milk
- Sick contacts
- Immunocompromised state
- Pregnancy
- Daycare exposure
- Sexual history (e.g., men who have sex with men [MSM], fecal-oral contact, HIV)
- Nursing home residence
- Cirrhosis (associated with Vibrio)
- Hemachromatosis (associated with Yersinia)

**PHYSICAL EXAM**
- Assess degree of dehydration (1); ill-appearing, dry mucous membranes, tachycardia, orthostatic hypotension, decreased skin turgor, delayed capillary refill, altered mental status; can be absent in early dehydration
- Fever is more suggestive of inflammatory diarrhea.
- Abdomen: Assess for distention, rigidity, rebound tenderness
- Rectum: blood, tenderness, stool consistency

**Geriatric Considerations**
Fecal impaction or obstructing neoplasm can cause overflow diarrhea with chronic constipation.

**DIFFERENTIAL DIAGNOSIS**
- IBD
- Malabsorption
- Medications (cholinergic agents, magnesium-containing antacids, chemotherapy, antibiotics)
- C. difficile colitis secondary to antibiotic use
- Diverticulitis, ischemic colitis
- Spastic (irritable) colon
- Fecal impaction
- Endocrinopathies: thyroid disease
- Neoplasia

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Reserve laboratory testing for patients with persistent fever, moderate-severe disease characterized by passage of ≥6 stools per day, duration of >72 hours, dysentery, profuse watery diarrhea, immunosuppression, or if suspected outbreak (3)[C].
- CBC
  - Leukocytosis, anemia (blood loss), eosinophilia (parasite infection), thrombocytopenia (hemolytic-uremic syndrome [HUS])
- Serum electrolytes
- BUN and creatinine may elevate with volume depletion.
- Nonanion gap metabolic acidosis
- Stool sample
  - Occult blood (IBD, bowel ischemia, and certain bacterial infections)
  - Fecal leukocytes
  - Stool ova and parasites
  - Stool culture: For bloody diarrhea, consider Salmonella, Shigella, Campylobacter, E. coli O157:H7, Y. enterocolitica, E. histolytica.
  - C. difficile toxin (especially IBD, recently hospitalized or recent antibiotic use) (4)[C]
  - Giardia ELISA >90% sensitive in at-risk population
  - Abdominal radiographs (flat plate and upright) if severe abdominal pain or concern for obstruction
  - Abdominal CT scan is preferred to evaluate intra-abdominal disease (5)[C].
**Diagnostic Procedures/Other**
- Consider sigmoidoscopy or colonoscopy in patients with persistent diarrhea, when there is no clear diagnosis after routine blood and stool tests, and if empiric or supportive therapy is ineffective.
- Consider colonoscopy in immunocompromised patients to evaluate for CMV colitis.
- Colonoscopy helps to distinguish infectious diarrhea from IBD, ischemic colitis, cancer, or other noninfectious etiologies (5)[C].

**TREATMENT**

**GENERAL MEASURES**
- Oral rehydration and electrolyte management are key to successful treatment.
- Oral intake, as tolerated—“if the gut works, use it”
- Balanced electrolyte rehydration solutions recommended in elderly and profuse, watery TD (3)[C]
- IV fluids if patient cannot tolerate oral rehydration or presents with severe dehydration

**MEDICATION**

**First Line**
- Consider empiric antibiotics (fluoroquinolones or macrolides) in patients with signs and symptoms of systemic infection, severe disease, or clear cases of TD (3)[C].
  - Fever; bloody diarrhea; fecal leukocytes
  - Immunocompromised host
  - Signs of severe volume depletion
  - Symptoms >1 week
- Tailor antibiotics to stool culture results (3)[C].
  - Giardia: metronidazole 250 mg PO TID for 5 to 7 days, tinidazole 2 g PO once
  - E. histolytica: metronidazole 500 to 750 mg PO TID for 7 to 10 days, tinidazole 2 g PO daily for 3 to 5 days
  - Shigella: ciprofloxacin 500 mg PO BID for 3 to 5 days or ceftriaxone 1 to 2 g IM/IV daily for 5 days
  - Campylobacter: azithromycin 500 mg PO daily for 3 to 5 days or erythromycin 500 mg PO QID for 5 days
  - C. difficile: vancomycin 125 to 500 mg PO QID for 10 to 14 days, or fidaxomicin 200 mg PO BID for 10 days; consider fecal microbiota transplant in recurrent mild to moderate C. difficile infections.
  - TD: ciprofloxacin 500 mg PO BID for 1 to 3 days, azithromycin (if suspicion of quinolone resistant pathogens) 500 mg PO daily or 1 g PO daily for 1 to 3 days, rifaximin 200 mg PO TID for 3 days; combined with loperamide 4 mg PO initial dose, followed by 2 mg after each episode of diarrhea for maximum of 8 mg daily; loperamide or BSS may be used alone in cases of mild TD (2)[C].
- General considerations
  - Antibiotics are not recommended in Salmonella infections unless caused by Salmonella typhosa or if the patient is febrile or immunocompromised.
  - Avoid antibiotics in patients with E. coli 0157:H7 due to risk for hemolytic uremic
syndrome (HUS).
– Antibiotics are not indicated for foodborne toxigenic diarrhea.
– Avoid antimotility agents (e.g., loperamide) in patients with febrile or bloody diarrhea (especially, E. coli 0157:H7) or antibiotic-associated colitis.
– Antimotility agents used in combination with antibiotics may speed recovery from TD.
– Antibiotics are not recommended for the treatment of mild TD (2)[C].
– C. difficile infections in IBD patients: Initially treat with vancomycin or fidaxomicin; consider fecal microbiota transplant in patients with recurrent C. difficile infections (4)[C].

● Significant medication interactions
  – Salicylate absorption from BSS can cause toxicity in patients already taking aspirin-containing compounds and may alter anticoagulation control in patients taking warfarin.
  – Avoid alcoholic beverages with metronidazole due to the possibility of a disulfiram reaction.

COMPLEMENTARY & ALTERNATIVE MEDICINE
● Bismuth subsalicylate may help control rate of diarrhea stools (3,6)[C].
● Probiotics are recommended for prevention of antibiotic-associated diarrhea and C. difficile infection recurrence and to treat acute infectious diarrhea in setting of symptomatic IBS (6)[C].
  Probiotic use >10^10/g may help in patients with antibiotic-associated diarrhea (2)[A].
  Probiotic strains Lactobacillus rhamnosus GG (LGG) and Saccharomyces boulardii most effective; may reduce duration by up to 1 day
  Avoid probiotics in immunocompromised patients (2)[A].
  Zinc supplementation can decrease diarrhea duration in children 6 months to 5 years of age who reside in countries with a high prevalence of zinc deficiency or who have signs of malnutrition.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Outpatient management, except for patients who are severely ill with signs of volume depletion

ONGOING CARE

DIET
● Early oral refeeding is encouraged. Regular diets are as effective as restricted diets.
● The traditional bananas, rice, applesauce, toast (BRAT) diet has little evidence-based support (despite heavy clinical use) and may result in suboptimal nutrition.
● During periods of active diarrhea, coffee, alcohol, dairy products, fruits, vegetables, red meats, and heavily seasoned foods may exacerbate symptoms.

PATIENT EDUCATION
See “General Prevention.”

PROGNOSIS
Acute diarrhea is rarely life-threatening if adequate hydration is maintained.

COMPLICATIONS
● Volume depletion, shock, sepsis
Anemia
- Hemolytic uremic syndrome with E. coli 0157:H7
- Guillain-Barré syndrome with C. jejuni
- Reactive arthritis with Salmonella, Shigella, and Yersinia
- Functional bowel disorders (e.g., postinfectious irritable bowel syndrome [PI-IBS])

REFERENCES

ADDITIONAL READING

SEE ALSO
- Botulism; Cholera; Food Poisoning, Bacterial

CODES
ICD10
- R19.7 Diarrhea, unspecified
- A09 Infectious gastroenteritis and colitis, unspecified
- A08.4 Viral intestinal infection, unspecified

CLINICAL PEARLS
Viruses are the most common causes of acute diarrheal illness in the United States.

Oral rehydration is the most important and effective treatment for acute diarrhea.

Routine stool culture is not recommended, unless patients present with bloody diarrhea, fever, severe dehydration, signs of inflammatory disease, persistent symptoms >7 days, or have a history of immunosuppression.

Start empiric antibiotics in patients who are severely ill or immunocompromised.
DIARRHEA, CHRONIC
Marie L. Borum, MD, EdD, MPH, MACP, FACP, AGAF • Ali A. Khan, MD, MPH

BASICS

DESCRIPTION
- An increase in frequency of defecation, urgency, or decrease in stool consistency (typically >3 loose stools per day) for >4 weeks (1)
  - Abnormal stool form is the most important defining factor; frequent defecation with normal consistency is termed pseudodiarrhea (1).
- Etiologies include osmotic, secretory, malabsorptive, inflammatory, infectious, and hypermotility.
- Infectious causes of chronic diarrhea are uncommon in immunocompetent patients. Parasitic etiologies are more common than bacterial.

EPIDEMIOLOGY

Incidence
Difficult to estimate as definitions may vary from patient to patient, though it has been estimated that the average American has an episode of diarrhea every other year

Prevalence
Varies by etiology; about 6.6% of the U.S. population (2) is affected.

ETIOLOGY AND PATHOPHYSIOLOGY

Chronic diarrhea is typically the result of disturbances in luminal water and electrolyte balance within the intestine that causes increased water volume in the stool.
- Osmotic (fecal osmotic gap >75 mOsm/kg) (1)
  - Carbohydrate malabsorption
    - Disaccharides, including lactose
    - Monosaccharides, including fructose
    - Polyols, including sorbitol, xylitol, sucralose, and saccharin (common sugar substitutes)—cannot be metabolized and create an osmotic gradient.
    - Magnesium, phosphate, and sulfate ingestion
- Secretory (fecal osmotic gap <50 mOsm/kg) (1,3)
  - Alcoholism
  - Bacterial enterotoxins (i.e., cholera)
  - Stimulant laxative ingestion
  - Postcholecystectomy
    - Excessive intestinal bile salts cause choleretic diarrhea; often resolves in 6 to 12 months
    - Ileal bile acid malabsorption
    - Ileal resection of <100 cm leads to choleretic diarrhea due to excessive colonic bile salts.
  - Disordered motility
    - Postvagotomy
    - Diabetic autonomic neuropathy
Hyperthyroidism
– Neuroendocrine tumors
  o VIPoma
  o Gastrinoma
  o Somatostatinoma
  o Carcinoid syndrome
– Metastatic medullary carcinoma of the thyroid
– Adrenal insufficiency
– Hyperthyroidism
– Noninvasive infection: giardiasis, cryptosporidiosis
– Microscopic colitis (lymphocytic or collagenous)
– Protein-losing enteropathy
– Idiopathic secretory diarrhea

Malabsorption (1,3)
– Celiac disease
– Whipple disease
– Tropical sprue
– Giardiasis
– Chronic mesenteric ischemia
– Lymphatic obstruction
– Short bowel syndrome: Ileal resection of >100 cm leads to insufficient bile salt concentrations in the duodenum for optimal fat absorption, leading to fat and fat-soluble vitamin malabsorption.
– Small intestinal bacterial overgrowth
– Pancreatic exocrine insufficiency (cystic fibrosis [CF], chronic pancreatitis)
– Inadequate bile acid production/secretion

Inflammatory (1,3)
– Ulcerative colitis; Crohn’s disease
– Microscopic colitis (lymphocytic or collagenous)
– Diverticulitis
– Vasculitis; radiation enterocolitis
– Eosinophilic enterocolitis
– Invasive or inflammatory infections: Clostridium difficile, Entamoeba histolytica, cytomegalovirus, tuberculosis
– Neoplasms: colon cancer, lymphoma, villous adenocarcinoma

Hypermotility (normal fecal osmotic gap) (1)
– Irritable bowel syndrome (IBS)
– Functional diarrhea

Drugs (1,3)
– Adverse effect of >700 drugs, most commonly: NSAIDs, PPIs, colchicine, metformin, digoxin, ACE inhibitors, β-blockers, newer gliptins, theophyllines, antibiotics, SSRIs, antineoplastic agents
– Factitious diarrhea: excessive laxative use

Herbal products: St. John’s wort, echinacea, garlic, saw palmetto, ginseng, cranberry extract, Aloe vera

Infectious (1)
– Bacterial: C. difficile, Mycobacterium avium intracellulare
– Viral: cytomegalovirus
– Parasitic: Giardia lamblia, Cryptosporidium, Isospora, E. histolytica
– Helminthic: Strongyloides
● Food allergies (1)

**Genetics**
● Celiac disease is associated with HLA-DQ2 and HLA-DQ8 haplotypes on major histocompatibility complex (MHC) class II antigen-presenting cells.
● Inflammatory bowel disease (IBD) is polygenic.
● CF is caused by a mutation in the CF transmembrane conductance regulator (CFTR), resulting in abnormal exocrine gland secretions.

**RISK FACTORS**
● Osmotic
  – Excess ingestion of nonabsorbable carbohydrates
  – Lactose intolerance
  – Celiac disease
● Secretory (1)
  – Postsurgical: extensive small bowel resection/ileal surgery, vagotomy, bile acid malabsorption
  – History of neuroendocrine disease
  – History of stimulant laxative abuse
  – Dysmotility syndromes
● Malabsorptive
  – CF
  – Chronic alcohol abuse
  – Chronic pancreatitis/pancreatic insufficiency
  – Celiac disease
  – Medications (i.e., orlistat, acarbose)
● Inflammatory
  – IBD
  – NSAID use
  – Thoracoabdominal radiation
  – HIV/AIDS
  – Antibiotic use
  – Immunosuppressant therapy
● Hypermotility
  – Psychosocial stress
  – Preceding infection
● Genetic predisposition

**ALERT**
Diabetes mellitus and/or prior cholecystectomy both cause secretory and osmotic diarrhea.

**GENERAL PREVENTION**
Varies by etiology; treat the underlying cause.
COMMONLY ASSOCIATED CONDITIONS

- Extraintestinal manifestations of IBD include arthralgias, aphthous stomatitis, uveitis/episcleritis, erythema nodosum, pyoderma gangrenosum, perianal fistulas, rectal fissures, ankylosing spondylitis, and primary sclerosing cholangitis.
- Celiac disease is associated with dermatitis herpetiformis, type 1 diabetes, other autoimmune disorders, and IgA deficiency.
- Many patients with IBS have behavioral comorbidities.
- Latex-food allergy syndrome: associated allergies to latex and banana, avocado, kiwi, and walnut (1)

DIAGNOSIS

HISTORY

- Detailed history of symptoms (1):
  - Onset, pattern, and frequency of stooling
  - Stool volume and quality (including presence of blood or mucus)
  - Travel history
  - Antibiotic exposure
  - Dietary patterns
  - Current medications
  - Family history (especially IBD or colorectal cancer)
- Determine aggravating or alleviating factors; changes with oral intake or improvement with selective food avoidance (i.e., dairy products)
- Alarm symptoms such as rectal bleeding/melena, unintentional weight loss, fevers, or nocturnal symptoms
- Skin changes (rashes, hives), arthritis, ocular problems, heat intolerance, polyuria/polydipsia, headache, fever, flushing, alcohol intake
- Food allergies are rare, occurring in only 1–2% of adults. Consider in patients with hives (1).
- Flatus and bloating are predominant features of carbohydrate malabsorption (1).
- Prior surgery or radiation therapy (3)
- History of systemic illness: endocrine, immunologic
- IBS or functional diarrhea by Rome IV criteria (3):
  - IBS: recurrent abdominal pain at least 1 day/week for past 3 months (symptoms >6 months); ≥2 of:
    - Related to defecation
    - Associated with change in frequency of stool
    - Associated with change in form of stool
  - Functional diarrhea: ≥25% loose or watery stools without prominent abdominal pain or bloating for >3 months (symptoms >6 months)

PHYSICAL EXAM

- General: volume depletion, nutritional status, recent weight loss (1)
- Skin: flushing (carcinoid), erythema nodosum (IBD), pyoderma gangrenosum (IBD), ecchymoses (vitamin K deficiency), dermatitis herpetiformis (celiac disease), hyperpigmentation (Addison disease) (1)
- HEENT: iritis/uveitis (IBD), lid lag (hyperthyroid)
Neck: goiter (hyperthyroid), lymphadenopathy (Whipple disease)
Cardiovascular: tachycardia (hyperthyroid), heart murmur (carcinoid syndrome) (3)
Pulmonary: wheezing (carcinoid)
Abdomen: hyperactive bowel sounds (IBD), abdominal distension (IBD/IBS), diffuse tenderness (IBD/IBS)
Anorectal: anorectal fistulas (IBD), anal fissures (IBD), fecal impaction (overflow incontinence)
Extremities: arthritis (IBD)
Neurologic: tremor (hyperthyroid)

DIFFERENTIAL DIAGNOSIS
See “Etiology and Pathophysiology,” “Commonly Associated Conditions,” and “Risk Factors.”

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Test patients with alarm symptoms or persistent symptoms and no identifiable cause.
- Blood: CBC, electrolytes (Mg, P, Ca), total protein, albumin, thyroid-stimulating hormone, free T₄, erythrocyte sedimentation rate, C-reactive protein, IgA anti-tissue transglutaminase (TTG), iron studies (1,2)
- Stool: WBCs or fecal calprotectin (preferred), culture, ova and parasites, Giardia stool antigen, C. difficile toxin, electrolytes, occult blood, osmololality, qualitative fecal fat (Sudan stain) (1)
  - Fecal osmotic gap = 290 mOsm/kg − 2(Na[feces] + K[feces])
- CT or MRI to evaluate the structure of the GI tract (i.e., IBD, malignancy, chronic pancreatitis) (1)

Follow-Up Tests & Special Considerations
- Celiac disease: antiendomysial antibody IgA, anti-TTG IgA, antigliadin (AGA) IgA, serum IgA (10% of celiac patients have IgA deficiency—may cause false-negative results)
- Chronic pancreatic insufficiency: fecal elastase and chymotrypsin (1)[C]
- Protein-losing enteropathy: fecal α₁-antitrypsin (1)[C]
- Microscopic colitis: mucosal biopsy from colon (3)[C]
- Carbohydrate malabsorption: fecal pH (<7.0) and hydrogen breath test
- Small bowel overgrowth: hydrogen breath test
- Recent hospitalization or antibiotics: C. difficile toxin
- HIV ELISA, Isospora/Cryptosporidium stains (1)[C]
- Consider testing for protozoa, atypical infections, Strongyloides, and tropical sprue in travelers and migrants of endemic areas (1)[C].
- Allergy testing (1)[C]
- Laxative abuse: stool osmolality, osmotic gap (3)[C]
- Neuroendocrine tumor (3)[C]
  - Serum: chromogranin A, VIP, gastrin, calcitonin
  - Urine: 5-HIAA, histamine

Diagnostic Procedures/Other
- Ileocolonoscopy with biopsies: IBD, microscopic colitis, CMV colitis, and colorectal neoplasia
- Flexible sigmoidoscopy: especially if pregnant, with comorbidities, or if left-sided symptoms predominate (tenesmus and urgency)
- Esophagogastroduodenoscopy (EGD) with small bowel biopsies if malabsorption is suspected:
  - Celiac, Giardia infection, Crohn disease, eosinophilic gastroenteropathy, Whipple disease, intestinal amyloid, pancreatic insufficiency
- Capsule endoscopy if further evaluation of small bowel is needed
- Upper GI series with small bowel follow-through
- CT or magnetic resonance (MR) enterography

**Test Interpretation**

- Celiac disease:
  - Marsh classification: intraepithelial lymphocytosis, crypt hyperplasia, villous atrophy
- Crohn disease: cobblestoning, linear ulcerations, skip lesions, noncaseating granulomas
- Ulcerative colitis: crypt abscesses, superficial inflammation
- Lymphocytic colitis: increased intraepithelial lymphocytes, increased inflammatory cells within the lamina propria, normal mucosal architecture
- Melanosis coli suggests laxative abuse.

**TREATMENT**

**GENERAL MEASURES**

- Volume resuscitation if necessary
- Electrolyte replacement as needed
- If stable, treatment is generally outpatient

**MEDICATION**

**First Line**

- Based on underlying cause:
  - Lactose intolerance: lactose-free diet
  - Post-cholecystectomy or ileal resection: cholestyramine or colestipol 2 to 16 g/day PO divided BID
  - Diabetes: glucose control
  - Hyperthyroidism: methimazole 5 to 20 mg/day PO, propylthiouracil (PTU) 100 to 150 mg/day PO divided; thyroid ablation
  - C. difficile: vancomycin 125 mg PO q6h or metronidazole (Flagyl) 500 mg PO q8h or fidaxomicin 200 mg PO BID
  - G. lamblia: metronidazole 250 mg PO q8h, nitazoxanide 500 mg PO q12h

- Whipple disease: ceftriaxone 2 g IV for 14 days then trimethoprim and sulfamethoxazole (Bactrim DS) 160/800 mg PO BID for 1 to 2 years
- Small intestinal bacterial overgrowth: rifaximin 550 mg PO BID, fluoroquinolones 250 to 750 mg PO BID, metronidazole 500 mg PO q6–8h, penicillins
- Pancreatic insufficiency: enzyme replacement
- HIV/AIDS: antiretroviral therapy
- Microscopic colitis: budesonide 9 mg/day PO, mesalamine 800 mg PO TID, Bismuth subsalicylate (Pepto-Bismol) 786 mg PO TID
- IBD: 5-aminosalicylic acid (5-ASA), corticosteroids (short-term only), antibiotics (short-term only), immunomodulators (6-mercaptopurine [6-MP], azathioprine, methotrexate), anti-TNF therapy (infliximab, adalimumab, certolizumab)
– Neuroendocrine tumor: octreotide 100 to 600 g/day SC (1)[C]

- Celiac disease: gluten-free diet (wheat/barley/rye avoidance)
- IBS diarrhea predominant: rifaximin 550 mg PO BID, alosetron 0.5 to 1.0 mg PO BID, peppermint oil, eluxadoline 100 mg PO BID (1)[C]

Symptom relief (1)[C]:
- Loperamide 4 to 8 mg/day PO divided
- Diphenoxylate-atropine 1 to 2 tabs PO BID–QID
- Fiber supplementation
- Bismuth subsalicylate 525 to 1,050 mg every 0.5 to 1 hour; max dose 4,200 mg/day (1)[C]

ISSUES FOR REFERRAL
Referral to a gastroenterologist for suspected inflammatory diarrhea

SURGERY/OTHER PROCEDURES
- Resection of neuroendocrine tumors
- Intestinal resection for medically refractory IBD
- Fecal transplant for recurrent C. difficile infection

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Consider inpatient hospitalization if patient is hemodynamically unstable, has severe electrolyte abnormalities or acute kidney injury, or is unable to tolerate oral intake.

ONGOING CARE

DIET
- Elimination diet: avoid gluten-containing foods, nonabsorbable carbohydrates, lactose-containing products, and food allergens depending on etiology of diarrhea.
- Low FODMAP (fermentable oligosaccharides, disaccharides, monosaccharides, and polyols) diet helps symptoms in up to 75% of IBS patients (1).
- High carbohydrate intake and obesity have been linked to chronic diarrhea (2).

PATIENT EDUCATION
- Diarrhea is generally defined as 3 or more loose bowel movements per day for over 4 weeks.
- Wide variation in “normal” bowel habits
- Restrict colon stimulants.
- Base specific education and dietary changes on underlying etiology.

PROGNOSIS
Varies according to etiology

COMPLICATIONS
- Fluid and electrolyte abnormalities, acute kidney injury
- Malnutrition, anemia, unintentional weight loss
- Malignancy (colon cancer in IBD, small bowel cancer in celiac disease and Crohn disease, lymphoma with IBD therapies)
- Infection with immunomodulator, biologic, and corticosteroid therapies for IBD
REFERENCES

SEE ALSO
Algorithm: Diarrhea, Chronic

CODES
ICD10
K52.9 Noninfective gastroenteritis and colitis, unspecified

CLINICAL PEARLS

- A comprehensive medical history guides the appropriate workup and avoids unnecessary testing.
- Consider IBS, IBD, malabsorption syndromes (i.e., lactose intolerance), celiac disease, over-the-counter medications, herbal products, and chronic infections (immunocompromised) in differential diagnosis.
- Laboratory tests should assess for malabsorption, electrolyte abnormalities, and acute kidney injuries. Imaging should rule out bowel obstruction, fistulae, or strictures.
- Treatment is based on the underlying cause.
INTERSTITIAL LUNG DISEASE
J. Andrew Woods, PharmD, BCPS ● Jacqueline L. Olin, MS, PharmD, BCPS, CDE, FASHP, FCCP ● Brice T. Taylor, MD

BASICS

DESCRIPTION
- Interstitial lung diseases (ILDs) represent a diverse group of chronic progressive lung diseases associated with alveolar inflammation and/or potentially irreversible pulmonary fibrosis.
- >200 individual diseases may present with similar characteristics, making ILD difficult to classify.
- A classification scheme proposed by the American Thoracic Society and European Respiratory Society includes these subtypes:
  - Known causes (environmental, occupational, or drug-associated disease)
  - Systemic disorders (e.g., sarcoidosis, Wegener granulomatosis, collagen vascular disease)
  - Rare lung diseases (e.g., pulmonary histiocytosis, lymphangioleiomyomatosis)
  - Idiopathic interstitial pneumonias (IIPs)
- Based on clinical, radiologic, and histologic features, IIPs are further subclassified into the following diagnoses (1):
  - Major IIPs, including idiopathic pulmonary fibrosis (IPF), nonspecific interstitial pneumonia (NSIP), respiratory bronchiolitis-associated ILD (cryptogenic organizing pneumonia [COP], etc.)
  - Rare IIPs
  - Unclassifiable IIPs
- IIPs and relationships between the subtypes are difficult to classify due to mixed patterns of injury.

Pediatric Considerations
ILD in infants and children represents a heterogeneous group of respiratory disorders. Diseases result from a variety of processes involving genetic factors and inflammatory or fibrotic responses, and processes are distinct from those that cause ILD in adults (2). Some diseases result from developmental disorders and growth abnormalities in infancy (2). After common causes are excluded, referral of infants to a subspecialist is recommended (2).

EPIDEMIOLOGY

Incidence
- Exact incidence and prevalence are difficult to determine because of differences in case definitions and procedures used in diagnosis.
- Cited incidence of IPF in the United States: 16.3 to 17.4/100,000 and pediatric ILD 1.32/1,000,000

Prevalence
Cited prevalence of IPF in the United States: 42.7 to 63 cases/100,000 in the general population and pediatric ILD of 3.6/1 million
ETIOLOGY AND PATHOPHYSIOLOGY

- Alveolar inflammation may progress into irreversible fibrosis.
- Varying degrees of ventilatory dysfunction occur among the ILD subtypes.
- ILD associated with collagen vascular disease and systemic connective disorders can manifest involvement of skin, joints, muscular, and ocular systems.
- Some types of ILD are associated with specific exposures:
  - Medications (amiodarone, antibiotics [especially nitrofurantoin], chemotherapy agents, gold, illicit drugs)
  - Inorganic dusts (silicates, asbestos, talc, mica, coal dust, graphite)
  - Organic dusts (moldy hay, inhalation of fungi, bacteria, animal proteins)
  - Metals (tin, aluminum, cobalt, iron, barium)
  - Gases, fumes, vapors, aerosols

Genetics
Some subtypes of ILD may be associated with specific predisposing genes and environmental exposures; however, the role of genetic factors is unknown.

RISK FACTORS
- Environmental or occupational exposure to inorganic or organic dusts
- 66–75% of patients with ILD have a history of smoking.
- Due to diversity of diseases, age is not a reliable predictor of pathology:
  - Most patients with connective tissue disease–related pathology and inherited subtypes present between ages 20 and 40 years
  - Median age of patients with IPF is 66 years. Studies of clinical predictors of survival including age, ethnicity, and smoking status have been inconsistent.

COMMONLY ASSOCIATED CONDITIONS
Many systemic disorders and primary diseases are associated with ILD. A partial list includes the following:
- Collagen vascular disease
- Sarcoidosis
- Amyloidosis
- Goodpasture syndrome
- Churg-Strauss syndrome
- Wegener granulomatosis

DIAGNOSIS
- Accurate diagnosis is imperative because treatment choices and prognosis can vary with pathogenesis.
- Diagnosis of IPF requires exclusion of other known ILD causes, the presence of a UIP pattern on high-resolution computed tomography (HRCT), and/or surgical lung biopsy pattern (3).

HISTORY
- Symptoms may include progressive exertional dyspnea and nonproductive cough.
- Patients may also present with hemoptysis or fatigue.
- Obtaining a history of illness duration (acute vs. chronic), potential
environmental/occupational exposures, travel, medical conditions (including systemic diseases), and medication reconciliation is important in assessing the cause of the ILD.

- Some cases of lung disease may occur weeks to years after discontinuation of an offending agent.

**PHYSICAL EXAM**
Physical findings are usually nonspecific. Some common features include the following:
- Fine crackles (typically present on auscultation of lung bases on posterior axillary line)
- Inspiratory “squeaks”
- Clubbing of the digits and cyanosis in advanced disease

**DIFFERENTIAL DIAGNOSIS**
- Acute pulmonary edema
- Diffuse hemorrhage
- Atypical pneumonia
- Diffuse bronchoalveolar cell carcinoma or lymphatic spread of tumor

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- O₂ saturation
- Peak expiratory flow rate
- CBC with differential, comprehensive metabolic profile
- CRP or erythrocyte sedimentation rate (ESR)
- Chest x-ray (CXR): most commonly reticular pattern, less commonly nodular or mixed patterns

**Follow-Up Tests & Special Considerations**
HRCT of the chest is the most useful tool for diagnosing then distinguishing among ILD subclasses, especially if normal CXRs:
- If indicated, arterial blood gas (ABG), hypersensitivity pneumonitis panel, plasma ACE inhibitor concentration (sarcoidosis)
- If a systemic disorder is suspected, consider antinuclear antibody (ANA), rheumatoid factor (RF), antineutrophil cytoplasmic antibodies (ANCA), anti-cyclic citrullinated (anti-CCP) peptide, and a myositis panel.

**Diagnostic Procedures/Other**
- Pulmonary function test (PFT; spirometry, lung volumes, carbon monoxide diffusing capacity)
  - Commonly demonstrates a restrictive defect (decreased vital capacity and total lung capacity)
  - Forced vital capacity (FVC) has been shown to decline 100 to 200 mL/year in the placebo arm of IPF patients in clinical trials.
- Bronchoscopy
  - Bronchoalveolar lavage (BAL) cellular analysis studies may be useful in distinguishing subtypes (including sarcoidosis, hypersensitivity pneumonitis, cancer). If performed, the BAL target site should be chosen based on the HRCT finding.
  - Bronchoscopic transbronchial lung biopsy may help diagnose sarcoidosis and, on occasion, is sufficiently supportive of other ILD diagnoses.
- Thoracoscopic surgery for lung biopsy has the greatest diagnostic specificity for ILDs but is
Less frequently used given that improved specificity of HRCT may be indicated if a diagnosis cannot be determined from transbronchial biopsy or HRCT.

**Test Interpretation**
- Diagnostic classifications of IIPs are based on histopathologic patterns seen on lung biopsy.
- Major histologies include an inflammation and fibrotic and granulomatous patterns.
- Characteristic changes on HRCT may help to distinguish between the following subtypes:
  - Reticulonodular, ground glass opacities, and, in later stages, honeycombing may be seen.
  - Associated hilar and mediastinal adenopathy are characteristic of stage I and II sarcoidosis.
- No specific test is the gold standard, which emphasizes the importance of a multidisciplinary consensus for diagnosis with clinical, radiologic, and pathologic findings.

**TREATMENT**
- Evidence does not support the routine use of any specific therapy for ILD in general, especially IPF (2,4).
- No survival benefit of home oxygen use in ILD
- Corticosteroids have a role in some ILD subtypes.
- Current evidence does not clearly support routine use of noncorticosteroid anti-inflammatory agents for IPF, including cyclosporine, colchicines, cyclophosphamide, cytokines, sildenafil, dual endothelin receptor antagonists (bosentan, macitentan), etanercept, methotrexate, or interferon.
- Clinical trials have indicated that anticoagulation (warfarin), ambrisentan, imatinib, and the combination of prednisone, azathioprine, and N-acetylcysteine are ineffective, potentially harmful, and therefore not recommended in the treatment of IPF (4)[A].
- Recombinant human thrombomodulin improved 3-month survival in the setting of acute exacerbation of IPF in a small historical control study.

**GENERAL MEASURES**
- Avoid/minimize offending environmental/occupational exposures/medications.
- Smoking cessation
- Supplemental oxygen, if indicated
- Annual influenza vaccination
- Pneumococcal vaccination, if indicated

**MEDICATION**

**First Line**
- Corticosteroids are most effective for certain ILDs, especially exacerbations of sarcoidosis, NSIP, COP, and hypersensitivity pneumonitis. However, response rates have been variable across and within subtypes. The optimal dose and duration of therapy are unknown.
  - Common starting dose of prednisone is 0.5 to 1.0 mg/kg/day for 4 to 12 weeks with potential up-titration based on patient response.
  - In patients with ILD associated with systemic sclerosis, nintedanib (Ofev), a tyrosine kinase inhibitor, reduced the rate of FVC decline versus placebo at 52 weeks (5).
- Two antifibrotic agents approved for IPF exhibited modest slowing of FVC decline over 52 weeks compared to placebo. Both decreased all-cause mortality rates. It is not clear if FVC is the most conclusive meaningful efficacy variable for IPF.
Pirfenidone (Esbriet) decreased the rate of decline in FVC compared to placebo. Secondary trial findings include a significant improvement in progression-free survival, and pooled analysis reveals a significant reduction in all-cause death and death from IPF (6). Pirfenidone has been shown to reduce respiratory-related hospitalizations in IPF (7). The most common adverse effects are GI related (nausea, vomiting, anorexia, weight loss, GERD, and dyspepsia), rash, insomnia, dizziness, fatigue, and aminotransferase elevation. Most AEs are mild to moderate in nature and do not result in pirfenidone discontinuation. Pirfenidone is not recommended for patients with severe liver impairment or ESRD (6)[A].

Pirfenidone is titrated over 2 weeks to 801 mg PO 3 times daily with food.

Nintedanib reduced the annual rate of decline in FVC, and fewer acute exacerbations occurred compared to placebo. The most common adverse effects are GI upset (nausea, vomiting, diarrhea, abdominal pain), anorexia, aminotransferase elevation, and hypertension. It is not recommended in moderate to severe liver impairment and can cause birth defects (8)[A].

Nintedanib is given at 150 mg PO twice daily with food.

Adding pirfenidone to nintedanib may convey a synergistic effect but could be limited by GI upset (9). Further investigation is warranted.

Second Line

- The addition of tacrolimus to corticosteroids (with cyclosporine, cyclophosphamide, or no additional therapy) may improve event-free survival in patients with ILD complicated with polymyositis or dermatomyositis.
- Several second-line agents have been used in Wegener granulomatosis:
  - Cyclophosphamide is commonly used in treatment of Wegener granulomatosis. It is given 1.5 to 2.0 mg/kg/day PO for 3 to 6 months.
  - Methotrexate has been used in treatment of mild Wegener granulomatosis in combination with corticosteroids. A studied dosing regimen consisted of an initial dose of 0.3 mg/kg (max dose of 15 mg) once weekly, with 2.5 mg titration each week (max dose of 25 mg/week).
  - Other second-line agents that have been studied include mycophenolate mofetil, and rituximab.

SURGERY/OTHER PROCEDURES

- Single- or double-lung transplantation may be a treatment of last resort. Lung transplant among selected IPF patients has demonstrated median survival of 4.5 years (8)[A]. Some ILDs associated with systemic disease may recur in the recipient lung.
- Alveolar type II cell intratracheal transplantation may benefit patients with moderate to progressive IPF.
- Clinical trials to assess the safety and efficacy of allogeneic human mesenchymal stem cell infusion in patients with mild to moderate IPF are ongoing.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Follow-up testing should include PFTs, 6-minute walk test, pulse oximetry, and CXR.
PATIENT EDUCATION
National Heart, Lung, and Blood Institute: http://www.nhlbi.nih.gov/health/health-topics/topics/ipf/

PROGNOSIS
IPF confers the worst prognosis (median survival of 2.5 to 3 years). A clinical prediction model to estimate the risk of death from ILD has been described (ILD-GAP model). Other subtypes, including hypersensitivity pneumonitis, NSIP, and COP, have a good prognosis.

COMPLICATIONS
- Cor pulmonale
- Pulmonary hypertension
- Pneumothorax
- Progressive respiratory failure

REFERENCES
CODES

ICD10
- J84.9 Interstitial pulmonary disease, unspecified
- J84.10 Pulmonary fibrosis, unspecified
- J84.111 Idiopathic interstitial pneumonia, not otherwise specified

CLINICAL PEARLS
- ILD differs from chronic obstructive pulmonary disease (COPD); anatomically, ILD involves the lung parenchyma (i.e., alveoli), and COPD involves both airways and alveoli.
- In some cases, avoiding or minimizing offending environmental/occupational exposures, medications, and smoking may alter disease severity.
DIVERTICULAR DISEASE
Andrew Harner, MD • Brianna Stadsvold, MD • Aaron Bolduc, MD

BASICS
DESCRIPTION
Diverticulum (single) or diverticula (multiple) are outpouchings of the colonic wall. Diverticular disease is a spectrum of diseases impacting the entire GI tract (except the rectum):
- Asymptomatic diverticulosis: common incidental finding on routine colonoscopy or imaging
- Symptomatic diverticulosis: also known as symptomatic uncomplicated diverticular disease (SUDD); recurrent abdominal pain attributed to diverticulosis without colitis or diverticulitis (1)
- Acute diverticulitis: diverticular disease with associated inflammation and/or infection
  - Uncomplicated diverticulitis: left lower quadrant (LLQ) pain, tenderness, leukocytosis but no peritoneal signs or systemic toxicity
  - Complicated diverticulitis: secondary abscess formation, bowel obstruction or perforation, peritonitis, fistula, or stricture
- Diverticular bleeding
  - Accounts for >40% of lower GI bleeds and 30% of cases of hematochezia in general
  - Bleeding more common with right-sided diverticula

EPIDEMIOLOGY
Incidence
- Diverticular disease accounts for ~300,000 hospitalizations per year in the United States.
- Diverticulitis occurs in 1–2% of the general population and in 4% of patients with diverticulosis over the course of their lifetime (1).
- Diverticular bleeding occurs in 3–5% of patients with diverticulosis.

Prevalence
- Prevalence of diverticulosis and the number of diverticula increase with age.
  - Diverticulosis occurs in 20% of those age 40 years, 60% of those age 60 years, and 70% by the age of 80 years.
  - Incidence of diverticulitis increased from 62 to 75/100,000 from 1998 to 2005; largest increase in patients <45 years of age—mostly due to changes in diet
- Male = female overall; more common in men <65 years of age and more common in women >65 years

ETIOLOGY AND PATHOPHYSIOLOGY
Diverticula form at points of weakness along the intestinal wall where small blood vessels (vasa recta) penetrate through the muscular layer of the colon.
- Age-related degeneration of the mucosal wall; increased intraluminal pressure from dense, fiber-depleted stools; and abnormal colonic motility contribute to diverticulosis.
- Most right-sided diverticula are true diverticula (involves all layers of the colonic wall).
- Most left-sided diverticula are pseudodiverticula (outpouchings of the mucosa and submucosa only).
- Diverticulitis occurs when local inflammation and infection contribute to tissue necrosis with
risk for mucosal micro- or macroperforation.

- Diverticulitis: Microscopy reveals inflammation with lymphocytic infiltrate, ulceration, mucin depletion, necrosis, Paneth cell metaplasia, and cryptitis.
- Alterations in intestinal microbiota contribute to chronic inflammation (1).
- Thinning of the vasa recta over the neck of the diverticula increases susceptibility to bleeding.
- Diverticular disease and irritable bowel syndrome (IBS) may represent the same disease continuum.

**Genetics**
- Though genetics may play a role, there is no known genetic pattern
- Asian and African populations have lower overall prevalence but develop diverticular disease with adoption of a Western lifestyle.

**RISK FACTORS**
- Age >40 years
- Low-fiber diet
- Sedentary lifestyle, obesity
- Previous diverticulitis. Risk rises with the number of diverticula.
- Smoking increases the risk of perforation (1).
- Risk of diverticular bleeding increases with NSAIDs, steroids, and opiate analgesics. Calcium channel blockers and statins protect against diverticular bleeding.

**GENERAL PREVENTION**
- High-fiber diet or nonabsorbable fiber (psyllium)
- Vigorous physical activity

**COMMONLY ASSOCIATED CONDITIONS**
Colon cancer, connective tissue diseases, obesity, and inflammatory bowel disease

**DIAGNOSIS**

**HISTORY**
- Diverticulosis
  - 80–85% of patients are asymptomatic. Of the 15–20% with symptoms, 1–2% will require hospitalization, and 0.5% will undergo surgery.
  - The most common symptom is dull, colicky abdominal pain, typically in the LLQ. Pain can be exacerbated by eating and by passing bowel movement or flatus.
  - Diarrhea or constipation is common.
- Acute diverticulitis: uncomplicated (85%) and complicated (15%)
  - Abdominal pain: acute onset, typically in LLQ
  - Fever and/or chills
  - Anorexia, nausea (20–62%), or vomiting
  - Constipation (50%) or diarrhea (25–35%)
  - Dysuria and urinary frequency suggest bladder or ureteral irritation.
  - Pneumaturia and fecaluria with colovesical fistula
- Diverticular bleeding
  - Melena, hematochezia (0.5/1,000 person-years)
Painless rectal bleeding

Immunocompromised patients may not present with fever or leukocytosis and are at higher risk for perforation and abscess formation.

PHYSICAL EXAM

Diverticulosis
- Exam is usually normal.
- May have intermittent distension or tympany
- May have heme + stools

Acute diverticulitis
- Abdominal tenderness (usually LLQ)
- Abdominal distension and tympany
- Rebound tenderness, involuntary guarding, or rigidity suggests perforation and/or peritonitis.
- Palpable mass in LLQ (20%)
- Bowel sounds hypoactive (could be high-pitched and intermittent if obstruction is present)
- Rectal exam may reveal tenderness or a mass.
- Colovaginal, colovesical, and perirectal fistulae are rarely the initial presentation.

DIFFERENTIAL DIAGNOSIS
Urinary tract infection, nephrolithiasis, IBS, lactose intolerance, carcinoma, inflammatory bowel disease, fecal impaction, bowel obstruction, angiodysplasia, ischemic colitis, acute appendicitis, ectopic pregnancy

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Diverticulosis: no labs or imaging needed
Acute diverticulitis
- WBC count is normal in up to 45% of cases. As diverticulitis worsens, WBC count becomes elevated with left shift.
- Hemoglobin normal (unless bleeding)
- ESR elevated
- Urinalysis may show microscopic pyuria or hematuria
- Urine culture: usually normal; persistent infection is suspicious for colovesical fistula.
- Blood cultures positive in systemic cases
- Plain films of the abdomen (acute abdominal series—supine and upright) to assess for free air under the diaphragm (bowel perforation) and signs of bowel obstruction (dilated loops of bowel)
- CT scan with IV, oral, and/or rectal contrast (sensitivity: 98%, specificity: 99%) to stage disease and determine treatment plan (2)[A]
- Ultrasound and MRI (sensitivity: 94%, specificity: 92%) are useful alternatives.
- Barium enema is not recommended due to risk of peritoneal extravasation.

Diverticular bleeding
- Anemia with bleeding
- Obtain coagulation panel for coagulopathy.

Diagnostic Procedures/Other
TREATMENT

GENERAL MEASURES

- Diverticulosis: outpatient therapy with fiber supplementation and/or bulking agents (psyllium) (>30 g/day) (2)[A]
- Uncomplicated diverticulitis: outpatient therapy (see exceptions below) with or without oral antibiotics. 1–2% of subjects require hospitalization for toxicity, septicemia, peritonitis, or failure of symptoms to resolve. Up to 30% of patients may require surgery at first episode of diverticulitis.
- Complicated diverticulitis: hospitalization, bowel rest, and IV antibiotics. Hinchey classification (severity):
  - Stage I: diverticulitis + confined paracolic abscess
  - Stage II: diverticulitis + distant abscess
  - Stage III: diverticulitis + purulent peritonitis
  - Stage IV: diverticulitis + fecal peritonitis
- Symptomatic improvement is expected within 2 to 3 days. Antibiotics should be continued for 7 to 10 days.
- Diverticular bleeding: 80% of cases resolve spontaneously.

MEDICATION

First Line

- Symptomatic diverticulosis: cyclical rifaximin 400 mg PO BID for 7 days every month or continuous mesalamine 800 mg PO BID (2)[C]
- Acute diverticulitis
  - The routine use of antibiotics in uncomplicated diverticulitis is controversial (2),(3)[C].
  - Outpatient oral antibiotics: Cover for anaerobes and gram-negative bacteria with:
    - A fluoroquinolone (ciprofloxacin 750 mg BID or levofloxacin 750 mg QD) plus metronidazole 500 mg TID (may use clindamycin if metronidazole intolerant) or
    - Trimethoprim/sulfamethoxazole DS BID plus metronidazole 500 mg TID
  - Treat for 7 to 10 days.
- Inpatient: Use IV antibiotics.
  - Monotherapy with a β-lactam/β-lactamase inhibitor: piperacillin/tazobactam (3,375 g IV QID) or ampicillin/sulbactam 3 g IV q6h or ertapenem (1 g IV QD)
  - Penicillin-allergic patient: quinolone (levofloxacin 750 mg IV QD plus metronidazole 500 mg IV TID)
  - Unresponsive or severe disease: imipenem or meropenem
  - Recurrences of acute diverticulitis may be decreased by using mesalamine ± rifaximin or probiotics.
– Consider vasopressin 0.2 to 0.3 U/min through selective intra-arterial catheter.

- **Precautions**
  - Avoid morphine and other opiates that may increase intraluminal pressure or promote ileus.
  - Increased fiber intake is not recommended in the acute management of diverticulitis.

### Second Line
- **Outpatient:** amoxicillin/clavulanate monotherapy (875/125 mg BID) (contraindicated in patients with clearance <30 mL/min) or moxifloxacin (400 mg PO QD) plus metronidazole (500 mg PO TID)
- **Severely ill inpatients:** ampicillin (500 mg IV q6h) + metronidazole (500 mg IV TID) + a quinolone or ampicillin + metronidazole + an aminoglycoside

### ISSUES FOR REFERRAL
- Acute diverticulitis patients should follow up with a gastroenterologist or surgeon after resolution of diverticulitis (6 to 8 weeks) for colonoscopy to exclude malignancy, fistula, strictures, or inflammatory bowel disease (2).
- Acute complicated diverticulitis should have appropriate surgical and critical care/infectious disease consultations.

### SURGERY/OTHER PROCEDURES
- **Acute diverticulitis**
  - Indications for emergent surgery: peritonitis, uncontrolled sepsis, perforation, obstruction
  - Hinchey I and II: consultation to interventional radiology to drain large abscesses (>4 cm)
  - Hinchey III or IV: may require surgery during the same hospital admission
  - Elective colon resection in recurrent diverticulitis is a case-by-case decision and is typically performed during the quiescent phase following appropriate nonoperative treatment (2).
  - Immunocompromised patients are more likely to present with acute complicated diverticulitis, fail medical management, and have complications from elective surgery.
- **Diverticular bleeding**
  - Endoscopy and hemostasis via epinephrine injection, electrocautery, or clipping
  - Angiography is preferred over endoscopy in unstable patients to identify the bleeding source and embolize the feeding artery.
  - Massive or recurrent bleeding requires limited or subtotal colectomy to control hemorrhage.

### COMPLEMENTARY & ALTERNATIVE MEDICINE
Probiotics have been used to prevent recurrence with mixed success.

### ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admit for systematic toxicity, sepsis, and/or peritonitis (complicated diverticulitis).
- Consider admitting patients with uncomplicated diverticulitis and the following: elderly, immunocompromised, evidence of microperforation, marked leukocytosis, temperature > 39 °C, intolerance of PO intake, severe abdominal pain, or unreliable follow up

### ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

**Patient Monitoring**
Follow up outpatients 2–3 days after initiating antibiotic therapy and then weekly thereafter until symptom resolution
Colonoscopy should be performed in 6–8 weeks (unless done within the past year)

**DIET**
- Bowel rest with NPO during acute diverticulitis; advance diet as tolerated as bowel function returns
- Patients with known diverticulosis or a history of diverticulitis should consume a high-fiber diet to prevent recurrence (3).
- Avoiding nuts and popcorn is not necessary (3).

**PROGNOSIS**
- Good with early detection and prompt treatment
- After first episode of diverticulitis, there is a 33% chance of recurrence. After a second episode, there is a 66% chance of further recurrence.
- Most complications occur during first bout of diverticulitis.
- Younger patients are more likely to have recurrence.
- Rebleeding occurs in up to 6%.

**COMPLICATIONS**
Hemorrhage, perforation, peritonitis, obstruction, abscess, or colovesicular/colovaginal fistula

**REFERENCES**

**ADDITIONAL READING**

**CODES**
ICD10
K57.90 Diverticlos of intest, part unsp, w/o perf or abscess w/o bleed
K57.30 Diverticlos of lg int w/o perforation or abscess w/o bleeding
K57.92 Diverticulitis of intestine, part unspecified, without perforation or abscess without bleeding

CLINICAL PEARLS

- Diverticulosis is common in elderly patients with a sedentary lifestyle who consume a Western diet.
- Patients with diverticulosis benefit from a high-fiber diet.
- Acute uncomplicated diverticulitis can be treated as outpatient with oral antibiotics. Acute complicated diverticulitis requires hospitalization, bowel rest, and IV antibiotics.
- Surgical consultation is recommended in all cases of acute complicated diverticulitis. Surgical intervention in diverticulitis and diverticular bleeding is a case-by-case decision.
- After an episode of diverticulitis, patients should undergo colonoscopy to rule out malignancy.
- Diverticular disease is a common cause of GI bleeding.
DOMESTIC VIOLENCE
Rhonda A. Faulkner, PhD • Luis T. Garcia, MD

BASICS

DESCRIPTION
- Domestic violence (DV) is the behavior in any relationship that is used to gain or maintain power and control over an intimate partner.
- May include physical, sexual, and/or emotional abuse; economic or psychological actions; or threats of actions that influence another person.
- Although women are at greater risk of experiencing DV, it occurs among patients of any race, age, sexual orientation, religion, gender, socioeconomic background, and education level.
- Synonym(s): intimate partner violence (IPV); spousal abuse; family violence

EPIDEMIOLOGY

Incidence
In the United States, lifetime estimates of DV are 22–39% of women, with 10–69% reporting physical assault by an intimate partner at some point in their lifetime. DV affects both sexes, but women are more likely to be victims than men and are more likely to report partner violence.

Prevalence
- DV occurs in 1 of 4 American families. Nearly 5.3 million incidents of DV occur each year among U.S. women aged ≥18 years and 3.2 million incidents among men.
- DV results in nearly 2 million injuries and up to 4,000 deaths annually in the United States.
- 14–35% of adult female patients in emergency departments report experiencing DV within the past year.
- Costs of DV are estimated to exceed $5.8 billion annually, of which $4.1 billion are for direct medical and mental health services.
- DV survivors have a 1.6- to 2.3-fold increase in health care use compared with the nonabused population.

Geriatric Considerations
- 4–6% of elderly are abused, with ~2 million elderly persons experiencing abuse and/or neglect each year. In 90% of cases, the perpetrator is a family member.
- Elder abuse is any form of mistreatment that results in harm or loss to an older person; may include physical, sexual, emotional, financial abuse, and/or neglect.

Pediatric Considerations
- >3 million children aged 3 to 17 years are at risk of witnessing acts of DV.
- ~1 million abused children are identified in the United States each year.
- Children living in violent homes are at increased risk of physical, sexual, and/or emotional abuse; anxiety and depression; decreased self-esteem; emotional, behavioral, social, and/or physical disturbances; and lifelong poor health.

Pregnancy Considerations
DV occurs during 7–20% of pregnancies. Women with unintended pregnancy are at 3 times
greater risk of DV. 25% of abused women report exacerbation of abuse during pregnancy. There is a positive correlation between DV and postpartum depression.

RISK FACTORS

- Patient/victim risk factors
  - Substance abuse
  - Poverty/financial stressors/unemployment/less education
  - Recent loss of social support
  - Family disruption and life cycle changes
  - Prior history of abusive relationships or experiencing abuse as child
  - Mental or physical disability in family
  - Social isolation
  - At-risk alcohol or drug use/high-risk sexual behavior
  - Pregnancy
  - Attempting to leave the relationship

- Perpetrator risk factors
  - Substance abuse (e.g., PCP, cocaine, amphetamines, alcohol)
  - Young age
  - Unemployment/recent job loss or instability
  - Low academic achievement
  - Witnessing or experiencing violence as child
  - Depression
  - Personality disorders
  - Threatening to self or others
  - Violence to children or violence outside the home
  - Owns weapons

- Relational risk factors
  - Marital conflict
  - Marital instability
  - Economic stress
  - Traditional gender role norms
  - Poor family functioning
  - Obsessive, controlling relationship

Geriatric Considerations
Factors associated with the abuse of older adults include increasing age, nonwhite race, low-income status, functional impairment, cognitive disability, substance use, poor emotional state, low self-esteem, cohabitation, and lack of social support. In 90% of cases, the perpetrator is a family member.

Pediatric Considerations
Factors associated with child abuse or neglect include low-income status, low maternal education, nonwhite race, large family size, young maternal age, single-parent household, parental psychiatric disturbances, and presence of a stepfather.

DIAGNOSIS
• DV is often underdiagnosed, with only 10–12% of physicians conducting routine screening.
• Although prevalence of DV in primary care settings is 7–50%, <15% are screened.
• Pregnancy increases risk
• Barriers to screening: time constraints, discomfort with the subject, fear of offending the patient, and lack of perceived skills and resources to manage DV
• Abused patients may refuse to disclose abuse for many reasons, which include the following:
  – Not feeling emotionally ready to admit the reality of the situation
  – Shame and self-blame
  – Feelings of failure if abuse is admitted
  – Fear of rejection by the physician
  – Fear of retribution from abuser
  – Belief that abuse will not happen again
  – Belief that no alternatives or available resources exist

HISTORY
• Physicians should introduce the subject of DV in a general way (i.e., “I routinely ask all patients about domestic violence. Have you ever been in a relationship where you were afraid?”).
• How to screen
  – Screen patient alone, without partner or others present.
  – Ask screening questions in patient’s primary language; do not use children or other family members as interpreters.
• Partner violence screen (sensitivity 35–71%; specificity 80–94%)
  – “Have you ever been hit, kicked, punched, or otherwise, hurt by someone within the past year? If so, by whom?”
  – “Do you feel safe in your current relationship?”
  – “Is there a partner from a previous relationship who is making you feel unsafe now?”
• Centers for Disease Control and Prevention (CDC)-recommended RADAR system
  – R: Routinely screen every patient; make screening a part of everyday practice in prenatal, postnatal, routine gynecologic visits, and annual health screenings.
  – A: Ask questions directly, kindly, and be nonjudgmental.
  – D: Document findings in the patient’s chart using the patient’s own words, with details. Use body maps and photographs as necessary.
  – A: Assess the patient’s safety and see if the patient has a safety plan.
  – R: Review options for dealing with DV with the patient and provide referrals.
• SAFE questions
  – Stress/safety: “Do you feel safe in your relationship?”
  – Afraid/abused: “Have you ever been in a relationship where you were threatened, hurt, or afraid?”
  – Friends/family: “Are your friends or family aware that you have been hurt? Could you tell them, and would they be able to give you support?”
  – Emergency plan: “Do you have a safe place to go and the resources you need in an emergency?”
• HITS questions: “How often does your partner:
  – Hurt you physically?
  – Insult or talk down to you?
  – Threaten you with harm?”
– Scream or curse at you?”

- Assess pregnancy difficulties such as poor/late prenatal care, low-birth-weight babies, and perinatal deaths.
- Pelvic and abdominal pain, chronic without demonstrable pathology
- Headaches, back pain
- Gynecologic disorders
- Sexually transmitted infections (STIs), including HIV/AIDS
- Depression, suicidal ideation, anxiety, fatigue
- Substance abuse
- Eating disorders
- Overuse of health services/frequent emergency room visits
- Noncompliance

**PHYSICAL EXAM**

- Clinical presentation/psychological signs and symptoms
  - Delay in seeking treatment
  - Inconsistent explanation of injuries
  - Reluctance to undress
  - Signs of battered woman syndrome and/or posttraumatic stress disorder (PTSD) (flat affect/avoidance of eye contact, evasiveness, heightened startle response, sleep disturbance, traumatic flashbacks)
  - Depression, anxiety, chronic fatigue, substance abuse
  - Suspicious partner accompaniment at appointment; overly solicitous partner and/or refusal to leave exam room

- Physical signs and symptoms
  - Tympanic membrane rupture
  - Rectal or genital injury (centrally located injuries with bathing-suit pattern of distribution—concealable by clothing)
  - Head and neck injuries (site of 50% of abusive injuries)
  - Facial scrapes, loose or broken tooth, bruises, cuts, or fractures to face or body
  - Knife wounds, cigarette burns, bite marks, welts with outline of weapon (such as belt buckle)
  - Broken bones
  - Defensive posture injuries
  - Injuries inconsistent with the explanation given
  - Injuries in various stages of healing

**DIAGNOSTIC TESTS & INTERPRETATION**

- The U.S. Preventive Services Task Force (USPSTF) in 2013 issued guidelines recommending that clinicians screen all women of childbearing age (14 to 46 years old) for DV and provide or refer women to intervention services when appropriate ([1][B]).

- Other recommendations
  - American College of Physicians (ACP) recommends routine screening for DV for all women in primary care settings at periodic intervals and when women present for emergency care with traumatic injuries.
  - The American Medical Association (AMA) recommends that all patients be routinely screened for DV with inquiry into history of family violence.
The World Health Organization (WHO) recommends against DV screening or routine inquiry about exposure to DV; however, they recommend asking about exposure to DV when assessing conditions that may be caused or complicated by abuse (2)[B].

U.S. Surgeon General and American Academy of Family Physicians recommend that physicians consider the possibility of DV as a cause of illness and injury.

The Partner Violence Screen is a three-question screening tool with a high specificity.

There is no evidence of harm in screening for DV.

**Pediatric Considerations**

American Academy of Pediatrics (AAP) and AMA recommend that physicians remain alert for signs and symptoms of child physical and sexual abuse in the routine exam.

**Pregnancy Considerations**

American College of Obstetrics and Gynecologists (ACOG) and AMA guidelines on DV recommend that physicians routinely assess all pregnant women for DV. ACOG recommends periodic screening throughout obstetric care (at the first prenatal visit, at least once per trimester, at the postpartum checkup).

**Initial Tests (lab, imaging)**

Liver function tests (LFTs), amylase, lipase if abdominal trauma is suspected

**TREATMENT**

- Treatment includes initial diagnosis; ongoing medical care; emotional support, counseling, and patient education regarding the DV cycle; referrals to community and supportive services as needed
- On diagnosis, use the SOS-DoC intervention:
  - **S**: Offer Support and assess Safety:
    - Support: “You are not to blame. I am sorry this is happening to you. There is no excuse for DV.”
    - Remind patient of your commitment to confidential communication.
    - Safety: Listen and respond to safety issues for the patient: “Do you feel safe going home?”; “Are your children safe?”
  - **O**: Discuss Options, including safety planning and follow-up:
    - Provide information about DV and help when needed. Make referrals to local resources:
      - “Do you need or want to access a safety shelter or DV service agency?”
      - “Do you want police intervention and if so, would you like me to call the police so they can make a report with you?”
      - Offer numbers to local resources and National DV Hotline: 1-800-799-SAFE (open 24/7; can provide physicians in every state with information on local resources).
  - **S**: Validate patient’s Strengths:
    - “It took courage for you to talk with me today. You have shown great strength in very difficult circumstances.”
  - **Do**: Document observations, assessment, and plans:
    - Use patient’s own words regarding injury and abuse.
    - Legibly document injuries: Use a body map.
    - If possible, take instant photographs of patient’s injuries if given patient consent.
Make patient safety plan. Prepare patient to get away in an emergency:

- Encourage patient to keep the following items in a safe place: keys (house and car); important papers (Social Security card, birth certificates, photo ID/driver’s license, passport, green card); cash, food stamps, credit cards; medication for self and children; children’s immunization records; important phone numbers/addresses (friends, family, local shelters); personal care items (e.g., extra glasses).
- Encourage patient to arrange a signal with someone to let that person know when she or he needs help.

- C: Offer Continuity:
  - Offer a follow-up appointment and assess barriers to access.

GENERAL MEASURES

- Reporting child and elder abuse to protective services is mandatory in most states. Several states have laws requiring mandatory reporting of IPV.
- Contact the local DV program to find out about laws and community resources before they are needed.
- Display resource materials (National DV Hotline: 1-800-799-SAFE) in the office, all exam rooms, and restrooms.

ADDITIONAL THERAPIES

- National DV Hotline: 1-800-799-SAFE (7233)
- Post in all exam rooms posters in both English and Spanish; available at http://www.thehotline.org/resources/download-materials/

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Schedule prompt follow-up appointment.
- Inquire about what has happened since last visit.
- Review medical records and ask about past episodes to convey concern for the patient and a willingness to address this health issue openly.
- DV often requires multiple interventions over time before it is resolved.

PATIENT EDUCATION

- Counsel patients about nonviolent ways to resolve conflict.
- Educate patients about the cycle of violence.
- Counsel parents about developmentally appropriate ways to discipline their children.
- Educate parents about the negative consequences of arguments on children and each other.
- National Coalition Against Domestic Violence: http://www.ncadv.org/
- CDC: http://www.cdc.gov/violenceprevention/

PROGNOSIS

Most DV perpetrators do not voluntarily seek therapy unless pressured by partners or on legal mandate. Current evidence is insufficient on effectiveness of therapy for perpetrators.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- T74.91XA Unspecified adult maltreatment, confirmed, initial encounter
- T74.11XA Adult physical abuse, confirmed, initial encounter
- T74.31XA Adult psychological abuse, confirmed, initial encounter

CLINICAL PEARLS

- Display resource materials in the office (e.g., posting abuse awareness posters/National DV Hotline, 1-800-799-SAFE, in both English and Spanish, in all exam rooms and restrooms).
- Given the high prevalence of DV and the lack of harm and potential benefits of screening, routine screening is recommended.
- For those who screened positive, offer resources, reassure confidentiality, and provide close follow-up.
DOWN SYNDROME
Michele Roberts, MD, PhD • Brian G. Skotko, MD, MPP

BASICS
DESCRIPTION
• Down syndrome (DS) is a congenital condition associated with intellectual disability and an increased risk of multisystem medical problems.
• Systems affected: neurologic (100%), cardiac (40–50%), GI (8–12%)
• Synonym: trisomy 21

Pediatric Considerations
Murmur may not be present at birth. Delay in recognition of heart condition may lead to irreversible pulmonary hypertension.

Geriatric Considerations
• Life expectancy has increased to ~60 years.
• Age-related health issues occur at earlier age than in the general population.
• Communication difficulties may interfere with prompt recognition of some medical issues.

Pregnancy Considerations
• American College of Obstetricians and Gynecologists (ACOG) recommends all pregnant women be offered traditional prenatal screening and diagnostic testing for DS.
  – Maternal prenatal screening may be performed in the 1st or 2nd trimester.
  – Prenatal diagnostic tests include chorionic villus sampling or amniocentesis.
• ACOG and the Society for Maternal-Fetal Medicine (SMFM) acknowledge that any women may choose noninvasive prenatal screening (NIPS). American College of Medical Genetics and Genomics (ACMG) recommends all women be offered NIPS (1,2).
• Most, but not all, men with DS are believed to be infertile.
• Most women with DS are subfertile but can conceive children with and without DS.

EPIDEMIOLOGY
Incidence
In the United States, 1/792 live births, ~5,300 births per year (3)

Prevalence
~206,000 persons in the United States (4)

ETIOLOGY AND PATHOPHYSIOLOGY
• Etiology: presence of all or part of an extra chromosome 21
• Trisomy 21: 95% of DS, an extra chromosome 21 is found in all cells due to nondisjunction, usually in maternal meiosis.
• Translocation DS: 3–4% of DS, extra chromosome 21q material is translocated to another chromosome (usually 13, 14, or 21); ~25% have parental origin.
• Mosaic trisomy 21: 1–2% of DS, manifestations may be milder.

Genetics
- Online Mendelian Inheritance in Man (OMIM) 190685
- Inheritance: most commonly sporadic nondisjunction resulting in trisomy 21
- Chance of having another child with DS is
  - 1% (or age risk, whichever is greater) after conceiving a pregnancy with nondisjunction trisomy 21
  - 10–15% for mothers/sisters and 3–5% for fathers/brothers who carry balanced translocation with chromosome 21
  - 100% if the parental balanced translocation is 21;21 (45,t[21;21])
  - Unclear after child with mosaic DS but ~1%

**RISK FACTORS**
- DS believed to occur in all races and ethnicities with equal frequency
- Chance of having an infant with DS increases with mother’s age
- Relatively more infants with DS are born to younger mothers because younger women are more likely to become pregnant.
- Prenatal diagnosis of DS is more common in older women, and a high percentage of such pregnancies are electively terminated.

**GENERAL PREVENTION**
- No prevention for nondisjunction trisomy 21
- Preimplantation diagnosis with in vitro fertilization (IVF), prenatal diagnosis followed by termination, and adoption are current options for expectant parents who do not wish to raise a child with DS.

**COMMONLY ASSOCIATED CONDITIONS**
- Cardiac
  - Congenital heart defects (40–50%)
- GI/growth
  - Feeding problems are common in infancy.
  - Structural defects (~12%)
  - Gastroesophageal reflux
  - Constipation
  - Celiac disease (~5%)
- Pulmonary
  - Tracheal stenosis/tracheoesophageal fistula
  - Pulmonary hypertension
  - Obstructive sleep apnea (50–75%)
- Genitourinary
  - Cryptorchidism, hypospadias
- Hematologic/neoplastic
  - Transient myeloproliferative disorder (~10%): generally resolves spontaneously; can be preleukemic (acute megakaryoblastic leukemia [AMKL]) in 20–30%
  - Leukemia (AMKL or acute lymphoblastic leukemia [ALL]) in 0.5–1%
  - Decreased risk of most solid tumors; increased risk of germ cell tumors/testicular cancer
- Endocrine
  - Hypothyroidism: congenital or acquired (13–63%)
  - Diabetes
Skeletal
- Atlantoaxial instability (15%): ~2% symptomatic
- Short stature is common.
- Scoliosis (some cases have adult onset)
- Hip problems (1–4%)

Immune/rheumatologic
- Abnormal immune function with increased rate of respiratory infections
- Increased risk of autoimmune disorders, including Hashimoto thyroiditis, celiac disease, and alopecia

Neurologic
- Intellectual ability ranging from mild to severe disability. Average is moderate intellectual disability.
- Autism spectrum disorder (<18%)
- Seizures (8%); typically occurring <1 year of age (infantile spasms) or >30 years of age
- Alzheimer disease: At least 40% at age 40 years develop signs of dementia; percentage increases with age.

Psychiatric
- Attention deficit hyperactivity disorder (ADHD), obsessive-compulsive disorder (OCD), and autism spectrum disorder increased frequency in children.
- Generalized depression and anxiety with increased frequency in young adults/adults

Sensory
- Hearing loss (75%): mostly conductive due to high frequency of asymptomatic middle ear effusion; otitis media (50–70%)
- Visual impairment (60%): strabismus (refractive errors, 15%), myopia, hyperopia, nystagmus, cataracts (15%)

Dermatologic
- Xerosis, eczema, palmoplantar hyperkeratosis, atopic or seborrheic dermatitis, onychomycosis, syringomas, furunculosis/folliculitis, hidradenitis suppurativa

DIAGNOSIS
HISTORY
~85% of mothers of infants with DS learn of the diagnosis postnatally, although this is changing with the availability of NIPS.

PHYSICAL EXAM
- In November 2015, DS-specific growth charts were released. They describe recent growth trends in a sample of children with DS in the United States. These charts can be used as screening tools to help better assess growth and nutritional trends of children with DS, who grow differently from their typically developing peers; these charts do not represent “optimal” growth of children with DS; 50% BMI on the DS-specific growth curves corresponds to the 85% (overweight) on the standard NCHS growth curves (5).
- Infants and children
  - Brachycephaly (100%)
  - Hypotonia (80%)
  - Small ears, often low set and simplified
– Upslanting palpebral fissure (90%)
– Epicantthic folds (90%)
– Brushfield spots
– Depressed nasal bridge
– Short neck, often with increased nuchal folds
– Single palmar crease, single flexion crease on 5th finger
– Increased space between toes 1 and 2, 5th finger clinodactyly, brachydactyly

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Maternal prenatal screening includes the following:
– 1st trimester: combined screen (maternal age, β-human chorionic gonadotropin [β-hCG], pregnancy-associated plasma protein A [PAPP-A], and nuchal translucency)
– 2nd trimester: quad screen (α-fetoprotein, β-hCG, estriol, inhibin A)
– Sequential screen (combined screen in 1st trimester, if abnormal, obtain amniocentesis or await 2nd trimester quad screening)
– Integrated screen (combined screening in 1st trimester plus quad screen in 2nd trimester)
– NIPS with cell-free DNA (beginning ~10 weeks’ gestation) (1,2)

Prenatal diagnosis includes the following:
– Chorionic villus sampling: 1st trimester, ~99% accurate, ~1% miscarriage rate
– Amniocentesis: 2nd trimester, ~99% accurate, ~0.25% miscarriage rate

Postnatal diagnosis
– Fluorescence in situ hybridization (FISH) can be performed at time of clinical suspicion, but karyotype should always be done to differentiate type of DS.
– Parental (and adult-age sibling) karyotype is indicated only if translocation DS found in child.

Labs for newborns
– Echo, with or without murmur
– CBC with differential (to look for transient myeloproliferative disorder)
– Thyroid-stimulating hormone (TSH)
– Audiogram
– Ophthalmologic exam (look for red reflex)
– Swallowing study for those with feeding difficulties

Follow-Up Tests & Special Considerations

After delivering a prenatal diagnosis, the clinician should offer “Understanding a Down Syndrome Diagnosis” (http://understandingdownsyndrome.org).

If the diagnosis is postnatal, the mother and her partner should be informed of the diagnosis promptly by a physician (preferably the obstetrician and pediatrician or family physician), on the basis of clinical observations and before the karyotype is available, but with consideration of extenuating circumstances (e.g., mother’s medical condition). The spouse/partner and infant should be present unless this would cause undue delay. The meeting should be private. Refer to the baby by name.

In the postnatal setting, the clinician should be knowledgeable on the subject of DS and should conduct a discussion with content that is current, respectful, balanced, informative, and realistic but not overly pessimistic, concentrating on what is relevant to the 1st year of life.

Cardiac follow-up, as indicated
TREATMENT

GENERAL MEASURES
Genetic evaluation and counseling

ISSUES FOR REFERRAL
- Infant stimulation programs (Early Intervention)
- Lactation consultant
- Physical/occupational/speech therapy
- Educational inclusion supported by federal law
- Pediatric cardiologist, if indicated
- DS specialty clinics can improve medical outcomes.

SURGERY/OTHER PROCEDURES
Repair of congenital anomalies is appropriate. Plastic surgery for facial features is not recommended.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- There is no evidence to support the use of antioxidant or folinic acid supplements in children with DS.
- Craniosacral manipulation is dangerous due to potential atlantoaxial instability.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
If the social situation indicates adoption, consider the National Down Syndrome Adoption Network (NDSAN) (http://www.ndsan.org/) national registry of families seeking to adopt a child with DS.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
The American Academy of Pediatrics recommends ongoing assessment and review, at least annually, of the following surveillance:
- Vision: Assess for strabismus, cataracts, and nystagmus by ophthalmologist by 6 months, annually between ages 1 and 5 years, every 2 years ages 5 to 13 years, every 3 years ages 13 to 21 years.
- Hearing: neonatal screen with auditory brainstem response (ABR) or otoacoustic emissions (OAE), then audiogram every 6 months until age 3 years, and then annually
- Thyroid: initial newborn screen. Repeat TSH at 6 months, 12 months, and then annually (5) [C].
- Screening for celiac disease (total IgA and tissue transglutaminase [tTG]-IgA) annually, if symptomatic
- Three-view cervical spine films if patient symptomatic, beginning at 3 to 5 years of age
- Hemoglobin annually to screen for iron deficiency anemia
- Repeat echocardiogram in teens if with murmur or fatigue.
- Integrating specific aspects of DS care into the electronic health record can improve adherence.
DIET
- No special diet, but caloric needs are lower in adolescents/adults with DS than their peers.
- Obesity is prevalent at all ages.
- No scientific evidence supports megavitamin therapy or dietary supplements.

PATIENT EDUCATION
- The LuMind IDSC Down Syndrome Foundation provides information on the latest research for people with DS: www.lumindidsc.org
- Lettercase provides peer-reviewed booklet for parents who have received a prenatal diagnosis of DS and have not yet made a decision about their pregnancy: https://www.lettercase.org/.
- Down Syndrome Pregnancy provides free downloadable books and articles for expectant mothers who have decided to continue their pregnancies after a prenatal diagnosis of DS: http://downsyndromepregnancy.org/.
- Understanding a Down Syndrome Diagnosis provides an overview of DS and select resources: http://understandingdownsyndrome.org/.

PROGNOSIS
- Associated congenital anomalies are the immediate concern during the newborn period.
- 99% of young adults/adults with DS report being happy with their lives.
- Life expectancy ~60 years

REFERENCES

ADDITIONAL READING
CLINICAL PEARLS

- Down syndrome (DS) is a congenital condition associated with intellectual disability and an increased risk of multisystem medical problems including neurologic, cardiac, and GI.
- Inheritance: most commonly sporadic nondisjunction resulting in trisomy 21
- 99% of young adults/adults with DS report being happy with their lives.
- DS specialty clinics may improve medical outcomes.
DRUG ABUSE, PRESCRIPTION
Pamela R. Tsinteris, MD, MPH ● Matthew A. Silva, PharmD, RPh, BCPS

BASICS
Controlled substances are prone to misuse and diversion. Universal precautions should be used for monitoring of all patients prescribed controlled substances to identify substance use disorder in affected patients. Patients with substance use disorder should be offered treatment (and/or referred as needed).

DESCRIPTION
- Prescription drug abuse behaviors exist on a continuum and may include:
  - Use of medication for nonmedical reasons such as to get high or enhance performance
  - Use of medication for medical reasons other than what the prescriber intended
  - Use of medication for any reason by someone other than the person for whom the medication was originally prescribed
- Commonly abused prescription medications include opioid analgesics (morphine, oxycodone, hydrocodone, oxymorphone, hydromorphone, fentanyl, methadone, buprenorphine), stimulants (amphetamine, methylphenidate), benzodiazepines (alprazolam, clonazepam, lorazepam), and barbiturates (secobarbital, amobarbital).
- Diversion is a term used to describe the rerouting of medications from prescriptions or other legitimate supplies for recreational use or criminal activity, such as selling prescription medication for personal profit.

EPIDEMIOLOGY
- More than half of ED-related visits are related to abused or misused pharmaceuticals (opioid and nonopioid).
- In the U.S. in 2016, there were 17,087 overdose deaths involving prescription opioids, which account for 27% of all drug overdose deaths that year.
- Prescription opioid abuse is the strongest predictor of heroin initiation and use.

Incidence
- Predominant sex: males > females
- Predominant age: highest among adults 18 to 25 years (mean 22 years), then adolescents and teens 12 to 17 years, followed by adults ≥26 years

Prevalence
- Lifetime prevalence of prescription drug abuse is highest for opioids, benzodiazepines, and stimulants.
- In the U.S. in 2016, the Centers for Disease Control and Prevention (CDC) found that 4.3% reported misuse of prescription pain relievers, 2.1% for prescription stimulants, 2.2% for prescription tranquilizers, and 0.6% for prescription sedatives.

ETIOLOGY AND PATHOPHYSIOLOGY
Opioids, benzodiazepines, stimulants, and barbiturates produce euphoria, tolerance, and
dependence leading to misuse and addiction.

**Genetics**

Variant alleles affect the expression and function of opioid, dopamine, acetylcholine, serotonin, and γ-aminobutyric acid, helping to explain susceptibility to different forms.

**RISK FACTORS**

- Sociodemographic, psychiatric, pain, and drug-related factors
- Genetics, environment, family history
- Ongoing opioid prescription (3+ months) greatly increases risk of opioid-related overdose at 1 year (4-fold) and 5 years (30-fold).

**GENERAL PREVENTION**

- Limit or avoid prescribing controlled medications on the first visit (until the relationship is established).
- Take a thorough history, review records, and perform periodic urine drug screens (UDSs) before deciding if a controlled substance is indicated.
- Try all available nonopioid treatments for pain before prescribing opioids for chronic pain.
- Avoid prescribing benzodiazepines. Use other treatments for anxiety (cognitive-behavioral therapy, mindfulness, selective serotonin reuptake inhibitors, PRN H1 blocker, buspirone).
- Avoid benzodiazepines and hypnotics in elderly.
- Patients should give good informed consent about risks of controlled medications before starting AND every 3 months while continuing treatment.
- Develop/adopt standard practice agreements for prescribing and monitoring controlled substances.
- Wean/stop prescription analgesics for chronic pain if ineffective for improving pain and function, if aberrant behaviors suggesting opioid use present, or if patient overdoses.
- Dose reduction of chronic opioids can decrease risk while improving pain, function, and quality of life.
- Prescription monitoring programs (PMPs) reduce doctor shopping but not ED visits for overdose and prescription drug abuse–related deaths.
- Identify and treat underlying substance use disorder.
- Prescribe intranasal naloxone to all patients prescribed chronic opioids and provide education to patient and family members on proper use in case of overdose.

**COMMONLY ASSOCIATED CONDITIONS**

- Opioids: tolerance (loss of effectiveness over time), opioid-induced hyperalgesia, dependence (uncomfortable withdrawal), addiction (which can lead to loss of savings, job, close relationships and incarceration, hepatitis C virus or HIV infection, etc.), overdose/death, depression, constipation, low testosterone, and sexual dysfunction.
- Benzodiazepines and barbiturates: dependence (withdrawal can cause seizures, delirium tremens, death), psychosis, anxiety, sleep driving, blackout states, cognitive impairment, impaired driving; increased fall risk and mortality in elderly patients
- Stimulants: dependence, hypertension, tachyarrhythmias, myocardial ischemia, seizures, hypothermia, psychosis, hallucinations, paranoia, anxiety
**DIAGNOSIS**

- Initial screening: “How many times in the past year have you used an illegal drug or used a prescription medication for nonmedical reasons?”; primary care setting sensitivity of 100% and specificity of ~75% (1)[C]
- Other screening tools: Drug abuse screening test (DAST) helps determine involvement with drugs over the past year. Assess alcohol use with CAGE or Alcohol Use Disorders Identification Test (AUDIT).

**HISTORY**

Consider aberrant behaviors when taking a history. Patient may ask for dose escalations and early refills (“spilled the bottle . . .,” “pharmacist shorted me . . .,” etc.). Patients may have a strong preference for one drug, make appointments at end of day and after hours, and/or show hostile/threatening or flattering behavior.

**PHYSICAL EXAM**

- Monitor patients for signs of sedation, confusion, or intoxication (can include slurred speech and unsteady gait in case of benzodiazepines).
- Physical exam findings in opioid withdrawal include dilated pupils, frequent yawning, tachycardia, elevated blood pressure, and piloerection. Physical exam findings in benzodiazepine withdrawal include tachycardia, elevated blood pressure, and tremors.
- There are often no physical exam findings during a visit when a patient is misusing a prescription medication, other objective findings such as urine drug testing should be used in monitoring.

**DIAGNOSTIC TESTS & INTERPRETATION**

UDSs are recommended to identify nonadherent patients (2)[C]. Random pill counts are useful for identifying patients misusing, abusing, or diverting medication

**Initial Tests (lab, imaging)**

- Urine Drug Screens (UDS’s): Order an expanded panel to detect commonly used opioids (specifically ask for semisynthetics [hydrocodone, hydromorphone, oxycodone] and synthetics [methadone, fentanyl, propoxyphene, meperidine] along with tramadol and buprenorphine. Also test for other drugs of abuse such as benzodiazepines, cocaine, amphetamine, alcohol metabolite, and consider other drugs that may be highly prevalent in your area (such as gabapentin, PCP, barbiturates).
- Oxycodone (OxyContin) will be positive for oxycodone and oxymorphone.
- Hydrocodone will be positive for hydrocodone and hydromorphone.
- Codeine will be positive for codeine plus morphine.
- Heroin will be positive for morphine and 6-acetylmorphine if very recent use. Codeine can also be seen as metabolite of common impurities found in heroin.
- If the UDS is positive for morphine, it could mean ingestion of morphine, codeine, or heroin.

**Follow-Up Tests & Special Considerations**

Random pill counts are useful for identifying patients taking more controlled substance than prescribed. Random urine drug testing can also be concurrently collected.

**Test Interpretation**
Screening drug tests (by enzyme-linked immunosorbent assay method) may result in false positives from interactions with other commonly prescribed medications or substances people are frequently exposed to (such as energy drinks causing a false positive amphetamine screen), so treatment decisions should be based on highly specific confirmation testing (such as by gas chromatography/mass spectrometry).

Full opioid metabolite table: https://cdn.jamanetwork.com/ama/content_public/journal/jama/936574/jdt170008t2.png?Expires=2147483647&Signature=OOcIxDK9eppBxWxAv4J87uDPrKcTMP32FF3xvFC34Ixovlc1uRCHWtcRK77jZtbfQQLZWHmKG6i6bM-ELulZJbivg7h0IvrazcqJkkD2Zdk8cjfoIL0ibydVQsBaOYcF6SYHzzRdioxhXCad1v280~7a~8VMNjEpWkfr4FzgxKCP169g__&Key-Pair-Id=APKAIE5G5CRDK6RD3PGA

Results are positive if drugs (or metabolites of drugs) that are not prescribed are present; positive in presence of illicit drugs (e.g., cocaine). Suspect diversion when negative for prescribed drug at a time when the patient reported taking it. Ingestion of poppy seeds can cause positive morphine and codeine on urine drug screen confirmation testing. Advise patients prescribed controlled substances to avoid eating poppy seeds to avoid confusion from this.

**TREATMENT**

Addiction is a treatable chronic disease. The general approach to treatment includes inpatient, residential, or outpatient detoxification as required; counseling and intensive counseling as needed; and ongoing medication-assisted treatment (MAT) with buprenorphine or injectable naltrexone.

**ALERT**

Begin taper to initiate discontinuation whenever there is evidence of prescription opioid abuse (2)[C]. Some situations indicate immediate discontinuation rather than taper (e.g., diversion or plan to switch to buprenorphine treatment).

- Opioid discontinuation through interdisciplinary pain care programs, buprenorphine-assisted programs, and detoxification programs have achieved opioid discontinuation rates >85%.
- Benzodiazepines cannot be stopped abruptly for risk of seizures and death. Discontinue via slow taper or at a controlled detoxification program.
- Amphetamines can be stopped abruptly without risk of severe withdrawal or death.

**GENERAL MEASURES**

A variety of treatments are available including inpatient programs (detoxification and sometimes induction onto MAT), outpatient programs (MAT and behavioral health) and peer-led support services.

**MEDICATION**

- Short-term opioid detoxification programs use clonidine, buprenorphine, or methadone under the direction of an addiction specialist.
- Long-term MAT with buprenorphine/naloxone, methadone, or naltrexone is more effective than short-term detoxification.
Buprenorphine/naloxone and methadone are similarly effective when used in long-term opioid maintenance therapy, and both are effective in the treatment of chronic pain for people with opioid dependence.

Only an addiction specialist may dispense methadone for treatment of opioid use disorder at a certified opioid treatment program.

Any provider (MD, DO, NP, or PA) may prescribe buprenorphine/naloxone after completing training and obtaining an X waiver. For details, see https://www.samhsa.gov/medication-assisted-treatment/buprenorphine-waiver-management.

Buprenorphine/naloxone should be continued as long as the patient takes prescribed doses and remains engaged in care; discontinue if there is evidence of buprenorphine/naloxone diversion. The use of buprenorphine/naloxone with benzodiazepines, alcohol, and stimulants is risky but safer than buprenorphine/naloxone with other full-dose opioid agonists.

Buprenorphine/naloxone doses should be titrated to the maximum of 24 mg/day for patients who continue to use other opioids. Methadone or detoxification followed by naltrexone should be recommended for those unable to abstain from opioids on maximal buprenorphine/naloxone dosing.

Buprenorphine/naloxone formulations discourage misuse (such as by sniffing or IV) because naloxone displaces buprenorphine binding to opioid receptors when taken parenterally (naloxone is not well absorbed sublingually).

Buprenorphine without naloxone is more prone to misuse. Previously recommended for use in pregnant patients because of concern for possible fetal harm from naloxone. There is newer evidence that buprenorphine/naloxone is safe for the fetus, and many clinicians prescribe the combined product in pregnancy.

Buprenorphine is now also available as a monthly long-acting injectable into the subcutaneous tissue of the abdomen, which improves adherence and avoids diversion.

The opioid antagonist naltrexone (oral or long-acting injectable) reduces cravings for opioids and blocks opioid-euphoria when ingested and does not require special training to prescribe. Naltrexone should not be started until a full 7-day wash-out is ensured to avoid precipitating severe withdrawal. This wash-out requirement for injectable naltrexone means fewer patients will be successful starting buprenorphine/naloxone, but once started, effectiveness of injectable naltrexone is similar.

There is no objective evidence for using or converting to long half-life benzodiazepines before beginning a slow benzodiazepine taper, although diazepam is often preferred. Carbamazepine may be useful in patients dependent on ≥20 mg diazepam equivalents daily. Antidepressants may be helpful for depression and anxiety linked to benzodiazepine withdrawal. There are no specific benefits shown using propranolol, buspirone, progesterone, or hydroxyzine to manage withdrawal symptoms.

Atomoxetine, guanfacine, and bupropion SR can also be helpful in managing attention deficit hyperactivity disorder (ADHD) symptoms in select patients.

First Line
Treatment plans should be adjusted to fit patient needs. Some patients are able to achieve remission on their own, with peer support or with behavioral health support alone but many require MAT. The best medication is the medication that the patient will take.

Second Line
See above
ISSUES FOR REFERRAL
Enlist the help of chemical dependency groups/addiction specialists, pain management, and psychiatry/psychology when patients have polysubstance abuse and to treat underlying mood and anxiety disorders, posttraumatic stress disorder, and ADHD.

ADDITIONAL THERAPIES
- Behavioral health support (individual counseling, group therapy, which may include a variety of clinical approaches). This can also be available as intensive outpatient programs and partial hospitalization programs.
- Smart Recovery and 12-step programs such as AA and NA.
- Residential treatment programs (range in length from acute detoxification, short-term rehabilitation, transitional support programs, crisis stabilization units, to long-term residential programs including halfway houses and sober houses)
- Al-Anon/Alateen and Learn to Cope provide helpful free support groups for family members.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Mindfulness and meditation, acupuncture, or yoga may help with stress reduction.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Indications for inpatient detoxification include concomitant alcohol and benzodiazepine dependence (increased risk of seizures), mental confusion/delirium, history of seizures, psychosis, suicidal ideation, serious, or absence of social support.

ONGOING CARE
Treatment with MAT should continue for as long as the patient benefits from it.

FOLLOW-UP RECOMMENDATIONS
Expert opinion suggests high frequency visits (such as weekly) when a patient begins MAT.

Patient Monitoring
Monitor patients with in-person check-ins, drug testing, and review of the PMP.

PATIENT EDUCATION
- Controlled medication should be inaccessible to others (ideally in locked box/bag). Diverting medication may result in legal charges.
- Red flags, dose escalation, stress, cravings, and preoccupation about the next dose

PROGNOSIS
The majority of patients with substance use disorder are able to achieve remission.

COMPLICATIONS
Misuse of opioids and benzodiazepines may lead to overdose and death. Misuse of stimulants may lead to psychosis and cardiac conditions such as myocardial infarction and arrhythmias.

REFERENCES

SEE ALSO

CODES
ICD10
- F19.10 Other psychoactive substance abuse, uncomplicated
- F11.10 Opioid abuse, uncomplicated
- F15.10 Other stimulant abuse, uncomplicated

CLINICAL PEARLS
- Perform informed consent about all risks of controlled substances before starting and every 3 months while prescribing.
- Conduct frequent UDSs (weekly to every 3 months) for all patients prescribed controlled substances.
- Discontinue prescription opioid analgesics if pain or functionality does not improve or if there is evidence of abuse or diversion (e.g., positive UDSs, driving while intoxicated [DWI], overdose, early refills).
- Limit benzodiazepine use to short-term use.
- “How many times in the past year have you used an illegal drug or prescription medication for nonmedical reasons?”
- Buprenorphine/naloxone is an effective treatment for opioid use disorder.
  Buprenorphine/naloxone can be used to chronic pain in those with opioid dependence.
- Other MATs for opioid use disorder include naltrexone (no special training required) and methadone.
**DUCTAL CARCINOMA IN SITU**
Bradley M. Turner, MD, MPH, MHA, FCAP, FASCP • David G. Hicks, MD

---

### BASICS

#### DESCRIPTION
- Ductal carcinoma in situ (DCIS) is a heterogeneous group of lesions that have in common the presence of a clonal proliferation of neoplastic, noninvasive epithelial cells confined to ducts and lobules.
- Considered a premalignant lesion
- Classified as low, intermediate, or high grade
- Mortality from DCIS with subsequent progression to invasive breast carcinoma (IBC) is low, regardless of histologic type or type of treatment.

#### EPIDEMIOLOGY

**Incidence**
- Average annual percentage increase of 1%
- Estimated 62,117 new diagnoses of DCIS in 2018
- Estimated 62,738 new diagnoses of DCIS in 2019
- DCIS accounts for approximately 80–85% of in situ breast carcinomas (lobular carcinoma in situ [LCIS] accounts for approximately 15–20%).
- More stable incidence in women 50 to 69 years old
- Increasing incidence in women <50 and >70 years old
- Represents ~26% of all new IBC
- Incidence rate comparable in different ethnicities

#### ETIOLOGY AND PATHOPHYSIOLOGY
- A nonobligate precursor to IBC
- Poorly understood spectrum of polyclonal and clonal epithelial proliferative lesions—final step prior to IBC
- The changes necessary for transition to IBC are poorly understood.
- Molecular evidence suggests that low- and high-grade DCIS are genetically distinct lesions, with high-grade DCIS associated with more aggressive disease.

#### Genetics
- Low-grade DCIS typically expresses estrogen receptor (ER) and progesterone receptor (PR), without HER2 protein overexpression or amplification.
- High-grade DCIS not consistently ER+ or PR+; frequent HER2 protein overexpression and amplification (even more frequent compared to IBC); commonly associated with p53 gene mutations
- BRCA1 and BRCA2 associations observed
- Consider genetic counseling in high-risk DCIS patients.

#### RISK FACTORS
Similar to IBC, although not as strongly associated
Female gender, nulliparity, late age at first birth or menopause, first-degree relative with breast cancer, long-term use of postmenopausal combined estrogen and progestin therapy, high breast density, history of atypical ductal hyperplasia (ADH)
Association with age, body mass index, smoking, lactation, early menarche, alcohol consumption, and oral contraceptive use is less clear.

GENERAL PREVENTION
Controversy exists because studies have suggested that screening may result in overdiagnosis with little or no reduction in the incidence of advanced cancers.
General screening guidelines suggested for asymptomatic women with an average risk
Women with increased risk should have more aggressive screening (risk assessment tool available at https://bcrisktool.cancer.gov/).
General screening guidelines—U.S. Preventive Services Task Force (USPSTF):
  – Biennial mammography for women aged 50 to 74 years (B recommendation)
  – The decision to start screening mammography in women <50 years should be an individual one.
  – If a higher value is placed on potential benefit, consider beginning biennial screening between 40 and 49 years of age (C recommendation).
  – Insufficient evidence regarding benefits and harms of screening mammography if ≥75 years old
  – Insufficient evidence to assess the benefits and harms of digital breast tomosynthesis (DBT) as a primary screening method (I statement)
  – Insufficient evidence to assess the balance of benefits and harms of adjunctive screening using breast ultrasonography, magnetic resonance imaging (MRI), DBT, or other methods in women identified to have dense breasts on an otherwise negative screening mammogram (I statement)
General screening guidelines—National Comprehensive Cancer Network (NCCN):
  – Women should be familiar with their breasts and promptly report changes; periodic consistent BSE may facilitate breast self-awareness.
  – Age 25 to 39 years: breast awareness, clinical breast exam (CBE) every 1 to 3 years
  – Age ≥40 years: breast awareness, annual CBE, annual screening mammography
Clinical judgment when applying screening guidelines
Mammography screening should be individualized.
If no intervention would occur based on screening findings, patient should not undergo screening.
Risk reduction:
  – Assess familial/genetic history.
  – Lifestyle modifications: Limit alcohol intake to <1 drink per day, exercise, maintain healthy diet, and weight control.
  – Risk reduction surgery supported for carefully selected women at high risk of breast cancer
  – Hormonal risk reduction agents (i.e., tamoxifen) recommended in certain high-risk women ≥35 years old
  – Benefits of aromatase inhibitors are less clear.
  – Recent clinical trial with anastrozole (an aromatase inhibitor) significantly decreased incidence of DCIS in postmenopausal women.
DIAGNOSIS

HISTORY
- Most DCIS is now diagnosed by screening mammography (presence of microcalcifications in approximately 72%); patients may be asymptomatic with nonpalpable mass (12%).
- More advanced lesions may present with a palpable mass, spontaneous nipple discharge, or Paget disease.

PHYSICAL EXAM
- CBE with patient in upright and supine position; evaluating for asymmetry, spontaneous discharge, skin changes (peau d’orange, erythema, scaling); nipple retraction/excoriation (Paget disease)
- Palpation of all breast quadrants, including lymph node examination (axillary, supraclavicular, and internal mammary nodes)
- Positive clinical findings: Refer for consideration of diagnostic imaging and/or surgical evaluation unless <30 years old with a low clinical suspicion (observe 1 to 2 menstrual cycles; refer if clinical findings persist).

DIFFERENTIAL DIAGNOSIS
Usual ductal hyperplasia, flat epithelial atypia, ADH, LCIS, microinvasive carcinoma

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Mammography Breast Imaging Reporting and Data System (BI-RADS: categories 0 to 6) is used for uniform reporting of mammography results.
- Interpretation and screening recommendations:
  - 0: needs additional imaging: diagnostic workup with consideration for diagnostic imaging
  - 1: negative: screening recommendations
  - 2: benign findings: screening recommendations
  - 3: probably benign finding: diagnostic imaging at 6 months, every 6 to 12 months for 2 to 3 years; consider biopsy if patient anxious or follow-up uncertain.
  - 4: suspicious: diagnostic imaging with follow-up
  - 5: highly suggestive of malignancy: diagnostic imaging with follow-up
  - 6: known biopsy-proven malignancy: NCCN guidelines for breast cancer should be followed.
- Similar for diagnostic ultrasound (US)
- DCIS seen as clustered microcalcifications
- Diagnostic imaging will result in consideration for tissue biopsy.

Follow-Up Tests & Special Considerations
- US not recommended for screening
- Sensitivity of breast MRI screening > mammography with < specificity resulting in > false positives
- Screening MRI only recommended in certain women:
  - BRCA mutation—commence at age 25 to 29 years
  - First-degree relative of BRCA carrier—commence at age 25 to 29 years
  - ≥20% lifetime risk of breast cancer defined by models that are largely based on family
history—annual breast MRI to begin 10 years prior to the youngest family member but not prior to age 25 years
- Thoracic radiation between the ages of 10 and 30 years—annual breast MRI to begin 10 years after radiation therapy but not prior to age 25 years
- Presence of Li-Fraumeni, PTEN, or Bannayan-Riley-Ruvalcaba syndrome in patient or first-degree relative
- ≥20% risk of breast cancer based on gene and/or risk level: ATM, CDH1, CHEK2, PALB2, PTEN, STK11, TP53

- Insufficient evidence to recommend for or against MRI screening in the following groups: 15–20% lifetime risk of breast cancer, defined by models that are largely based on family history; heterogeneous or extremely dense breast tissue on mammography; personal history of breast cancer or DCIS
- Screening with MRI is not recommended in women with <15% lifetime risk of breast cancer.
- MRI can also complement mammography in patients with skin changes.
- Although MRI and US are complementary diagnostic methods to mammography, US is less sensitive in detecting most microcalcifications and MRI does not typically detect microcalcifications at all.
- After a diagnosis of DCIS, MRI has been prospectively shown to have a sensitivity of up to 98% for high-grade DCIS (1)[A].
- The NCCN Panel has included breast MRI as indicated during the initial workup of DCIS, noting that the use of MRI has not been shown to increase the likelihood of negative margins or decrease the conversion to mastectomy with DCIS.

Pathology
- Tissue is necessary for diagnosis: typically core needle (CN) or vacuum-assisted (VA) biopsy (mammographic/stereotactic, US, or MRI guided). Open surgical biopsy can be performed in patients not amenable to CN or VA biopsy.
- Fine-needle aspiration (FNA) is not adequate for specific diagnosis of DCIS; however, it can suggest the presence of neoplastic cells.
- Histologic classification
  - Classification is subjective; however, traditionally classified as either low, intermediate, or high based on architectural patterns (comedo, solid, cribriform, clinging, papillary, and micropapillary), nuclear grade (I, II, or III), and the absence or presence of necrosis
  - Ductal intraepithelial neoplasia (DIN) is an alternative histologic classification incorporating size as a discriminating factor.
  - Grade is more important for prognosis, risk for progression, and local recurrence.
  - Comedo-type necrosis (necrosis filling central portion of involved duct) is typically seen in high-grade DCIS, with varying degrees of necrosis in other types of DCIS.
- Determination of ER and PR status (1)[A]
- Studies show unclear or weak evidence of HER2 status as a prognostic indicator in DCIS.

**TREATMENT**

**SURGERY/OTHER PROCEDURES**
- Surgery is the primary treatment option. Options for surgery are based on risk of recurrence,
anatomic location, extent of disease, and the ability to achieve “negative” margins (1)[A].

- Positive margins are considered “ink on tumor.”
- Totality of evidence does not support the routine practice of obtaining negative margin widths wider than 2 mm (1)[C].

- Margins <1 mm considered inadequate (1)[A]
- Margins <1 mm at the breast fibroglandular boundary (chest wall or skin) do not mandate surgical excision but may be an indication for higher boost dose radiation in patients opting for breast conservation (1)[A].
- DCIS with microinvasion, defined as no invasive focus >1 mm in size, should be considered as DCIS when considering the optimal margin width (1)[C]. When there is only minimal or focal DCIS involvement near the margin, clinical judgment can be applied to determine if reexcision might be avoided in individual cases (1)[C].

- Surgical options include the following:
  - Breast conservation (lumpectomy) without lymph node procedure, without breast radiation therapy (1)[A]
  - Breast conservation (lumpectomy) without lymph node procedure, with whole breast radiation therapy, with or without boost to tumor bed (1)[A]
  - A complete axillary lymph node dissection should not be performed in the absence of evidence of invasive cancer or proven axillary metastatic disease (1)[A].
  - A sentinel lymph node biopsy may be considered if the lumpectomy is in an anatomic location compromising the performance of a future sentinel lymph node procedure (1)[C].
  - Radiation decreases recurrence rates by about 50% but with limited overall survival benefit.
  - ~50% of recurrences are pure DCIS; ~50% are IBC (1)[A].
  - Drawbacks to radiation therapy include (i) the patient’s burden of daily treatment for 6 weeks and short-term side effects, such as fatigue and skin toxicity; (ii) a slightly increased risk of secondary cancers; and (iii) inability to receive radiation therapy again in the ipsilateral breast should an invasive carcinoma develop.
  - Recurrence generally requires mastectomy with consideration for systemic treatment.
  - Patients not amenable to margin-free lumpectomy should have total mastectomy (1)[C].
  - Mastectomy with or without sentinel node biopsy plus optional breast reconstruction (1)[A]
  - Mastectomy provides maximum local control.
  - Rates of recurrence for DCIS and IBC are similar to lumpectomy.
  - Recurrence should be treated with wide local excision, chest wall radiation, and consideration for systemic treatment (1)[A].
  - Long-term cause-specific survival seems to be equivalent to lumpectomy with whole breast radiation (1)[A].
  - A sentinel lymph node biopsy may also be considered in patients with seemingly pure DCIS to be treated with mastectomy (1)[C].

- Secondary chemoprevention following breast-conserving surgery for ER + DCIS:
  - Tamoxifen for premenopausal patients or tamoxifen or an aromatase inhibitor for postmenopausal patients for 5 years
  - There may be some advantage for aromatase inhibitor therapy in patients <60 years old or patients with concerns for thromboembolism (1)[C].
  - Considered in lumpectomy patients with or without whole breast radiation (1)[A]
  - Benefit of tamoxifen and trastuzumab in ER-negative/HER2-positive disease is unclear.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- History and physical exam every 6 to 12 months for the first 5 years and then annually
- Mammography every 12 months (first mammogram 6 to 12 months after breast conservation therapy) \( (1)[C] \)
- If treated with tamoxifen or an aromatase inhibitor, monitor per NCCN guidelines for breast cancer risk reduction \( (1)[C] \).

PROGNOSIS

- Good prognosis: 10-year breast cancer–specific survival rates of >95%; overall mortality after diagnosis of treated pure DCIS generally >98%
- Risk of local recurrence after mastectomy generally reported as 1–2% (higher in some studies)
- Higher risk of local recurrences after breast-conserving therapy in younger age (particularly before age 40 years), larger tumor size, high nuclear grade, comedo-type necrosis, and close/positive margin status (related to DCIS volume)
- ER+ tumors are associated with lower risk for recurrence.
- There is interest in identifying subsets of patients who have low rates of ipsilateral breast tumor recurrence such that they might safely forgo radiation. The Oncotype DX DCIS test may help clinicians in selecting which patients with DCIS might safely forgo radiation therapy after breast-conserving surgery \( (2)[C] \). The test results in an Oncotype DX DCIS score, with the following risk categories: DCIS score <39 (low risk of recurrence; radiation therapy benefits likely to be small and will not outweigh the risks of side effects); DCIS score 39 to 54 (intermediate risk of recurrence; radiation therapy benefits unclear relative to the risks of side effects); DCIS score 55 to 100 (high risk of recurrence; radiation therapy benefits are likely to be greater than the risks of side effects)

REFERENCES

SEE ALSO

Breast Cancer
CODES

ICD10
- D05.10 Intraductal carcinoma in situ of unspecified breast
- D05.11 Intraductal carcinoma in situ of right breast
- D05.12 Intraductal carcinoma in situ of left breast

CLINICAL PEARLS

- DCIS is a heterogeneous group of noninvasive neoplastic breast ductal epithelial cell lesions.
- The incidence of DCIS has continued to increase in women <50 and >70 years of age, with a more stable incidence in women 50 to 69 years of age.
- The goal of DCIS treatment is to prevent recurrence and progression to IBC.
- The Oncotype DX DCIS score may help clinicians in selecting which patients with DCIS might safely forgo radiation therapy after breast-conserving surgery.
- Current standard of care is breast-conserving therapy with consideration for postoperative whole breast radiation therapy and/or postsurgical tamoxifen or aromatase inhibitor therapy, unless otherwise contraindicated.
- With appropriate therapy, the overall prognosis of pure DCIS is good.
DUPUYTREN CONTRACTURE
Rebecca M. King, MD ● Karl T. Clebak, MD, FAAFP ● Shawn F. Phillips, MD, MSPT

BASICS

DESCRIPTION
- Palmar fibromatosis; caused by progressive fibrous proliferation and tightening of the fascia of the palms, resulting in flexion deformities and loss of function
- Not the same as “trigger finger,” which is caused by thickening of the distal flexor tendon
- Similar change rarely occurs in plantar fascia, usually appearing simultaneously.
- System(s) affected: musculoskeletal
- Dupuytren diathesis is an aggressive form that has ectopic involvement of knuckle pads, plantar fibromatosis (Ledderhose – 10%), and penile fibromatosis (Peyronie – 2%).
- Synonyms: morbus Dupuytren; Dupuytren disease; “Celtic hand;” Viking’s disease; palmar fascial fibromatosis, contracture of palmar fascia

EPIDEMIOLOGY

Prevalence
- Increases with age; mean prevalence in Western countries: 12%, 21%, and 29% at ages 55, 65, and 75 years, respectively. Norway: 30% of males >60 years; Spain: 19% of males >60 years
- More common in Caucasians of Scandinavian or Northern European ancestry
- Mean age of onset is 60 years.

ETIOLOGY AND PATHOPHYSIOLOGY

Unknown; possibly oxidative stress, altered wound repair, and/or abnormal immune response. Occurs in three stages:
- Proliferative phase: proliferation of myofibroblasts with nodule development on palmar surface
- Involutional stage: spread along palmar fascia to fingers with cord development
- Residual phase: spread into fingers with cord tightening and contracture formation

Genetics
- Autosomal dominant with incomplete penetrance:
  – Siblings with 3-fold risk
- 68% of male relatives of affected patients develop disease at some time.
- Possible association with human leukocyte antigen alleles

RISK FACTORS
- Smoking (mean 16 pack-years, odds ratio: 2.8)
- Increasing age
- Male/Caucasian; male > female (range 3.5:1 to 9:1)
- Vibration exposure and manual work—risk doubles if regular (weekly) exposure
- Diabetes mellitus (DM) (increases with duration of DM, usually mild; middle and ring finger involved)
- Epilepsy
- Chronic illness (e.g., pulmonary tuberculosis, liver disease, HIV)
- Hypercholesterolemia
- Excessive alcohol consumption
- Northern European ethnicity
- Family history
- Hand trauma
- Low body weight and body mass index

GENERAL PREVENTION
Avoid risk factors, especially if a strong family history.

COMMONLY ASSOCIATED CONDITIONS
- Alcoholism
- Epilepsy (inconstant data)
- DM
- Chronic lung disease
- Occupational hand trauma (vibration)
- Hypercholesterolemia
- Carpal tunnel syndrome
- Peyronie disease
- HIV
- Cancer
- Adhesive capsulitis of shoulder

DIAGNOSIS

HISTORY
- Caucasian male, aged 50 to 60 years
- Family history
- Mild pain early:
  - Begins in palm and spreads to digits
- Unilateral or bilateral (50%)
- Right hand more frequent
- Ring finger or little finger most common, but any digit can be involved
- Ulnar digits more affected than radial digits
- Flexion contracture of metacarpophalangeal (MCP) before proximal interphalangeal (PIP) joint

PHYSICAL EXAM
- Painless plaques or nodules in palmar fascia
- Cordlike band in the palmar fascia
- Skin adheres to fascia and becomes puckered.
- Palpable subcutaneous nodules
- Reduced flexibility of MCP and PIP joints
- No sign of inflammation
- Web space contractures
Knuckle pads over PIP
  – Garrod nodes associated with severe disease

Disease stages:
  – Early: skin pits (can also be seen in nevoid basal cell cancer and palmar keratosis)
  – Intermediate: nodules and cords. Nerves and vessels can be entwined in cords.
  – Late: contractures

DIFFERENTIAL DIAGNOSIS
  ● Camptodactyly: early teens; tight fascial bands on ulnar side of small finger
  ● Diabetic cheiroarthropathy: all four fingers
  ● Volkmann ischemic contracture
  ● Trigger finger
  ● Ganglion cyst

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other
Diagnosis based on history and physical, testing is not routinely indicated. MRI can assess cellularity of lesions that correlate with recurrence after surgery.

Test Interpretation
  ● Myofibroblasts predominate.
  ● Nodules: Lumps fixed to skin hypercellular masses
  ● Cords: organized collagen type III arranged parallel and hypocellular
  ● First stage (proliferative): increased myofibroblasts
  ● Second stage (residual): dense fibroblast network
  ● Third stage (involutional): Myofibroblasts disappear.

TREATMENT

GENERAL MEASURES
  ● Physical therapy alone is ineffective:
    – Intermittent splinting is unlikely to be effective.
    – Continuous splinting may help pre- and postop.
  ● Follow isolated involvement of palmar fascia conservatively.
  ● MCP joint involvement can be followed conservatively if flexion contracture is <30 degrees.

MEDICATION
First Line
  ● Clostridial collagenase injections (FDA-approved 2010):
    – Degrades collagen to allow manual rupture of diseased cord
    – Best for isolated cord of MCP joint
    – 5-year recurrence rate of 47%; comparable with surgical recurrence rates (1)[B]
    – More rapid recovery of hand function compared to limited fasciectomy with fewer serious adverse events (2)[B]
    – Complications: injection site reaction, skin tear
    – Can do two cords concurrently
Can be effective for postsurgical recurrence

Steroid injection:
– Can treat acute nodules or painful knuckle pads
– Serial triamcinolone injections improved long-term outcomes when combined with needle aponeurotomy (3)[B].
– Steroid alone associated with 50% recurrence in 1 to 3 years

**Second Line**
Surgery for contracture >30%

**ISSUES FOR REFERRAL**
- Any involvement of PIP joints
- MCP joints contracted >30 degrees
- Impaired function
- Progressively worsening contracture
- Disabling deformity

**ADDITIONAL THERAPIES**
Percutaneous and needle fasciotomy:
- Best for MCP joint; improvement of 93% versus 57% for PIP joint
- Recurrence common; 50%
- Shown to be effective for recurrent disease
- Better for MCP joints in patients with comorbid conditions; lower complication rate, but higher recurrence
- At 3 months and 1 year, outcomes of needle fasciotomy and collagenase injections are the same (4)[B].

**SURGERY/OTHER PROCEDURES**
- Dermofasciectomy/limited fasciectomy/segmental aponeurectomy:
  - Greater initial correction over nonincisional treatment; higher complication rates
  - Percutaneous aponeurotomy and lipofilling (PALF) is a new, minimally invasive procedure that appears to have shorter convalescence, less long-term complications, similar operative contraction correction, and no significant difference at 1 year in results versus limited fasciectomy (5)[A].

- Indications:
  - Any involvement of the PIP joints
  - MCP joints contracted at least 30 degrees
  - Positive Hueston tabletop test (Patient is unable to lay palm flat on a table.)
- May require skin grafts for wound closure with severe cutaneous shrinkage
- 80% have full range of movement with early surgery.
- Amputation of 5th digit if severe and deforming
- MCP joints respond better to surgery than PIP joints, especially if contracted >45 degrees.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Patient Monitoring
Regular follow-up every 6 months to 1 year

PATIENT EDUCATION
- Avoid risk factors (alcohol, vibratory exposure, etc.), especially if strong family history.
- Mild disease: Passively stretch digits twice a day and avoid recurrent gripping of tools.

PROGNOSIS
- Unpredictable but usually slowly progressive
- 10% may regress spontaneously.
- Dupuytren diathesis predicts aggressive course. Features include ethnicity (Nordic), family history, bilateral lesions outside of palm, age <50 years—all factors with 71% risk of recurrence compared to baseline 23% without any risk factors.
- Prognosis better for MCP versus PIP joint after surgery and collagenase injection

COMPLICATIONS
- Complex regional pain syndrome
- Operative nerve injury
- Postoperative recurrence in 46–80%
- Postoperative hand edema and skin necrosis
- Digital infarction
- Limited hand function

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**

M72.0 Palmar fascial fibromatosis [Dupuytren]

**CLINICAL PEARLS**

- Dupuytren contracture is a fixed flexion deformity of (most commonly) the 4th and 5th digits due to palmar fibrosis. 90% of cases are progressive; not trigger finger, which is due to thickening of the distal flexor tendon
- Refer patients with involvement of the PIP joints or MCP involvement with contractures of >30 degrees.
- Both surgical and enzymatic fasciotomy have high rate of recurrence.
BASICS

DESCRIPTION
- A common chronic dermatitis often involving the palms and soles. The precise definition is frequently debated, with many terms being used interchangeably. Efforts are being made to more specifically define dyshidrosis, and literature supports the presence of several different classes within the family “dyshidrosis.”
  - Dyshidrotic eczema
    - Common, chronic, or recurrent; nonerythematous; symmetric vesicular eruption primarily of the palms, soles, and interdigital areas
    - Associated with burning, itching, and pain
  - Pompholyx (from Greek “bubble”)
    - Rare condition characterized by abrupt onset of large bullae
    - Often used interchangeably with dyshidrotic eczema (small vesicles); however, may be a distinct entity
  - Lamellar dyshidrosis
    - Fine, spreading, exfoliation of the superficial epidermis in the same distribution as described above

System(s) affected: dermatologic, exocrine, immunologic
Synonym(s): cheiropompholyx, keratolysis exfoliativa, vesicular palmoplantar eczema, desquamation of interdigital spaces pompholyx, acute and recurrent vesicular hand dermatitis

EPIDEMIOLOGY

Incidence
- Mean age of onset is 40 years and younger.
- Male = female
- Comprises 5–20% of hand eczema cases

Prevalence
20 cases per 100,000 people

ETIOLOGY AND PATHOPHYSIOLOGY
- Exact mechanism unknown; thought to be multifactorial (allergies, genetics, and dermatophyte infection implicated)
  - Dermatopathology: intraepidermal spongiosis without effect on eccrine sweat glands
  - Vesicles remain intact due to thickness of stratum corneum of palmar/plantar skin (1).
  - Immunologic reaction: theorized that rapid rise in immunoglobulin levels may precipitate vesicle formation
  - Aggravating factors (debated)
    - Hyperhidrosis (in 40% of patients with the condition)
    - Detergents/solvents
- Increased water exposure (e.g., florists, hair stylists, health care workers)
- Climate: hot/cold weather; humidity
- Contact sensitivity (in 30–67% of patients with the condition) (2)
- Metals: nickel, cobalt, and chromate sensitivity (may include implanted orthopedic or orthodontic metals) (1)
- Stress
- Dermatophyte infection (present in 10% of patients with the condition) (2)
- Prolonged wear of occlusive gloves
- Cement workers
- IV immunoglobulin therapy
- Smoking
- Sunlight/UVA radiation

**Genetics**
- Atopy: 50% of patients with dyshidrotic eczema have atopic dermatitis (1).
- Rare autosomal dominant form of pompholyx found in Chinese population maps to chromosome 18q22.1–18q22.3 (2)

**RISK FACTORS**
- Many risk factors are disputed in the literature, with none being consistently associated.
- Atopy
- Other dermatologic conditions
  - Atopic dermatitis (early in life)
  - Contact dermatitis (later in life)
  - Dermatophytosis
- Sensitivity to
  - Foods
  - Drugs: neomycin, quinolones, acetaminophen, and oral contraceptives
  - Contact and dietary: nickel (more common in young women), chromate (more common in men), and cobalt (1)
  - Smoking

**GENERAL PREVENTION**
- Control emotional stress.
- Avoid excessive sweating.
- Avoid exposure to irritants.
- Avoid diet high in metal salts (chromium, cobalt, nickel).
- Avoid smoking.

**COMMONLY ASSOCIATED CONDITIONS**
- Atopic dermatitis
- Allergic contact dermatitis
- Parkinson disease
- HIV (2)
HISTORY
- Episodes of pruritic rash
- Recent emotional stress
- Familial or personal history of atopy
- Exposure to allergens or irritants
  - Occupational, dietary, or household
  - Cosmetic and personal hygiene products
  - Vesicular eruption typically occurs 24 hours after allergen challenge (1).
- Costume jewelry use
- IV immunoglobulin therapy
- HIV
- Smoking

PHYSICAL EXAM
- Transient, often recurrent, symmetrical vesicular eruptions located on volar and plantar surfaces and lateral fingers. Lesions may not heal completely between flares (1).
- Prodrome: Intense pruritus may occur prior to vesicular eruption.
- Early findings
  - 1 to 2 mm, clear, nonerythematous, deep-seated vesicles (lasting 2 to 3 weeks)
  - Has a “tapioca” appearance
- Late findings
  - Unroofed vesicles with inflamed bases
  - Desquamation (terminal phase)
  - Peeling, rings of scale, or lichenification common

DIFFERENTIAL DIAGNOSIS
- Vesicular tinea pedis/manuum
- Vesicular id reaction
- Contact dermatitis (allergic or irritant)
- Scabies
- Chronic vesicular hand dermatitis
- Drug reaction
- Dermatophytid
- Bullous disorders: dyshidrosiform bullous pemphigoid, pemphigus, bullous impetigo, epidermolysis bullosa (3)
- Pustular psoriasis
- Acrodermatitis continua
- Erythema multiforme
- Herpes simplex infection
- Pityriasis rubra pilaris
- Vesicular mycosis fungoides

DIAGNOSTIC TESTS & INTERPRETATION

Follow-Up Tests & Special Considerations
- Skin culture in suspected secondary infection (most commonly, Staphylococcus aureus) (4)
- Consider antibiotics based on culture results and severity of symptoms.
**Diagnostic Procedures/Other**
- Diagnosis is based on clinical exam.
- Potassium hydroxide (KOH) wet mount (if concerned about dermatophyte infection)
- Patch test (if suspecting allergic cause) (4)

**Test Interpretation**
- Fine, 1- to 2-mm spongiotic, intraepidermal vesicles with little to no inflammatory change
- No eccrine glandular involvement
- Thickened stratum corneum

**TREATMENT**

**GENERAL MEASURES**
- Avoid possible causative factors: stress, direct skin contact with irritants, nickel, occlusive gloves, household cleaning products, smoking, sweating.
- Use moisturizers/emollients for symptomatic relief and to maintain effective skin barrier (4).
- Skin care
  - Avoid shoes with known irritants (i.e., leather, rubber soles, etc.).
  - Wear socks and gloves made of cotton and change frequently.
  - Wash infrequently in lukewarm water, carefully dry, and then apply emollient.
  - Avoid direct contact with fresh fruit (5)[C].

**MEDICATION**

**First Line**
- Mild cases: topical steroids (high potency) (2)[B]
  - Considered cornerstone of therapy but limited published evidence
  - Limited use for 2 weeks due to risk of infection (4)[B]
- Moderate to severe cases
  - Ultra high-potency topical steroids with occlusion over treated area (4)[B]
  - Prednisone 40 to 100 mg/day tapered after blister formation ceases (2)[B]
    - Limited use due to significant side effects (4)[B]
  - Psoralens plus ultraviolet (UV)-A (PUVA) therapy, either systemic/topical or immersion in psoralens (2)[B]
- Recurrent cases (4)[B]
  - Systemic steroids at onset of itching prodrome
  - Prednisone 60 mg PO for 3 to 4 days

**Second Line**
- Topical calcineurin inhibitors (mitigate the long-term risks of topical steroid use)
  - Topical tacrolimus (6)[B]
  - Topical pimecrolimus (6)[B]
  - May not be as effective on plantar surface
- Other therapies (typically with dermatology consultation)
  - Oral cyclosporine (4)[B]; monitor for hypertension and renal injury.
  - Injections of botulinum toxin type A (BTXA) (6)[B]
    - Newer topical forms of BTXA currently being developed show promise.
- Painful, requires nerve block
  - Systemic alitretinoin (teratogenic) (5)[B]
  - Topical bexarotene (a teratogenic retinoid X receptor agonist approved for use in cutaneous T-cell lymphoma) (6)[B]
  - Methotrexate (6)[C] (significant side effects including GI intolerance and hepatotoxicity) (4)[B]
  - Azathioprine (1)[C] (6- to 8-week onset of action; must monitor for GI side effects, liver toxicity, blood dyscrasia)
  - Disulfiram or sodium cromoglycate in nickel-allergic patients (1)[C]
  - Mycophenolate mofetil (2)[C] (GI side effects; benefit: no hepatotoxicity with long-term use) (4)[B]
  - Tap water iontophoresis (2)[C]

**ISSUES FOR REFERRAL**
- Allergist (if allergen testing required)
- Psychologist (if stress modification needed)

**ADDITIONAL THERAPIES**
- Other oral agents:
  - Thalidomide (do not use in pregnancy/no available studies on efficacy)
  - Dapsone 100 to 150 mg daily (also limited literature on efficacy; may be used in combination with steroids) both significant side effects; very limited use (4)[B]
- Radiation therapy (1)[C]
- UV-free phototherapy (5)[C]
- Treat underlying dermatophytosis (1).
- BTXA in those in which excessive sweating is an exacerbating factor (4)[B]

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Conservative management:
  - Antihistamines: hydroxyzine, cetirizine, loratadine
  - Soaks/cold compresses of weak solutions of potassium permanganate, Burow solution (aluminum acetate), or vinegar 15 minutes, 4 times daily (4)[C]
- Exposure to sunlight as maintenance therapy, 12 minutes every other day, 10 to 15 exposures (5)[C]
- Dandelion juice (avoid in atopic patients) (6)[C]
- Cognitive relaxation techniques (4)[B]

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Dyshidrotic Eczema Area and Severity Index (DASI) (1)
- Parameters used in the DASI score
  - Number of vesicles per square centimeter
  - Erythema
  - Desquamation
- Severity of itching
- Surface area affected
- Grading: mild (0 to 15), moderate (16 to 30), severe (31 to 60)
- Monitor BP and glucose in patients receiving systemic corticosteroids.
- Monitor for adverse effects of medications.

**DIET**
- Consider diet low in metal salts if there is history of nickel sensitivity (4)[B].
- Updated recommendations for low-cobalt diet are available (1).

**PATIENT EDUCATION**
- Instructions on self-care, complications, and avoidance of triggers/aggravating factors
- American Academy of Dermatology: dyshidrotic eczema at: https://www.aad.org/public/diseases/eczema/dyshidrotic-eczema#overview

**PROGNOSIS**
- Condition is benign.
- Usually heals without scarring
- Lesions may spontaneously resolve.
- Recurrence is common.

**COMPLICATIONS**
- Quality of life impact: skin tightening, pain, and decreased dexterity
- Secondary bacterial infections with or without steroid use (S. aureus most common)
- Dystrophic nail changes
- Fissures and ulcerations
- Psychological distress
- Lymphedema

Algorithm: Rash

CODES
ICD10
L30.1 Dyshidrosis [pompholyx]

CLINICAL PEARLS
- Dyshidrosis is a transient, recurrent, vesicular eruption, most commonly of the palms, soles, and interdigital areas.
- Etiology and pathophysiology are unknown but are most likely related to a combination of genetic and environmental factors.
- Best prevention is effective skin care and limiting exposure to irritating agents.
- Treatments are based on disease severity; preferred treatments include topical steroids, oral steroids, and calcineurin inhibitors.
- Condition, although benign and self-healing, can be chronic and debilitating with major concern for superimposed bacterial infection that may be avoided by preventative measures, early treatment, and recognition.
DYSMENORRHEA
Maggie C. Wertz, MD

BASICS

DESCRIPTION
- Pelvic pain occurring at/around time of menses; a leading cause of absenteeism for women <30 years old
- Primary dysmenorrhea: pelvic pain without pathologic physical findings
- Secondary dysmenorrhea: often more severe, results from specific pelvic pathology; severity based on activity impairment
  - Mild: painful, rarely limits daily function, or requires analgesics
  - Moderate: daily activity affected, rare absenteeism, requires analgesics
  - Severe: daily activity affected, likelihood of absenteeism increased, limited benefit from analgesics
- System affected: reproductive
- Synonym(s): menstrual cramps

EPIDEMIOLOGY
- Predominant age
  - Primary: onset 6 to 12 months after the start of menarche, teens to early 20s
  - Secondary: 20s to 30s
- Predominant sex: women only

Prevalence
- Up to 90% of menstruating females have experienced primary dysmenorrhea (1).
- Up to 42% lose days of school/work monthly due to dysmenorrhea.
- Up to 20% reported impairment in daily activities and/or sleep.

ETIOLOGY AND PATHOPHYSIOLOGY
- Primary: Elevated prostaglandin (PGF2α) production through indirect hormonal control (decrease in progesterone at start of menses leads to increase in prostaglandins) causes nonrhythmic hypercontractility and increased uterine muscle tone with vasoconstriction and resultant uterine ischemia. Ischemia results in hypersensitization of type C pain nerve fibers; intensity of cramps directly proportional to amount of PGF2α released (1)
- Secondary
  - Endometriosis (most common cause)
  - Adenomyosis
  - Congenital abnormalities of uterine/vaginal anatomy
    - Cervical stenosis
  - Pelvic inflammatory disease
  - Ovarian cysts
  - Pelvic tumors, especially leiomyomata (fibroids) and uterine polyps

Genetics
Not well studied
RISK FACTORS
- Primary (1,2)
  - Cigarette smoking
  - Alcohol use
  - Early menarche (age <12 years)
  - Age <30 years
  - Family history of dysmenorrhea
  - Irregular/heavy menstrual flow
  - Nonuse of oral contraceptives
  - Sexual abuse/history of sexual assault
  - Psychological symptoms (depression, anxiety, increased stress, etc.)
  - Nulliparity
- Secondary
  - Pelvic infection
  - Use of intrauterine device (IUD) in the few months following insertion
  - Structural pelvic malformations
  - Family history of endometriosis in first-degree relative

GENERAL PREVENTION
- Primary: regular exercise; early childbirth
- Secondary: Reduce risk of sexually transmitted infections (STIs).

Pediatric Considerations
Onset with first menses raises probability of genital tract anatomic abnormality (i.e., transverse vaginal septum, imperforate or minimally perforated hymen, uterine anomalies).

COMMONLY ASSOCIATED CONDITIONS
- Irregular/heavy menstrual periods
- Longer menstrual cycle length/duration of bleeding
- Anxiety/depression
- Decreased quality of life

DIAGNOSIS
Based on characteristic history of suprapubic/low back cramping/pain occurring at or near menstrual flow onset lasting for 8 to 72 hours (2)

HISTORY
- Primary: onset once ovulatory cycles are established in adolescents; 6 to 12 months after menarche on average
- Patients may have associated nausea, vomiting, diarrhea, headache, fatigue, insomnia, pain radiating into the low back or inner thighs, and rarely syncope and fever. These are all considered to be secondary to prostaglandin release.
- Recurrence at or just before the onset of the menstrual flow
  - Pelvic pain occurring between menstrual periods is not likely to be dysmenorrhea.
  - Present with most menstrual periods (cyclic)
- Relief associated with the following:
– Use of analgesics, especially NSAIDs
– Local heat application
– Orgasm

* Response to NSAIDs helps confirm diagnosis.
* Impact of symptoms on daily activities can help determine severity.
* Secondary: associated with chronic pelvic pain, midcycle pain, dyspareunia, abnormal uterine bleeding, typical onset after age 25 years, nonmidline pain, progression of severity, lack of response to NSAIDs/hormonal treatment and infertility

**PHYSICAL EXAM**

* Primary: Physical exam typically is normal. Examine to rule out secondary dysmenorrhea only if the history is inconsistent with primary dysmenorrhea. Pelvic exam is recommended if patient is sexually active to rule out infection.
* Secondary: Evaluate for cervical discharge, uterine enlargement, tenderness, irregularity, or fixation.

**DIFFERENTIAL DIAGNOSIS**

* Primary: History is characteristic.
* Secondary
  – Endometriosis (most common)
  – Pelvic/genital infection
  – Complication of pregnancy
  – Missed/incomplete abortion
  – Ectopic pregnancy
  – Uterine/ovarian neoplasm
  – UTI
  – Complication with IUD use
  – Congenital uterine or cervical anomaly
  – Adenomyosis
  – Leiomyomata (fibroids)
  – Pelvic adhesions
  – Inflammatory bowel disease
  – Irritable bowel syndrome
  – Chronic pelvic pain (idiopathic)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

All tests should only be performed if indicated based on history or if patient has symptoms refractory to first-line therapies; most cases of primary dysmenorrhea can be diagnosed on history alone.

* Pregnancy test
* Urine testing for infection
* Gonorrhea/chlamydia cervical testing, especially in women age <25 years and in high-prevalence areas

* Primary: Consider pelvic ultrasound to rule out secondary abnormalities.
* Secondary: ultrasound and/or laparoscopy to define anatomy for severe/refractory cases. MRI may be useful as second-line noninvasive imaging if ultrasound is nondiagnostic and fibroids,
ovarian torsion, deep endometriosis, or adenomyosis is suspected.

**Follow-Up Tests & Special Considerations**
Counsel regarding appropriate preventive measures for STI and pregnancy.

**Diagnostic Procedures/Other**
Laparoscopy is rarely needed and is usually only considered in cases of suspected endometriosis or pelvic adhesions not definitively identified on transvaginal ultrasound.

**Test Interpretation**
- Primary: none
- Secondary: Specific anatomic abnormalities may be noted (see “Differential Diagnosis”).

**Pregnancy Considerations**
Consider ectopic pregnancy when pelvic pain occurs with vaginal bleeding in a patient with a positive pregnancy test.

**TREATMENT**
- Reassure the patient that treatment success is very likely with adherence to recommendations.
- Relief may require the use of several treatment modalities at the same time.

**GENERAL MEASURES**
- Exercise (3)[B] and local heat (1)[A] are noninvasive general measures to relieve pain. Local heat in conjunction with the use of an NSAID is superior to an NSAID alone (1)[A].
- High-frequency transcutaneous electrical nerve stimulation (TENS) has been found to be beneficial (1,4)[A]. Low-frequency TENS is not recommended because it is not superior to placebo.
- Secondary dysmenorrhea: treatment of suspected/confirmed underlying cause of pain

**MEDICATION**

**First Line**
- NSAIDs: inhibit the peripheral production of prostaglandins. No NSAID has been found to be superior to others (5)[A]. Medication should be taken on scheduled dosing 1 to 2 days prior to onset of menses and continued for 2 to 3 days (1,2,5)[A]. If one NSAID preparation does not work, another NSAID preparation should be tried. Each preparation should be taken as prescribed for at least 3 menstrual cycles prior to determining effectiveness.
  - Ibuprofen 400 mg PO q8h
  - Naproxen sodium 500 mg PO q12h
  - Celecoxib 400 mg PO × 1 and then 200 mg PO q12h
  - Mefenamic acid 500 mg PO × 1 and then 250 mg PO q6h
- Hormonal contraceptives: recommended for primary dysmenorrhea in women desiring contraception (2)[B]. Directly suppresses ovulation and limits endometrial growth resulting in reduced prostaglandin production, intrauterine pressure, and uterine contractions. Continuous rather than cyclic dosing has been found to be superior for pain control (4)[A]. Estrogen-containing contraceptives are recommended first line for secondary dysmenorrhea due to endometriosis, although progestin-only methods have also been shown to be beneficial (2)[B].
– Low-dose and high-dose combined oral contraceptives (COCs) along with transdermal and intravaginal combined contraceptives have all been found to be superior to placebo (1)[A].
– Levonorgestrel IUDs are just as effective as COCs (4)[A].
– Progestin-only contracections including subcutaneous and subdermal preparations appear to decrease primary dysmenorrhea but to a lesser extent than combined options and IUDs (1,2) [B].

- Potential contraindications to NSAIDs and COCs
  – Platelet disorders
  – Gastric ulceration or gastritis
  – Personal and family history of thromboembolic disorders
  – Vascular disease
  – Migraines with aura
  – Active smoking
- Precautions for all first-line options:
  – GI irritation
  – Lactation
  – Coagulation disorders
  – Impaired renal function
  – Heart failure
  – Liver dysfunction
  – Pregnancy
  – Hypertension
- Significant possible interactions
  – Coumadin-type anticoagulants
  – Aspirin with other NSAIDs

**Second Line**
- Acetaminophen and acetaminophen with caffeine are superior to placebo and have less side effects than NSAIDs (1)[B].
- Behavioral interventions, such as relaxation exercises including yoga, may help alleviate pain in primary dysmenorrhea.
- Nifedipine may be effective in some women and may be used in women trying to conceive (pregnancy Category C).

**SURGERY/OTHER PROCEDURES**
Laparoscopic uterosacral nerve ablation and presacral neurectomy have been shown to relieve pain at 6 and 12 months, respectively, but are still reserved for patients with pain resistant to all other first-line and second-line treatments (1,4)[B].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Chinese herbal medicine shows promising evidence of decreasing pain, but more evidence is needed.
- Acupuncture treatments have been shown to decrease pain in dysmenorrhea, but further randomized, well-designed studies are needed. Additionally, these treatments must be frequent and timely for effectiveness.
- Acupoint stimulation, particularly noninvasive stimulation (acupressure), has had inconclusive results for pain relief.
• Aromatherapy abdominal massage performed daily for 10 minutes, 7 days prior to onset of menses can decrease primary dysmenorrhea.
• Further research needed to determine benefit and safety for regular use of oral fennel, oral ginger, oral fenugreek, oral valerian, extracorporeal magnetic innervation, vitamin K\textsubscript{1} injection into the spleen-6 acupuncture point, use of high-frequency vibratory stimulation tampon, transdermal nitroglycerin, and vaginal sildenafil.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Both primary and secondary dysmenorrhea are usually managed in the outpatient setting.

- Primary: outpatient care
- Secondary: usually outpatient care

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Normal

**DIET**
Insufficient evidence for any specific dietary changes

**PATIENT EDUCATION**
Reassure the patient that primary dysmenorrhea is treatable with the use of NSAIDs, COCs, IUD, or local heat, and that it will usually abate with age and parity.

**PROGNOSIS**
- Primary: reduced with age and parity
- Secondary: likely to require therapy based on underlying cause

**COMPLICATIONS**
- Primary: anxiety and/or depression
- Secondary: infertility from underlying pathology

**REFERENCES**

- Dyspareunia; Endometriosis; Menorrhagia (Heavy Menstrual Bleeding); Premenstrual Syndrome (PMS) and Premenstrual Dysphoric Disorder (PMDD)
- Algorithm: Pelvic Pain

CODES

ICD10

- N94.6 Dysmenorrhea, unspecified
- N94.4 Primary dysmenorrhea
- N94.5 Secondary dysmenorrhea

CLINICAL PEARLS

- Dysmenorrhea is a leading cause of absenteeism for women age <30 years.
- In women who desire contraception, hormonal contraceptives are the preferred treatment.
- All NSAIDs studied have been found to be equally effective in the relief of dysmenorrhea and should be initiated 1 to 2 days prior to onset of menses with scheduled dosing.
DYSPAREUNIA
Scott T. Henderson, MD

BASICS

DESCRIPTION
- Recurrent and persistent genital pain associated with sexual activity, which is not exclusively due to lack of lubrication or vaginismus, and is associated with distress or interpersonal difficulty
- May be the result of organic, emotional, or psychogenic causes
  - Primary: present throughout one’s sexual history
    - Potential relationship exists between primary dyspareunia and vaginismus, low libido, and arousal disorders.
  - Secondary: arising from some specific event or condition (e.g., menopause, drugs)
  - Superficial: pain at, or near, the introitus or vaginal barrel associated with penetration
  - Deep: pain after penetration located at the cervix or lower abdominal area
  - Complete: present under all circumstances
  - Situational: occurring selectively with specific situations
- System(s) affected: reproductive

EPIDEMIOLOGY
- Predominant age: all ages
- Predominant sex: female > male

Incidence
>50% of all sexually active women will report dyspareunia at some time.

Geriatric Considerations
Incidence increases dramatically in postmenopausal women primarily because of vaginal atrophy.

Prevalence
Most sexually active women will experience dyspareunia at some time in their lives.
- ~15% (4–40%) of adult women will have dyspareunia on a few occasions during a year.
- ~1–2% of women will have painful intercourse on a more-than-occasional basis.
- Male prevalence is ~1%.

ETIOLOGY AND PATHOPHYSIOLOGY
- Disorders of vaginal outlet
  - Adhesions
  - Condyloma
  - Clitoral irritation
  - Episiotomy scars
  - Fissures
  - Hymenal ring abnormalities
  - Inadequate lubrication
– Infections
– Lichen planus
– Lichen sclerosus
– Postmenopausal atrophy
– Psoriasis
– Trauma
– Vulvar papillomatosis
– Vulvar vestibulitis/vulvodynia

● Disorders of vagina
  – Abnormality of vault owing to surgery or radiation
  – Congenital malformations
  – Inadequate lubrication
  – Infections
  – Inflammatory or allergic response to foreign substance
  – Masses or tumors
  – Pelvic relaxation resulting in rectocele, uterine prolapse, or cystocele

● Disorders of pelvic structures
  – Endometriosis
  – Levator ani myalgia/spasm
  – Malignant or benign tumors of the uterus
  – Ovarian pathology
  – Pelvic adhesions
  – Pelvic inflammatory disease (PID)
  – Pelvic venous congestion
  – Prior pelvic fracture
  – Uterine fibroids

● Disorders of the GI tract
  – Constipation
  – Crohn disease
  – Diverticular disease
  – Fistulas
  – Hemorrhoids
  – Inflammatory bowel disease

● Disorders of the urinary tract
  – Interstitial cystitis
  – Ureteral or vesical lesions
  – Urethritis

● Chronic disease
  – Behçet syndrome
  – Diabetes
  – Sjögren syndrome

● Male
  – Cancer of penis
  – Genital muscle spasm
  – Infection or irritation of penile skin
  – Infection of seminal vesicles
– Lichen sclerosus
– Musculoskeletal disorders of pelvis and lower back
– Penile anatomy disorders
– Phimosis
– Prostate infections and enlargement
– Testicular disease
– Torsion of spermatic cord
– Urethritis

• Psychological disorders
  – Anxiety
  – Conversion reactions
  – Depression
  – Fear
  – Hostility toward partner
  – Phobic reactions
  – Psychological trauma

RISK FACTORS
• Fatigue
• Stress
• Depression
• Diabetes
• Estrogen deficiency
  – Menopause
  – Lactation
• Previous PID
• Vaginal surgery
• Alcohol/marijuana consumption
• Medication side effects (antihistamines, tamoxifen, bromocriptine, low-estrogen oral contraceptives, SSRIs, depo-medroxyprogesterone, desipramine)

Pregnancy Considerations
• Pregnancy has a potent influence on sexuality; dyspareunia is common in late pregnancy and postpartum.
  – Breastfeeding, perineal pain, fatigue, and stress can be risk factors in postpartum period.
• Episiotomies do not have a protective effect.
  – Women who experience delivery interventions including episiotomy are at greater risk than women who deliver over an intact perineum or have an unsutured tear.

COMMONLY ASSOCIATED CONDITIONS
Vaginismus

DIAGNOSIS

HISTORY
• Identify pain characteristics:
  – Onset
– Duration
– Location: entry versus deep, single versus multiple sites; positional
– Intensity/quality: varying degrees of pelvic/genital pressure, aching, tearing, and/or burning
– Pattern (precipitating or aggravating factors): when pain occurs (at entry, during, or after intercourse)
– Relief measures: Avoid intercourse, change positions, and have intercourse only at certain times of the month.

● Include menstrual, obstetric, reproductive, sexual, domestic violence, and sexual assault histories with past medical, surgical, and psychosocial history.

PHYSICAL EXAM
● A complete exam, including a focused pelvic exam, to identify pathology
  – Exam must include inspection and palpation of urethra, vulva, and vaginal areas; palpation of the uterine, bladder, and adnexal structures; and a rectovaginal exam.
  – Sensory mapping with a cotton-tipped applicator to identify sensitive and painful areas
● Because examination often reproduces the pain, examiner should be cautious and sensitive to patient’s anxiety.

DIFFERENTIAL DIAGNOSIS
Vaginismus (genito-pelvic pain penetration disorder)
● If pain prevents penetration, severe vaginismus may be present.

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
Based on history and exam findings
● Wet mount
● Gonorrhea and chlamydia cultures
● Herpes culture
● Urinalysis and urine culture
● Pap smear

Follow-Up Tests & Special Considerations
● Serum estradiol if vulvodynia or atrophic vaginitis
● Voiding cystourethrogram if urinary tract involvement
● GI contrast studies if GI symptoms
● Ultrasound and CT scan are of limited value; perform if clinically indicated.

Diagnostic Procedures/Other
Based on history and exam findings
● Colposcopy and biopsy if vaginal/vulvar lesions
● Laparoscopy if complex deep-penetration pain
● Cystoscopy if urinary tract involvement
● Endoscopy if GI involvement

Test Interpretation
Depends on etiology
TREATMENT

GENERAL MEASURES

- Educate the patient and partner regarding the nature of the problem. Reassure both that there are solutions to the problem.
- Initiate specific treatment when initial evaluation identifies an organic cause.
- Once organic causes are ruled out, treatment is a multidimensional and multidisciplinary approach; medications alone don’t resolve \( (1) \)[A].
  - Individual behavioral therapy
    - Indicated to help the patient deal with intrapersonal issues and assess the role of the partner
  - Couple behavioral therapy
    - Indicated to help resolve interpersonal problems
    - May involve short-term structured intervention or sexual counseling
    - Designed to desensitize systemically uncomfortable sexual responses and intercourse through a series of interventions over a period of weeks
    - Interventions range from muscle relaxation and mutual body massage to sexual fantasies and erotic massage.

MEDICATION

First Line

- Depends on the etiology
- Antibiotics, antifungals, or antivirals, as indicated, for infection
- Vaginal moisturizers and lubricants for dryness
- Analgesics and topical anesthetics for pain
- Topical/vaginal estrogen for vaginal and vulvar atrophy
  - Available data support the use of estrogen over other vaginal therapies for postmenopausal vaginal symptoms \( (2) \)[A], although vaginal lubricants have an important role in management of atrophy-associated symptoms and may be tried first.
- Neuropathic pain associated with vulvar vestibulitis/vulvodynia may respond to tricyclic antidepressants (amitriptyline or nortriptyline) or gabapentin.

Second Line

- Ospemifene for moderate to severe symptoms due to menopause-related vulvovaginal atrophy \( (3) \)[C]
- TX-004HR estradiol vaginal inserts for the treatment of moderate-to-severe dyspareunia, a symptom of vulvovaginal atrophy due to menopause \( (4) \)[A]
- Intravaginal DHEA (prasterone) for moderate to severe symptoms due to menopause-related vulvovaginal atrophy

ISSUES FOR REFERRAL

Referral for long-term therapy may be necessary.

ADDITIONAL THERAPIES

Physical therapy for pelvic floor muscle pain

SURGERY/OTHER PROCEDURES
Consideration of surgical interventions for dyspareunia due to altered anatomy, uterine position, fibroids, or prior pelvic surgery
- Laparoscopic excision of endometriotic lesions or pelvic adhesions
- Surgical vestibulectomy can be considered if medical measures fail with vulvar vestibulitis.
- Fractional CO$_2$ laser treatments demonstrate improvement in symptoms of vulvovaginal atrophy.
- FDA warns against the use of medical devices for unapproved uses including “vaginal rejuvenation” procedures.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Sitz baths may relieve painful inflammation.
- Perineal massage
- Antioxidants may improve symptoms associated with endometriosis.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Outpatient follow-up depends on therapy.
- Every 6 to 12 months once resolved

DIET
A high-fiber diet may help if constipation is a contributing cause.

PATIENT EDUCATION
- Kegel exercise information
- Provide couples with information about sexual arousal techniques.

PROGNOSIS
Depends on underlying cause but most patients will respond to treatment

REFERENCES

ADDITIONAL READING

SEE ALSO

- Balanitis, Phimosis, and Paraphimosis; Endometriosis; Genito-Pelvic Pain/Penetration Disorder (Vaginismus); Pelvic Inflammatory Disease; Sexual Dysfunction in Women; Vulvovaginitis, Estrogen Deficient; Vulvovaginitis, Prepubescent
- Algorithms: Discharge, Vaginal; Dyspareunia

CODES

ICD10

- N94.1 Dyspareunia
- F52.6 Dyspareunia not due to a substance or known physiol cond

CLINICAL PEARLS

- Careful history to determine if patient feels pain before, during, or after intercourse will help identify cause.
  - Pain before intercourse suggests a phobic attitude toward penetration and/or the presence of vestibulitis.
  - Pain during intercourse combined with the location of the pain is most predictive of the causes of pain.
  - Introital pain after intercourse suggests vestibulitis in women of childbearing age, hypertonic pelvic floor, or vulvovaginal dystrophia.
  - A sudden symptom onset can suggest a psychosexual etiology, whereas gradual onset of symptoms is more likely physical or anatomical.
- Potential relationship exists between primary dyspareunia and vaginismus, low libido, and arousal disorders.
- Episiotomy does not offer any benefit in the prevention of dyspareunia; an episiotomy in fact may cause more future discomfort.
DYSPEPSIA, FUNCTIONAL

Briana Lindberg, MD ● Kristina Burgers, MD, FAAFP

BASICS

DESCRIPTION

- The presence of bothersome postprandial fullness, early satiety, or epigastric pain/burning in the absence of causative structural disease (to include normal upper endoscopy) for at least 1 to 3 days per week for the preceding 3 months, with initial symptom onset at least 6 months prior to diagnosis (Rome IV criteria)
- Rome IV criteria divide patients into two subtypes:
  - Postprandial distress syndrome (PDS)
  - Epigastric pain syndrome (EPS)
- System(s) affected: GI
- Synonym(s): idiopathic dyspepsia; nonulcer dyspepsia; nonorganic dyspepsia; PDS; and EPS

EPIDEMIOLOGY

Incidence
Unknown; accounts for 70% of patients with dyspepsia and ~5% of primary care visits

Prevalence
- 10% prevalence worldwide (varies based on criteria)
- More common in Western cultures
- PDS may be more common in Eastern cultures.
- Predominant age: adults (can be seen in children)
- Predominant gender: female > male

ETIOLOGY AND PATHOPHYSIOLOGY

Unknown but proposed mechanisms or associations include gastric motility disorders, visceral pain hypersensitivity, Helicobacter pylori infection, alteration in upper GI microbiome, postinfectious complications, immune activation, inflammation, and gut-brain axis disorders

Genetics
Possible link to G-protein β3 subunit 825 CC genotype, serotonin transport genes, and/or cholecystokinin-A-receptor gene polymorphisms

Geriatric Considerations
Patients age >60 years with new-onset dyspepsia should undergo endoscopy.

Pediatric Considerations
Be alert for family system dysfunction.

Pregnancy Considerations
Pregnancy may exacerbate symptoms.

RISK FACTORS

- Other functional disorders: fibromyalgia, temporomandibular joint pain, chronic fatigue
syndrome

- Anxiety/depression, psychosocial stressors (e.g., divorce, unemployment; history of physical, sexual, or emotional trauma/abuse)
- Smoking
- Female gender

**GENERAL PREVENTION**
Avoid foods and habits known to exacerbate symptoms.

**COMMONLY ASSOCIATED CONDITIONS**
Other functional bowel disorders

**DIAGNOSIS**

**HISTORY**
- Postprandial fullness (1)
- Early satiety (1)
- Epigastric pain (1)
- Epigastric burning (1)
- Symptoms for 3 months (1)
- Alarm features include (2,3,4):
  - Unintended weight loss
  - Progressive dysphagia
  - Odynophagia
  - Persistent vomiting
  - GI bleeding
  - Family history of upper GI cancer
  - Age ≥60 years

**PHYSICAL EXAM**
- Document weight status and vital signs.
- Examine for signs of systemic illness.
  - Murphy sign for cholecystitis
  - Rebound and guarding for ulcer perforation
  - Palpate during muscle contraction to assess for abdominal wall pain.
  - Jaundice
  - Thyromegaly

**DIFFERENTIAL DIAGNOSIS**
- Peptic ulcer disease; gastroesophageal reflux disease
- Cholecystitis; choledochoolithiasis
- Gastric or esophageal cancer; esophageal spasm
- Malabsorption syndromes; celiac disease
- Pancreatic cancer; pancreatitis
- Inflammatory bowel disease; carbohydrate malabsorption; gastroparesis
- Ischemic bowel disease
- Intestinal parasites
Irritable bowel syndrome
Ischemic heart disease
Diabetes mellitus; thyroid disease; connective tissue disorders
Medication effects

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Functional dyspepsia is a diagnosis of exclusion. Order labs based on clinical suspicion (2)[C].
- Test for H. pylori (stool antigen or urea breath test) in areas of high H. pylori prevalence (2), (4)[A].
- CBC (if anemia or infection are suspected)
- Liver-associated enzymes/right upper quadrant ultrasound (if hepatobiliary disease is suspected)
- Pancreatic enzymes (if pancreatic disease is suspected)
- Upper endoscopy for patients age >60 years to rule out malignancy (4)[C]
- Upper endoscopy is unlikely to change outcomes or management (2,5)[C].
- Self-report questionnaires can track symptoms (3)[C].

Diagnostic Procedures/Other
- Esophageal manometry or gastric accommodation studies are rarely needed (3)[C].
- Motility studies are unnecessary, unless gastroparesis is strongly suspected (4)[C].

Test Interpretation
None (by definition, this a functional disorder)

TREATMENT

GENERAL MEASURES
- Reassurance/physician support is helpful (2,3)[C].
- Treatment is based on presumed etiologies.
- Discontinue offending medications (3)[C].
- Routine endoscopy not recommended in dyspeptic patients age <60 years even without alarm features (4)[B].

MEDICATION

First Line
- Treat H. pylori if confirmed on testing (3,4)[A].
- Trial of once daily proton pump inhibitor (PPI) medication (e.g., omeprazole 20 mg PO QD) or H₂ receptor antagonist (e.g., ranitidine 150 mg BID) for up to 8 weeks in patients without alarm symptoms is most effective for patients with EPS (3,4,5)[A].
- Prokinetics have been proposed as first-line agents in PDS, although efficacy data for metoclopramide, 5 to 10 mg PO TID 30 minutes before meals (only agent approved in United States) are limited (5)[C]. Prokinetics should be prescribed at the lowest effective dose to avoid potential side effects (4)[C]. Use with caution in elderly patients due to side effects of tardive dyskinesia and parkinsonian symptoms.
Second Line

- Trial of tricyclic antidepressant (TCA) medication is more helpful for EPS than PDS (e.g., amitriptyline 25 mg PO QD, can up-titrate to 50 mg PO QD), with a NNT of 6 (2,4)[A]. Caution in elderly. There is no benefit to SSRI/SNRI.
- Trazodone 25 mg at bedtime is an alternative (2,5)[A]. Consider buspirone or mirtazapine if no response or if contraindications to TCA (2)[B].
- Gabapentin 300 mg twice daily can be a useful adjunct, particularly for treatment of gastrointestinal pain symptoms (6)[B].

ADDITIONAL THERAPIES

- Stress reduction (2,5)[C]
- Psychotherapy effective in some patients (2)[C], (3,4)[B]
- Patients should be given a positive diagnosis and reassured of benign prognosis (2)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE

Alternative medicine approaches need further study and are not currently recommended (4)[C].
- STW 5 Iberogast® shown to be helpful in some studies (2)[C].
- Probiotics have theoretical benefit but lack consistent trial data to support routine use (2)[C].
- Hypnotherapy may help (3)[B].
- Transcutaneous electroacupuncture may help (3)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Provide ongoing support and reassurance.
- Upper endoscopy if symptoms persist
- Change medications if no difference in symptoms after 4 weeks (3)[C].
- Discontinue medications once symptoms resolve (3)[C].

DIET

- Limited data to support dietary modification
- Consider limiting fatty foods (2,5)[C].
- Avoid foods that exacerbate symptoms: wheat and cow milk proteins, peppers or spices, coffee, tea, and alcohol (2,5)[C].

PATIENT EDUCATION

Reassurance and stress reduction techniques

PROGNOSIS

Long-term/chronic symptoms with symptom-free periods

COMPLICATIONS

Iatrogenic, from evaluation to rule out serious pathology

REFERENCES

ADDITIONAL READING

SEE ALSO

- Irritable Bowel Syndrome
- Algorithm: Dyspepsia

CODES

ICD10
K30 Functional dyspepsia

CLINICAL PEARLS

- Dyspepsia without underlying organic disease is classified as being functional or idiopathic.
- Consider empiric acid suppression therapy as first line for functional dyspepsia.
- Extensive diagnostic testing is not recommended unless alarm symptoms are present.
DYSPHAGIA
Felix B. Chang Cruz, MD, FAAMA, ABIHM • Amee Phan, DO

BASICS
Impaired passage of the alimentary bolus from the mouth to stomach

DESCRIPTION
- Oropharyngeal: difficulty transferring food bolus from oropharynx to proximal esophagus
- Esophageal: difficulty moving food bolus through the body of the esophagus to the pylorus

EPIDEMIOLOGY
5–8% of the general population >50 years of age

Incidence
Esophageal food impaction 25 per 100,000 persons per year

Prevalence
- From 14% to 33% among community-dwelling individuals 65 years old or older.
- In hospital settings can be as high as 40 percent.
- Nursing home residents range from 29% to 32%.

ETIOLOGY AND PATHOPHYSIOLOGY
- Oropharyngeal (transfer dysphagia):
  - Functional due to disordered motor function in the oropharynx
  - Mechanical causes: Pharyngeal and laryngeal cancer, acute epiglottitis, carotid body tumor, pharyngitis, tonsillitis, strep throat, lymphoid hyperplasia of lingual tonsil, lateral pharyngeal pouch, hypopharyngeal diverticulum
  - Neuromyogenic: Stroke, head trauma, Parkinson and parkinsonism, amyotrophic lateral sclerosis, myasthenia, myopathies (polymyositis, dermatomyositis, muscular dystrophies), alcoholic, thyrotoxicosis, hypothyroidism, amyloidosis, Cushing syndrome
- Esophageal:
  - Mechanical: Carcinomas, esophageal diverticula, esophageal webs, Schatzki ring, structures (peptic, chemical, trauma, radiation), foreign body
  - Extrinsic mechanical lesions: Peritonsillar abscess, thyroid disorders, tumors, mediastinal compression, vascular compression (enlarged left atrium, aberrant subclavius, aortic aneurysm), osteoarthritis of the cervical spine, adenopathy, esophageal duplication cyst
- Infection: Diphtheria, chronic meningitis, tertiary syphilis, Lyme disease, rabies, poliomyelitis, cytomegalovirus, esophagitis (Candida, herpetic)

RISK FACTORS
Children: hereditary and/or congenital malformations
Adults: age >50 years; elderly: gastroesophageal reflux disease (GERD), stroke, chronic obstructive pulmonary disease, chronic pain
Smoking, excess alcohol intake, obesity
Medications: quinine, potassium chloride, vitamin C, tetracycline, Bactrim, clindamycin, nonsteroidal anti-inflammatory drugs, procainamide, anticholinergics, bisphosphonates, anticonvulsants such as phenobarbital, carbamazepine and phenytoin; antidepressants, antihistamines, neuroleptics
Xerostomia is reported with angiotensin-converting enzyme (ACE) inhibitors, antiarrhythmics, antiemetics, diuretics, selective serotonin reuptake inhibitor.
Mucositis by cytotoxic chemotherapy, and molecular target treatment as sunitinib, everolimus
Neurologic events or diseases: CVA, myasthenia gravis, multiple sclerosis, Parkinson disease, amyotrophic lateral sclerosis (ALS), Huntington chorea, dementia
HIV patients with CD4 cell count <100 cells/mm$^3$
Trauma or irradiation of head, neck, and chest; mechanical lesions
Extrinsic mechanical lesions: lung, thyroid tumors, lymphoma, metastasis
Iron deficiency
Anterior cervical spine surgery (up to 71% in the first 2 weeks postop; 12–14% at 1 year postop)
Dysphagia lusoria (vascular abnormalities causing dysphagia): complete vascular ring, double aortic arch, right aortic arch with retroesophageal left subclavian artery and left ligamentum arteriosum, and right aortic arch with mirror-image branching and left ligamentum arteriosum

GENERAL PREVENTION
Correct poorly fitting dentures.
Educate patients to prolong chewing and drink adequate volumes of water at meals.
Liquid and soft food diet as appropriate
Avoid alcohol with meals.
Prophylactic swallowing exercises in patients with head and neck cancer undergoing chemoradiation

COMMONLY ASSOCIATED CONDITIONS
Peptic structure, esophageal webs and rings, carcinoma, history of stroke, dementia, pneumonia

DIAGNOSIS
HISTORY
Dysphagia to both solids and liquids from the onset of deglutition likely represents an esophageal motility disorder.
Oropharyngeal dysphagia presents as difficulty initiating the swallowing process.
Dysphagia for solids that progresses to involve liquids more likely reflects mechanical obstruction.
Progressive dysphagia is usually caused by cancer or a peptic stricture. Intermittent dysphagia is most often related to a lower esophageal ring.
Inquire about heartburn, weight loss, hematemesis, coffee ground emesis, anemia, regurgitation of undigested food particles, and respiratory symptoms.
Inquire about regurgitation, aspiration, or drooling immediately after swallowing as this may represent oropharyngeal dysphagia.

Does the food bolus feel stuck?
– Upper sternum or back of throat may represent oropharyngeal dysphagia, whereas sensation over the lower sternum is typical of esophageal dysphagia.

Is odynophagia present?
– May represent inflammation, achalasia, diffuse esophageal spasm, esophagitis, pharyngitis, pill-induced esophagitis, cancer

Globus sensation (“lump in the throat”)?
– Potentially indicates cricopharyngeal or laryngeal disorders

History of sour taste in the back of the throat or chronic heartburn suggests GERD.

Inquire about alcohol and/or tobacco use.

Are there associated symptoms such as weight loss or chest pain?
– Double aortic arch, right aortic arch with retroesophageal left subclavian artery and left ligamentum arteriosum
– Anticholinergics, antihistamines, and some antihypertensives can decrease salivary production.

Halitosis: Rule out diverticulitis.

Prior history of a connective tissue disorder

Changes in speech, hoarseness, weak cough, dysphonia? Rule out neuromuscular dysfunction.

PHYSICAL EXAM

Skin: telangiectasia, sclerodactyly, calcinosis (r/o autoimmune disease); Raynaud phenomenon, sclerodactyly may be found in CREST syndrome or systemic scleroderma; stigmata of alcohol abuse (palmar erythema; telangiectasia)

Head, eye, ear, nose, throat (HEENT):
– Oropharyngeal: pharyngeal erythema/edema, tonsillitis, pharyngeal ulcers or thrush, odynophagia (bacterial, viral, fungal infections); tongue fasciculations (ALS)
– Neck: masses, lymphadenopathy, neck tenderness (thyroiditis), goiter

Neurologic:
– Cranial nerve exam: sensory: cranial nerves V, IX, and X; motor: cranial nerves V, VII, X, XI, and XII
– Central nervous system, mental status exam, strength testing, Horner syndrome, ataxia, cogwheel rigidity (CVA, dementia, Parkinson disease, Alzheimer disease)
  – Eye position, extraocular motility

Informal bedside swallowing evaluation: Observe level of consciousness, postural control—upright position, oral hygiene, mobilization of oral secretions.

DIFFERENTIAL DIAGNOSIS
See “Etiology and Pathophysiology.”

DIAGNOSTIC TESTS & INTERPRETATION

Adults (1)[C]:
– Barium swallow if endoscopy test fail to identify an abnormality.
– Fiber-optic endoscopic examination of swallowing (FEES)
– Gastroesophageal endoscopy (2)[C]
– Barium cine/video esophagram
Ambulatory 24-hour pH testing if reflux is suspected
- Esophageal manometry if history suggest dysmotility disorder achalasia, diffuse esophageal spasm, scleroderma esophagus, nutcracker esophagus, hypertensive lower esophageal sphincter, ineffective esophageal motility, collagen vascular disease (scleroderma, CREST).
- Videofluoroscopic swallowing study (VFSS): oropharyngeal dysphagia

**Initial Tests (lab, imaging)**
- Guided by diagnostic considerations
  - CBC (infection and inflammation)
  - Serum protein and albumin levels for nutritional assessment
  - Thyroid function studies to detect dysphagia associated with hypothyroidism or hyperthyroidism, cobalamin levels
  - Antiacetylcholine antibodies (myasthenia)
- Barium swallow: detects strictures or stenosis; if endoscopy fails to identify an abnormality

**Follow-Up Tests & Special Considerations**
- CT scan of chest; MRI of brain and cervical spine
- VFSS (lips, tongue, palate, pharynx, larynx, proximal esophagus)
- Fiber-optic endoscopy and videofluoroscopy are similar in terms of diagnostic sensitivity.

**Diagnostic Procedures/Other**
Endoscopy with biopsy; esophageal manometry; esophageal pH monitoring

---

**TREATMENT**

**GENERAL MEASURES**

**MEDICATION**
Modify medications taken by patient according to patient functional swallowing ability (3)[C].

**First Line**
- For esophageal spasms: calcium channel blockers: nifedipine 10 to 30 mg TID; imipramine 50 mg at bedtime; sildenafil 50 mg/day PRN
- For esophagitis:
  - Antacids (calcium carbonate, magnesium hydroxide, aluminum hydroxide, sodium bicarbonate-based)
  - H2 blockers:
    - Cimetidine: up to 1,600 mg orally per day in 2 or 4 divided doses for 12 weeks
    - Ranitidine: initial 150 mg orally 4 times daily and maintenance 150 mg orally twice daily
    - Nizatidine: 150 mg orally twice daily for 12 weeks
    - Famotidine: 20 to 40 mg orally twice daily for 12 weeks
- Proton pump inhibitors:
  - Omeprazole: 20 mg once daily for 4 to 8 weeks
  - Lansoprazole: 30 mg once daily for up to 8 weeks
  - Rabeprazole: 20 mg orally once daily for 4 to 8 weeks
– Esomeprazole: 20 to 40 mg orally once daily for 4 to 8 weeks
– Pantoprazole: 40 mg orally once daily for up to 8 weeks

**ISSUES FOR REFERRAL**
- Gastroenterology: endoscopy, refractory symptoms
- Surgery: dilation, esophageal myotomy, biopsy

**ADDITIONAL THERAPIES**
Speech therapy to assess swallowing; nutritional evaluation and positioning, physical therapy for muscle-strengthening exercise, remaining upright after eating
- Self-expanded metal stent is safe, effective, and quicker in palliating dysphagia compared to other modalities.

**SURGERY/OTHER PROCEDURES**
- Esophageal dilatation (pneumatic or bougie) for achalasia.
- Esophageal stent; laser for cancer palliation
- Treat underlying problem (e.g., thyroid goiter, vascular ring, esophageal atresia).
- Nd:YAG laser incision of lower esophageal rings refractory to dilation
- Photodynamic therapy (cancer)
- Cricopharyngeal myotomy (oropharyngeal dysphagia)
- Surgery for Zenker diverticulum, refractory strictures, or myotomy (for achalasia)
- Percutaneous endoscopic gastrostomy (PEG) decreases risk of dysphagia when compared with nasogastric tube.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Acupuncture does not appear to improve swallowing disability more than sham acupuncture in neurogenic dysphagia
- Insufficient evidence for routine use of botulinum toxin

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Complete or partial esophageal obstruction associated with malnutrition or dehydration
- Need for enteral feeding
- Outpatient if patient is able to maintain nutrition and has little risk of complications
- Hospitalization with total or near-total obstruction of esophageal lumen
- Hospitalization may be needed for endoscopy and/or esophageal dilatation and is generally indicated for diagnostic or therapeutic surgical procedures.
- IV fluids for dehydrated, hypovolemic patients, and patients with impaired consciousness
- Discharge when tolerating adequate diet without nausea/pain

**ONGOING CARE**
Shallow therapy may reduce the incidence of chest infections or pneumonia after stroke. Low quality evidence (4)[A].

**FOLLOW-UP RECOMMENDATIONS**
Soft puree diet may be useful in mechanical esophageal narrowing. In severe or prolonged dysphagia, enteral feeding using nasogastric tube or gastrostomy may be required.
Patient Monitoring
Medications should be reviewed.

DIET
See “General Prevention.”

PATIENT EDUCATION
Safe swallowing (5)[C]:
- Sit upright at 90 degrees and avoid drinking or eating when lying down or slouched.
- Drink using small sips of liquids, without any gulping.
- Eat slowly, small bites of food, chew food completely before swallowing, do not swallow any drink or food before taking more.
- Not use drinks to wash down food.
- Refrain from talking when food is in their mouth.

PROGNOSIS
45% reported mortality within 12 months in nursing home residents with oropharyngeal dysphagia an aspiration.

COMPLICATIONS
- Oropharyngeal: pneumonia, lung abscess, aspiration pneumonia, airway obstruction
- Malnutrition and dehydration, frailty
- Contribute to the development of sarcopenia, reduce immunity, impaired wound healing.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- R13.10 Dysphagia, unspecified
- R13.12 Dysphagia, oropharyngeal phase
- R13.14 Dysphagia, pharyngoesophageal phase

CLINICAL PEARLS
- Acute dysphagia for solids and/or liquids requires immediate attention.
- Dysphagia in older adults should not be simply attributed to normal aging.
- Normal endoscopy does not rule out structural abnormality
ECTOPIC PREGNANCY
Jeremy Golding, MD, FAAFP

BASICS

DESCRIPTION
Ectopic: pregnancy implanted outside the uterine cavity. Subtypes include:
- Tubal: pregnancy implanted in any portion of the fallopian tube
- Abdominal: pregnancy implanted intra-abdominally, most commonly after tubal abortion or rupture of tubal ectopic pregnancy
- Heterotopic: pregnancy implanted intrauterine and a separate pregnancy implanted outside uterine cavity
- Ovarian: implantation of pregnancy in ovarian tissue
- Cervical: implantation of pregnancy in cervix
- Intraligamentary: implantation of pregnancy within the broad ligament

EPIDEMIOLOGY

Incidence
- The true incidence is difficult to estimate. Incidence is likely between about 6 and 20 per 1,000 pregnancies in the United States. About 1 in 10 1st trimester pregnancies presenting to the emergency with pain and/or bleeding are due to ectopic pregnancy.
- In the United States, ectopic pregnancy is the leading cause of 1st trimester maternal deaths.
- Heterotopic pregnancy, although rare (1:30,000), occurs with greater frequency in women undergoing in vitro fertilization (IVF) (1/1,000).
- Increasing incidence of nontubal, and particularly cesarean scar ectopic pregnancies, due in part to more cesarean sections and more IVF

Prevalence
- ~33% recurrence rate if prior ectopic pregnancy

ETIOLOGY AND PATHOPHYSIOLOGY
- 95–97% of ectopic pregnancies occur in the fallopian tube, of which, 55–80% in the ampulla, 12–25% in the isthmus, and 5–17% in the fimbria.
- One risk factor for a tubal pregnancy is impaired movement of the fertilized ovum to the uterine cavity due to dysfunction of the tubal cilia, scarring, or narrowing of the tubal lumen.
- Other locations are rare but may occur from reimplantation of an aborted tubal pregnancy or from uterine structural abnormalities (mainly cervical pregnancy).

RISK FACTORS
- History of pelvic inflammatory disease (PID), endometritis, or current gonorrhea/chlamydia infection
- Previous ectopic pregnancy
- History of tubal surgery (~33% of pregnancies after tubal ligation will be ectopic)
- Pelvic adhesive disease (infection or prior surgery)
- Use of an intrauterine device (IUD): IUD reduces absolute risk of ectopic pregnancy, but there is an increased likelihood of ectopic location if pregnancy occurs.
Use of assisted reproductive technologies
Maternal diethylstilbestrol (DES) exposure in utero (DES was last used in 1972)
Tobacco use
Patients with disorders that affect ciliary motility may be at increased risk (e.g., endometriosis, Kartagener).

GENERAL PREVENTION
● Reliable contraception or abstinence
● Screening for and treatment of STIs (i.e., gonorrhea, chlamydia) that can cause PID and tubal scarring

DIAGNOSIS

HISTORY
In >50% of presenting cases, patients have sudden-onset abdominal pain coupled with cessation of/irregular menses and acute vaginal bleeding (the classic triad). Other common symptoms include nausea and/or vomiting, vaginal bleeding, and pain referred to the shoulder (from hemoperitoneum).

PHYSICAL EXAM
● Abdominal tenderness ± rebound tenderness
● Vaginal bleeding
● Palpable mass on pelvic exam (adnexal or cul-de-sac fullness)
● Cervical motion tenderness
● In cervical cases, an hourglass-shaped cervix might be noted.
● In cases of rupture and significant intraperitoneal bleeding, signs of shock such as pallor, tachycardia, and hypotension may be present.

DIFFERENTIAL DIAGNOSIS
● Missed, threatened, inevitable, or completed abortion (miscarriage)
● Gestational trophoblastic neoplasia (“molar pregnancy”)
● Appendicitis
● Salpingitis, PID
● Ruptured corpus luteum or hemorrhagic cyst
● Ovarian tumor, benign or malignant
● Ovarian torsion
● Cervical polyp, cancer, trauma, or cervicitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
● Check CBC and ABO type and antibody screen.
● Transvaginal US (TVUS) is the gold standard for diagnosis:
  − Failure to visualize a normal intrauterine gestational sac when serum human chorionic gonadotropin (hCG) is above the discriminatory level (>1,500 to 2,000 IU/L) suggests an abnormal pregnancy of unknown location (PUL).
  − An hCG level of 3,500 IU/L is associated with a 99% probability of detecting a normal intrauterine gestational sac in clinical practice (1).
These values are not validated for multiple gestations.

- If TVUS unavailable or inconclusive for intrauterine pregnancy (IUP), check hCG: Serial quantitative serum levels normally increase by at least 53% every 48 hours: Abnormal rise (<35%) should prompt workup for gestational abnormalities. Clinical impression of acute abdomen/intraperitoneal bleeding concurrent with a positive hCG level is indicative of ectopic pregnancy until proven otherwise.
- MRI may also be useful but costly and rarely used if TVUS is available; benefits particularly for abdominal or cesarean scar pregnancy

Follow-Up Tests & Special Considerations

- Serum progesterone level: >20 mg/mL associated with lower risk of ectopic pregnancy. In women with pain and/or bleeding who have an inconclusive US, serum progesterone level <3.2 ng/mL ruled out a viable pregnancy in 99.2% of women (2); may provide additional data for PUL but does not predict ectopic pregnancy (3)[B]
- Under investigation: evaluation of serum progesterone levels in conjunction with vascular endothelial growth factor, inhibin A, and activin A using an algorithm. This diagnosed patients with ectopic pregnancy with 99% accuracy.

Diagnostic Procedures/Other

- In the setting of an undesired pregnancy, sampling of the uterine cavity with endometrial biopsy or D&C can identify the presence/absence of intrauterine chorionic villi. When an IUP has been evacuated by curettage, hCG levels should drop by 50% within 48 hours.
- Historically, culdocentesis was performed to confirm suspected hemoperitoneum prior to surgical management. Currently, TVUS quantification of pelvic fluid is sufficient.

Test Interpretation

Products of conception (POC; especially chorionic villi) outside the uterine cavity

TREATMENT

MEDICATION

- Methotrexate: treatment for unruptured tubal pregnancy or for remaining POCs after laparoscopic salpingostomy. Methotrexate inhibits DNA synthesis via folic acid antagonism by inactivating dihydrofolate reductase.
- If TVUS is suggestive but not diagnostic, in the hemodynamically stable patient who qualifies for medical management, confirm suspected US findings with 2 hCG levels drawn 48 hours apart. Rise <35% is consistent with nonviable pregnancy.
- Most effective when pregnancy is <3 cm diameter, hCG <5,000 mIU/mL, and no fetal heart movement is seen. Success rate is 88% if hCG <1,000 mIU/mL, 71% if hCG 1,000 to 2,000 mIU/mL, 38% if 2,000 to 5,000 mIU/mL:
  - Three main dosage regimens exist (4), but single dose regimen is preferred (X) for simplicity, safety, and comparable effectiveness to multidose regimens (4,5)[A]:
    - Single: IM methotrexate 50 mg/m² of body surface area (BSA); may repeat once if <15% decline in hCG between day 4 and 7. Follow hCG weekly.
    - Double dose: methotrexate 50 mg/m² of BSA once and then repeated on day 4; if <15% decline in hCG between day 4 and 7, may repeat third dose on day 7. Repeat hCG as
needed on days 11 and 14 until decreases >15% in the interval and then weekly. If not dropping by day 14, refer for surgical management.

- Multidose: methotrexate 1 mg/kg IM/IV every other day, with leucovorin 0.1 mg/kg IM in between. Maximum 4 doses until hCG drop below 15%; course may be repeated 7 days after last dose if necessary.

- Contraindications:
  - Hemodynamic instability or any evidence of rupture
  - Moderate to severe anemia
  - Severe hepatic or renal dysfunction
  - Immunodeficiency

- Relative contraindications
  - Fetal heart activity seen
  - Large gestational sac (>3 cm, less effective)
  - Noncompliance or limited access to hospital or transportation
  - hCG >5,000 mIU/Ml

- Precautions: immunologic, hematologic, renal, GI, hepatic, and pulmonary disease, or interacting medications
- Pretreatment testing: serum hCG, CBC, liver and renal function tests, blood type and screen
- Patient counseling: During therapy, refrain from use of alcohol, aspirin, NSAIDs, and folate supplements (decreases efficacy of methotrexate); avoid excessive sun exposure due to risk of sensitivity.
  - Adherence to scheduled follow-up appointments is critical.
  - Increased abdominal pain may occur during treatment; however, severe pain, nausea, vomiting, bleeding, dizziness, or light-headedness may indicate treatment failure and require urgent evaluation.

- Rupture of ectopic pregnancy during methotrexate treatment ranges from 7% to 14%.
- Side effects include stomatitis; conjunctivitis; abdominal cramping; and rarely neutropenia, pneumonitis, or alopecia (5).
- Systemic methotrexate may be offered in some kinds of nontubal ectopic pregnancies, but data is limited.

**ISSUES FOR REFERRAL**

- Consider gynecologic consultation if not experienced in medical management.
- Refer to a gynecologist for surgical care.

**ADDITIONAL THERAPIES**

- Physician or patient may elect for surgical treatment as primary method and then postop hCG should guide need for supplemental methotrexate.
- After evidence of medical failure or tubal rupture, surgery is necessary.
- Treatment of cervical, ovarian, abdominal, or other ectopic pregnancy is complicated and requires immediate specialist referral.
- Follow all patients treated medically to an hCG of 0 to ensure that there is no need for surgical intervention.
- Offer anti-D Rh prophylaxis at a dose of 50 μg to all Rh-negative women who have a surgical procedure to manage an ectopic pregnancy or if there has been significant bleeding or abdominal pain.
- Expectant management of ectopic (confirmed on TVUS) may be offered to women who are
clinically stable and have low and decreasing hCG level initially <1,500 mIU/mL (3)[B].

- Expectant management to allow for spontaneous resolution of PUL is acceptable in asymptomatic patients with no evidence of rupture or hemodynamic instability coupled with an appropriately low hCG and no extrauterine mass suggestive of ectopic. Ruptured tubal pregnancies may occur even with extremely low hCG levels (<100 mIU/mL) (6).
- With expectant management of PUL, repeat TVUS weekly (or when hCG above discriminatory zone) until location is confirmed or clinical picture is unstable.

SURGERY/OTHER PROCEDURES
- Indications include ruptured ectopic pregnancy, inability to comply with medical follow-up, previous tubal ligation, known tubal disease, current heterotopic pregnancy, desire for permanent sterilization at time of diagnosis.
- Laparoscopy is the first-line surgical management (3)[A].
- Salpingectomy (tubal removal) is preferred and is indicated for uncontrolled bleeding, recurrent ectopic pregnancy, severely damaged tube, large gestational sac, or patient’s desire for sterilization (3)[B].
- Salpingostomy (preservation of tube) is considered in patients who wish to maintain fertility particularly if contralateral tube is damaged/absent (3)[C]:
  - No difference in recurrence rate compared to salpingectomy
  - Persistent trophoblastic tissue with salpingostomy remains in the fallopian tube in 4–15% of cases; will need to follow weekly hCG
- Use of US-guided intra-amniotic injection with methotrexate and/or potassium chloride is experimental at this time.
- Surgical treatment is first line for cesarean and cornual pregnancies.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Fails criteria for methotrexate management, suspicion of rupture, orthostatic, shock, and severe abdominal pain requiring IV narcotics
- Inpatient observation in the setting of an uncertain diagnosis, particularly with an unreliable patient, may be appropriate.
- Surgical emergency
  - Two IV access lines should be placed immediately if suspicion of rupture; aggressive resuscitation as needed
  - Blood product transfusion if necessary en route to OR
  - In cases of shock, pressors and cardiac support may be necessary.
- IV fluids
  - Unnecessary for a stable ectopic pregnancy being medically treated
  - Critical for a surgical patient who is bleeding
- Strict input/output, hourly vitals, orthostatics if mobile, frequent abdominal exams, serial hematocrit, pad counts if heavy vaginal bleeding
- Discharge criteria: afebrile, abdominal pain resolving or resolved, diagnosis established, surgical treatment, and recovery is complete

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
**Patient Monitoring**
- Serial serum quantitative hCG until level drops to zero:
  - After methotrexate administration, a strict monitoring protocol should be followed.
  - Following salpingostomy, weekly levels are appropriate.
  - Following salpingectomy, further follow-up may be unnecessary.
- Pelvic US for persistent or recurrent masses
- Pain control: brief course of narcotics usually necessary with medical or surgical management
- Liver and renal function tests weekly following methotrexate administration if repeat dosing is required
- Delay of subsequent pregnancy for at least 3 months after treatment with methotrexate due to teratogenicity (folate deficiency) (3)[C]

**Diet**
- During treatment, avoid alcohol and foods and vitamins high in folate (leafy greens, liver, edamame) due to interaction with methotrexate efficacy.
- Maintain excellent hydration.

**Patient Education**
- Signs and symptoms of ectopic pregnancy should be reviewed.
- Patients should be encouraged to plan subsequent pregnancies and seek early medical care on discovery of future pregnancies.

**Prognosis**
- Chronic ectopic pregnancies are rare and treated with surgical removal of the fallopian tube.
- Future fertility depends on fertility prior to ectopic pregnancy and degree of tubal compromise. In women with normal fertility, treatment options have no differences in future fertility rates. In women with subfertility, expectant or medical treatments confer better future fertility (3) [C].
- ~66% of women with a history of ectopic pregnancy will have a future IUP if they are able to conceive.
- If infertility persists beyond 12 months, the fallopian tubes should be evaluated.

**Complications**
- Hemorrhage and hypovolemic shock
- Persistent trophoblastic tissue after medical or surgical management
- Infection
- Infertility
- Blood transfusions with associated infections/transfusion reaction
- Disseminated intravascular coagulation in the setting of massive hemorrhage

**References**

ADDITIONAL READING

CODES
ICD10
● O00.9 Ectopic pregnancy, unspecified
● O00.1 Tubal pregnancy
● O00.0 Abdominal pregnancy

CLINICAL PEARLS
● Ectopic pregnancy is the leading cause of 1st trimester maternal death and accounts for 6% of U.S. pregnancy deaths.
● 97% of ectopic pregnancies occur in the fallopian tube.
● Diagnosis requires high clinical suspicion in the setting of abdominal pain and a positive pregnancy test until IUP is confirmed.
**EJACULATORY DISORDERS**
Payam Sazegar, MD, CCFP

---

**BASICS**

**DESCRIPTION**

- Group of dysfunctions involving altered time and control (premature ejaculation [PE], delayed ejaculation [DE]), presence (anejaculation [AE]), direction (retrograde ejaculation [RE]), volume (perceived ejaculate volume reduction [PEVR]), or force (decreased force of ejaculation [DFE]) of ejaculation

- **PE** is defined (DSM-V, 2013) as a persistent/recurrent pattern of ejaculation occurring during partnered sexual activity within 1 minute following vaginal penetration and before the individual wishes it + present for 6 months + causing significant distress for individual.
  - Natural biologic response is to ejaculate within 2 to 5 minutes after vaginal penetration.
  - Ejaculatory control is an acquired behavior that increases with experience.
  - Comorbidities common (diabetes, hypertension, sexual desire disorder, ED)

- **DE**: prolonged time to ejaculate (>30 minutes) despite desire, stimulation, and erection; problematic for couples trying to conceive

- **Aspermia** (lack of sperm in the ejaculate):
  - **AE**: lack of emission or contractions of bulbospongiousus muscle
  - **RE**: partial or complete ejaculation of semen into the bladder
  - Obstruction: ejaculatory duct obstruction or urethral obstruction

- **Also**:
  - Painful ejaculation: genital or perineal pain during or after ejaculation
  - Ejaculatory anhedonia: normal ejaculation lacking orgasm or pleasure
  - Hematospermia: presence of blood in the ejaculate (often not a serious condition)

**EPIDEMIOLOGY**

**Prevalence**

- **PE** is common; reported prevalence in U.S. males in up to 20–30%.
- **DE** is reported in 5–8% of men age 18 to 59 years, but <3% have the problem for >6 months.
- Predominant age: all sexually mature age groups
- Predominant sex: male only

**ETIOLOGY AND PATHOPHYSIOLOGY**

**Male sexual response**:

- Erection mediated by parasympathetic nervous system

- Normal ejaculation consists of three phases:
  - Emission phase: semen is deposited into urethra by contraction of prostate, seminal vesicles, vas deferens; under autonomic sympathetic control
  - Ejaculation phase: semen forcibly propelled out of urethra by rhythmic contractions of the bulbospongiousus and ischiocavernosus muscles. This is mediated by the somatic nervous system on the motor branches of the pudendal nerve. Bladder neck contracture by α-adrenergic receptors ensures anterograde ejaculation.
  - Orgasm: the pleasurable sensation associated with ejaculation (cerebral cortex); smooth
muscle contraction of accessory sexual organs; release of pressure in posterior urethra

- **PE:**
  - Hypersensitivity/hyperexcitability of glans penis
  - 5-hydroxytryptamine (5-HT) receptor sensitivity
  - Psychogenic (inexperience, anxiety/guilt, low frequency of sex, relationship problems)
  - Urologic (ED, prostatitis, urethritis)
  - Endocrine (hyperthyroid)
  - Lack of physical or sexual activity
  - Withdrawal/detox of prescription or illicit drugs

- **DE:**
  - Rarely due to underlying painful disorder (e.g., prostatitis, seminal vesiculitis)
  - Often has psychogenic component
  - No relation to testosterone levels
  - Sexual performance anxiety and other psychosocial factors
  - Medications may impair ejaculation (e.g., MAOIs, SSRIs, α- and β-blockers, thiazides, antipsychotics, tricyclic and quadricyclic antidepressants, NSAIDs, opiates, alcohol).

- **Never any ejaculate:**
  - Congenital structural disorder (müllerian duct cyst, Wolffian abnormality)
  - Acquired (radical prostatectomy, postinfectious, posttraumatic, T10–T12 neuropathy)

- **AE:**
  - Retroperitoneal lymph node (LN) dissection
  - Spinal cord injury or other (traumatic) sympathetic nerve injury
  - Medications (α- and β-blockers, benzodiazepines, SSRIs, MAOIs, TCAs, antipsychotics, aminocaproic acid)
  - Diabetes mellitus (DM) (neuropathy)
  - Radical prostatectomy

- **RE:**
  - Transurethral resection of the prostate (25%) or other prostate resection procedures
  - Surgery on the neck of the bladder
  - Extensive pelvic surgery
  - Retroperitoneal LN dissection for testicular cancer (also may produce failure of emission)
  - Neurologic disorders (MS, DM)
  - Medications (tamsulosin, other α-blockers, SSRIs, antipsychotics)
  - Urethral stricture (may be posttraumatic)

- **Painful ejaculation:**
  - Infection or inflammation (orchitis, epididymitis, prostatitis, urethritis)
  - Ejaculatory duct obstruction
  - Seminal vesicle calculi
  - Obstruction of the vas deferens
  - Psychological/functional

- **Hematospermia (often unable to find cause):**
  - Usually not a serious condition
  - Inflammation/infection
  - Calculi: bladder, seminal vesicle, prostate, urethra
  - Trauma to genital area (cycling, constipation, masturbation)
  - Obstruction
– Cyst
– Tumor (1–3% prostate cancers present with hematospermia)
– Arteriovenous malformations
– Iatrogenic
– Hypertension

COMMONLY ASSOCIATED CONDITIONS
● Neurologic disorders (e.g., multiple sclerosis)
● Diabetes
● Prostatitis
● Ejaculatory duct obstruction
● Urethral stricture
● Psychological disorders
● Endocrinopathies
● Relationship/interpersonal difficulties

DIAGNOSIS
Based on a good history. Start by asking if ejaculation occurs before individual wishes OR does not occur following normal stimulation (including masturbation).

HISTORY
Detailed sexual history, including:
● Time frame of the problem
● Quality of patient’s sexual response
● Sense of ejaculatory control and sexual distress
● Overall assessment of the relationship
● Ask specific questions because patients often reluctant to discuss openly.
● Detailed history of recent and current medications
● History of past trauma or recent infections
● Past surgical history with particular attention to genitourinary (GU) surgeries
● Supplements and alternative therapies tried
● Many men do not distinguish initially between problems related to erection and ejaculation.
● Some men have unrealistic expectations of ejaculatory response and frequency.
● Include the sexual partner in the interview, especially if the patient expresses a belief that he is not meeting his partner’s needs.
● In review of systems, elicit any evidence of testosterone deficiency or prolactin excess, especially if anhedonia present.

PHYSICAL EXAM
● Check vitals. Look for focal neurologic signs (MS, spinal cord injury) and psychiatric disorders.
● Thorough GU exam, including:
  – Size and texture of testes and epididymis
  – Verification of the presence of the vas deferens
  – Location and patency of urethral meatus
  – Digital rectal examination to evaluate prostate consistency, size, and possible midline
lesions

**DIAGNOSTIC TESTS & INTERPRETATION**

- Laboratory test results may be normal.
- Fasting glucose or HgbA1c to rule out diabetes.
- Postorgasmic urinalysis will confirm RE. Semen fructose level, sperm count, and viscosity can be measured. Patient may complain of cloudy urine.
- AE will have fructose negative, sperm negative, and nonviscous postorgasmic urinalysis.
- In painful ejaculation, urinalysis and urine culture needed to rule out infection.
- If prostate cancer is considered, check prostate-specific antigen (PSA).
- In anhedonia, consider checking testosterone, prolactin, glucose, and thyroid levels.
- In hematospermia, painful ejaculation, or if ejaculatory duct obstruction is considered, transrectal ultrasound (TRUS) may be helpful.
- TRUS-guided seminal vesicle aspiration if ejaculatory duct obstruction is present.
- If suspicious of anatomic abnormality, can get scrotal US and/or MRI.

---

**TREATMENT**

**GENERAL MEASURES**

- Identifying any medical cause (even if not reversible) helps patient accept condition.
- Improve partner communication.
- Psychological counseling for patient and partner.
- Reduce performance pressure through reassurance.
- Use of a variety of resources may be necessary (e.g., psychiatrist, psychologist, sex therapist, vascular surgeon, urologist, endocrinologist, neurologist).

PE:
- Use sensate focus therapy (gradual progression of nonsexual contact to sexual contact).
- Quiet vagina: Female partner stops moving just prior to ejaculation.
- Techniques to learn ejaculatory control (e.g., coronal squeeze technique [squeezing the glans penis until ejaculatory urge ceases] or start-and-stop technique [cessation of penile stimulation when ejaculation approaches and resumption of stimulation when ejaculatory feeling ends]) (1)[B]

DE:
- Change to antidepressant less likely to cause DE (citalopram, fluvoxamine, nefazodone) (2)[B]

AE/RE:
- Discontinue offending medications.
- Diabetic control.
- If urethral obstruction present, refer to urology.
- RE may be helped if intercourse occurs when bladder is full.
- Consider penile vibratory stimulation (effective in spinal cord injuries >T10) or electroejaculation (place on monitor if lesions above T6 because autonomic dysreflexia may result) to collect sperm in AE cases.

Painful ejaculation:
- Counseling may be beneficial.
- If seminal vesicle stones are possible, refer to urology.
Hematospermia:
- Often resolves spontaneously, without known cause. Reassure initially.
- May try empiric antibiotic, but little evidence to support.
- If persistent or high degree of suspicion for abnormality, refer to urologist.

**MEDICATION**

**PE:**
- Treat underlying erectile dysfunction (a common comorbidity) with PDE5 inhibitors (3)[A].
- First line:
  - Dapoxetine, a short-acting SSRI, used “on demand” 30 to 60 mg 1 to 2 hours prior to sex has good efficacy (2,3,4)[A]; best efficacy but higher cost.
  - Other “on-demand” options include clomipramine 20 to 50 mg 4 to 24 hours before intercourse, sertraline 50 mg 4 to 8 hours before intercourse, and paroxetine 20 mg 3 to 4 hours before intercourse (2,3,4)[A].
  - Daily dosing of clomipramine 20 to 50 mg, sertraline 25 to 200 mg, fluoxetine 5 to 20 mg, or paroxetine 10 to 40 mg can delay ejaculation within 1 to 3 weeks of starting (2,3)[A].
  - PDE5 inhibitor with or without SSRI (3)[A]
  - Topical anesthetic gel applied (2.5% prilocaine ± 2.5% lidocaine [EMLA]) 2.5 g under a condom for 30 minutes prior to intercourse (5)[A]
  - Tramadol 5 to 50 mg used “on demand” 2 hours before sex. Effective in many studies (6)[A]; now available in spray form
  - Second line: behavioral/sex therapy, pelvic floor muscle therapy (1,2)[B]

**DE:**
- No “approved” drugs; many options
- Consider switching antidepressants to bupropion, nefazodone, and mirtazapine.
- Patients who must continue SSRIs may respond to bupropion and buspirone (2,7)[B].
- Sex therapy, self-stimulation therapies (1,2)[B]
- Some evidence that amantadine or cyproheptadine may be helpful (2,7)[B]

**AE and RE:**
- First line: pseudoephedrine 60 mg PO daily to QID or imipramine 25 to 75 mg PO BID (8)[A]
- α-Agonists and antihistamines can be helpful but are not approved by the FDA.
- Second line: for RE, can try postejaculation bladder harvest of sperm (if fertility desired); for AE, can try midodrine, penile vibratory stimulation, or electroejaculation (2,8)[B]

**Painful ejaculation:**
- Treat underlying infection/inflammatory process.
- α-Blockers may have some benefit.

**ISSUES FOR REFERRAL**
The following conditions, when suspected, should be referred to a urologist:
- Ejaculatory duct obstruction
- Seminal vesicle or prostatic stones
- Urethral obstruction
- Vas deferens obstruction
- Calculi
- Persistent or severe hematospermia (2)[B]
SURGERY/OTHER PROCEDURES
Surgical treatment of ejaculatory duct obstruction:
- Transurethral resection of the ejaculatory ducts

ONGOING CARE

PATIENT EDUCATION
See “General Measures.”

PROGNOSIS
Often improves with therapy and counseling

COMPLICATIONS
Psychological impact on some males: signs of severe inadequacy, self-doubt, additional anxiety, and guilt

REFERENCES

ADDITIONAL READING
CODES

ICD10
- F52.4 Premature ejaculation
- N53.11 Retarded ejaculation
- N53.14 Retrograde ejaculation

CLINICAL PEARLS
- If erectile dysfunction is contributing to ejaculatory difficulty, management of erectile dysfunction should precede attempted management of ejaculatory disorders.
- Medications should always be thoroughly reviewed because they may be the primary cause of ejaculatory disorders.
- PE and DE generally have both psychogenic and physical causes, whereas AE and RE are due to organic neurogenic/autonomic dysfunction.
- A multidisciplinary approach, including the primary care physician, urologists, psychologists, and other appropriate health care professionals, is essential to the proper treatment of ejaculatory disorders.
ELDER ABUSE
Nitin Budhwar, MD

BASICS

DESCRIPTION
- The National Center of Elder Abuse divides abuse into three categories (age >60) (1):
  - **Domestic**: abuse from someone who has a special relationship with the elderly individual (spouse, child, friend, or in-home caregiver) that occurs in the home of the elderly or caregiver
  - **Institutional**: occurs in the setting of a facility that is responsible for caring for the elderly, such as a nursing home or long-term care facility
  - **Self-neglect**: The behavior of the elderly individual leads to harm.

Types of abuse in estimated order of occurrence:
- Self-neglect (estimated 50%). The most common form of abuse (2).
- Financial
- Neglect
- Emotional
- Physical
- Sexual
- Taken advantage of: misinformation and unregulated online pharmaceutical, financial companies, and so forth, that specifically target the elderly leading to deleterious outcomes (3)

EPIDEMIOLOGY

Incidence
The incidence in the US is estimated at 10% of the population who have been victims of abuse with some estimates as high as 5 million elders affected each year. Low reporting as noted by one study (1 in 14 cases) makes the true incidence difficult to establish (4). Majority of the victims are likely to be women (5)[A]. Globally the number reported by the World Health Organization is around 15.7% (6).

ETIOLOGY AND PATHOPHYSIOLOGY
The etiology of elder abuse is a complex interplay of biopsychosocial combination of increased dependence on the caregiver by the victim in a suboptimal environment with poor behavioral coping methods, which is compounded by increased stress.

Genetics
Not contributory

RISK FACTORS
- The victim:
  - Advanced age
  - Exploitable resources
  - Prior history of abuse in life
  - Dementia or other cognitive impairment (estimated that nearly 50% will experience abuse
or neglect)
– Female gender
– Disability in caring for him/herself
– Depression
– Social isolation
– Stress: health, financial, or situational

● The abuser:
  – Mental illness
  – Financial dependency
  – Substance abuse
  – History of violence
  – Other antisocial behavior (6)

● 60% of the time the abuser is a family member — adult children or spouses

**GENERAL PREVENTION**

● Improve patient’s social contact and support.
● Identify and correct potential risk factors for elder abuse:
  – Home visit to identify for potential risks of fall hazards and barriers to ambulation that could lead to fractures and functional decline that could leave the individual vulnerable to abuse
  – Evaluate for assistive devices that help the patient independently complete his/her ADLs and prevent caregiver dependence.
  – Screen for depression using validated tools like the Geriatric Depression Scale.
  – Early identification and treatment of cognitive impairment

● Identify caregiver stress and burden; refer to community programs that aid with emotional assistance.

● Advance life directives planning, including identifying possible caregivers, choosing a medical power of attorney (MPOA), estate and will planning, and so forth

**COMMONLY ASSOCIATED CONDITIONS**

Most common associated conditions with elder abuse are also identified as risk factors: social isolation, increased dependence for ADL/IADLs, depression, cognitive impairment, and aggressive behavior (7,8).

**DIAGNOSIS**

A high index of suspicion when risk factors are present is important; types of abuse should be kept in mind as some types might not be obvious. There are very few validated instruments designed to detect the risk or suspicion of elder abuse for the primary care physician. Plus it can be difficult to diagnose elder abuse in a single clinical visit, so team work and assessment of the patient’s home environment can help. It is therefore important to get one’s office/clinic/hospital staff trained to recognize it, have social services involved and to consider doing home visits, when abuse is suspected (7).

**HISTORY**

A detailed history with focus on the living arrangements, degree of functionality, who the caregivers are, and other risk factors listed above. Pay attention to clues such as withdrawal from
normal activities or a sudden change in finances or abrupt changes to a will.

**PHYSICAL EXAM**

- It is important to document positive and negative findings in your physical exam and to be very detailed because it can be admissible in court.
- Vital signs: Check weight and assess for progressive loss in weight
- General overall appearance:
  - Wasting or cachexia
  - Poor hygiene, unkempt clothing
  - If the patient is bedbound, it is important to assess the integrity of the mattress and sheets.
    Look for excessive skin flakes, hair, or urine-soiled mattresses.
- Oral exam:
  - Assess for poor dentition, oral ulcers, or abscesses.
- Skin exam:
  - Most bruises from elder abuse are large (>5 cm) and located on the face, lateral arm, or back.
  - Bite or burn marks
  - It is important to check for pressure ulcers on the bony prominences of the patient: elbows, sacrum, heels, and scapula.
- Mental/psychiatric:
  - Withdrawn, anxious, fearful, blunted—especially in the presence of the abuser

**DIFFERENTIAL DIAGNOSIS**

- Advanced dementia can present with individuals appearing withdrawn, and they are often malnourished.
- Elderly with advanced dementia of Alzheimer type or Lewy body dementia can present with delusions of persecution and aggression that can be confused for elder abuse.
- Patients with Parkinson disease often fall and may exhibit fractures and bruises on a frequent basis that may mimic recurrent physical abuse.
- Coagulopathy seen in patients in advanced malignancy with bone marrow suppression or invasion, and those on chronic antiplatelet therapy, can appear with bruising that can be easily confused with elder abuse.
- Wasting from malignancy, infections, chronic disease
- Thyroid disorder can present with altered mental status (AMS), depression, or anxiety.
- Chronic lung disease can present with decreased weight.
- Delirium from acute electrolyte disturbances, infectious etiology, or cardiovascular compromise can all present similar to elder abuse.
- Impaired financial status can also be confused with self-neglect.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
CBC, Comprehensive Metabolic Profile, UA, Urine culture

**Follow-Up Tests & Special Considerations**
- For Anemia, consider ferritin.
- Macrocytosis: Vitamin B12
- Bruising: PT, INR, bleeding time; Change in Mental Status: B12, syphilis testing, TSH
- Trauma: Imaging to assess for new and old fractures; If physical abuse is suspected and cognitive impairment present, then cranial imaging to look for hemorrhage (e.g., subdural) is indicated using CT scan or MRI.

**Diagnostic Procedures/Other**
- Validated tools to assess for cognitive impairment such as Folstein Mini-Mental State Examination (MMSE), Montreal Cognitive Assessment (MOCA), to assess for cognitive impairment if suspected
- Depression screening tools such as Geriatric Depression Scale or PHQ 9 if suspected
- Documentation
  - Practitioners may make statements of “suspected mistreatment” but should avoid making definitive diagnosis of abuse in their initial assessment, unless it is very obvious.

**TREATMENT**
Most states require all health care providers to report suspected elder abuse to a local agency such as the Adult Protective Services (http://www.nccafv.org/state_elder_abuse_hotlines.htm).

**MEDICATION**
None

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- If the patient is a victim of elder abuse, he/she must be relocated to a safer alternative and may need admission for sequelae caused by the abuse.
- Victims of elder abuse should be admitted to the hospital if there are no safe discharge alternatives.
- Management of uncontrolled chronic conditions due to neglect (i.e., wound care from ulcers or infections)
- Cases of suspected abuse must be reported to the state’s Adult Protective Services agency or a designated alternative (e.g., if patient resides in nursing home, then report to that state’s regulatory entity). Social services may help. If physical harm has occurred, consider reporting to local law enforcement for investigation.
- Hospital security may need to be notified if restricted visitor access to a patient is required, and the patient’s name may be hidden from the public hospital census.
- Victims should not be discharged to a potentially abusive environment. Alternatives to discharge to the unsafe environment may include:
  - Friend or family member
  - Nursing home
  - Personal care home
  - Assisted living facility
  - Local victims’ rescue or sheltering program if available

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Victims of abuse should not be discharged without reliable follow-up, including:

- Primary care physician visit soon after discharge (i.e., within 1 week) with excellent communication between the discharging service and the primary care physician
- Follow-up with Adult Protective Services or other agency; a home visit should be scheduled prior to discharge if the patient is going back home.
- Home Health Agency for assessment of safety (physical therapy)
- Follow-up with appropriate mental health care

**Patient Monitoring**

- The patient should have frequent visits and be followed through the appropriate agencies to reduce continuation of abuse and to identify recurring abuse.
- Financial impact
  - The impact on victims runs in to billions of dollars annually. In 2009, the estimate was approximately $2.9 billion which was a 12% increase from the year preceding (9).

**PATIENT EDUCATION**

- For Elder Abuse Resources in your state, you can go to the National Center of Elder Abuse at [https://ncea.acl.gov](https://ncea.acl.gov)
- Or your local representative by calling 1-800-677-1166

**PROGNOSIS**

Elder abuse and self-neglect are associated with an overall increased risk in mortality, up to 300% higher than their non-abused or neglected cohorts (10).

**COMPLICATIONS**

Complications of elder abuse can lead to worsening depression, increased mortality, and overall poor quality of life.

**REFERENCES**

**ADDITIONAL READING**

- https://ncea.acl.gov/

**CODES**

**ICD10**

- T74.11XA Adult physical abuse, confirmed, initial encounter
- T74.21XA Adult sexual abuse, confirmed, initial encounter
- T74.01XA Adult neglect or abandonment, confirmed, initial encounter

**CLINICAL PEARLS**

- Elder abuse, or elder mistreatment, is a condition in which the physical, psychological, or financial well-being of an older adult is infringed upon through intentional acts or lack of action, even if harm is not intended.
- It is important to identify vulnerable individuals through proper evaluation of potential risk factors for abuse (social isolation, depression, cognitive impairment, disability requiring assistance, and financial dependence by the caregiver).
- Correction of risk factors is important to reduce the incidence of elder abuse (strengthen the patients’ social support, treat depression, provide the patient with assistive devices, screen for cognitive impairment with a trial of medication if possible, and identify caregiver burn out).
Clearly document your physical exam with only specific objective findings.
Contact APS (Adult Protective Services) or your local resources if elder abuse is suspected; it
is generally unlawful not to report suspected elder abuse.


ENCOPRESIS
Jay Fong, MD ● William T. Garrison, PhD

BASICS

DESCRIPTION
- Voluntary or involuntary fecal soilage in a (typically) previously toilet-trained child
  - Age may be chronologic or developmental.
  - No underlying organic disease
  - At least one event per month for 3 months
  - Classified into functional constipation (retentive encopresis) and functional nonretentive fecal incontinence (FNRFI); both cause fecal incontinence. There is no constipation in FNRFI. Functional constipation is more common.
- System(s) affected: GI; psychological
- Synonyms(s): fecal incontinence, soiling

EPIDEMIOLOGY

Incidence
Predominant sex: male > female (4 to 6:1) Constipation accounts for 3% of general pediatric referrals; up to 84% of constipated children have fecal incontinence at some point.

Prevalence
Occurs in 1–3% of children 4 years of age

ETIOLOGY AND PATHOPHYSIOLOGY
- In 90% of cases, encopresis develops as a consequence of chronic constipation, with resulting overflow incontinence (retentive encopresis). The other 10% are caused by specific organic etiologies.
- Chronic constipation with irregular and incomplete evacuation results in progressive rectal distension and stretching of the internal/external anal sphincters.
- Chronic rectal distension causes habituation, leading to the loss of sensing the normal urge to defecate. Eventually, soft or liquid stool leaks around the retained fecal mass.
- Many children voluntarily withhold stool in response to the urge to defecate for fear of pain or a preoccupation with not interrupting social activities.
- Psychological
  - Stool withholding, fear, anxiety
  - Difficulty with toilet training, including unusual anxiety or conflict with parent
  - Resistance to using public toilet facilities, such as school bathrooms or outdoor toilets
  - Known association with sexual abuse in boys; likely similar association in girls
  - Developmental delay
- Anatomic
  - Rectal distension and desensitization
  - Anal fissure or painful defecation
  - Muscle hypotonia
  - Slow intestinal motility
  - Hirschsprung disease
– Cystic fibrosis
– Spinal cord defects (e.g., spina bifida)
– Congenital anorectal malformations
– Anal stenosis
– Anterior displacement of the anus
– Postoperative stricture of anus or rectum
– Pelvic mass
– Neurofibromatosis

• Dietary or metabolic
  – Inadequate dietary fiber
  – Excessive protein or milk intake
  – Inadequate water intake
  – Hypothyroidism
  – Hypercalcemia
  – Hypokalemia
  – Diabetes insipidus; diabetes mellitus
  – Food allergy
  – Gluten enteropathy

• Medication side effects

### Genetics
None known; although incidence may be higher in children with family history of constipation

### RISK FACTORS
• Male gender
• Constipation
• Very low birth weight
• Painful defecation
• Difficulty with bowel training, including social pressure related to early childcare placement
• Organic/anatomic causes
• Anxiety and depression
• Insufficient fluid or fiber intake
• Refusal to use public restrooms
• Attention deficit
• History of abuse

### GENERAL PREVENTION
Family education: toilet training when ready; optimize fluid and fiber intake.

### COMMONLY ASSOCIATED CONDITIONS
• Constipation, Hirschsprung disease
• Cerebral palsy, cystic fibrosis
• Developmental and behavioral diagnoses, urinary incontinence

### DIAGNOSIS

### HISTORY
Signs/symptoms of constipation:
- Hard, large-caliber stools
- <3 defecations per week
- Pain or discomfort with stool passage
- Withholding stool
- Blood on stool or in diaper/toilet bowl
- Decreased appetite
- Abdominal pain that improves with stool passage
- Hiding while defecating before child is toilet-trained; avoiding use of the toilet
- Diet low in fiber or fluids, high in dairy products
- No stool passage in the first 48 hours of life
- Pasty stool on underclothes
- Recurrent UTIs
- Abrupt onset after age 5 years more likely to be associated with psychological trauma.
- Overlap with attention deficit disorder (ADD) common in children >5 years
- Medication use: opiates, phenobarbital, and tricyclic antidepressants (TCAs)
- Family history of constipation

PHYSICAL EXAM
- Neurologic exam of lower extremities and perineal area, with attention to S1–S4 distribution, perineal sensation, cremasteric reflex, and anal sphincter tone
- Genital examination and digital rectal exam: Assess for anal fissures, sphincter tone, rectal distension/impaction, occult or visible blood.
- Abdominal exam: bowel sounds, percussion note (tympany), abdominal distension; palpate for stool (most common in left lower quadrant)

DIAGNOSTIC TESTS & INTERPRETATION
Most cases diagnosed by history and physical.

Initial Tests (lab, imaging)
Used only to rule out organic causes.
- UA/urine culture: UTI/glucosuria
- Thyroid function tests: hypothyroidism
- Electrolyte panel, including calcium: hypokalemia, hypercalcemia, or hyperglycemia
- Abdominal plain films if impaction is suspected and not detected by abdominal or rectal exam

Follow-Up Tests & Special Considerations
- Failure to pass meconium within 48 hours of birth, failure to thrive, bloody diarrhea, or bilious vomiting in a neonate should be promptly evaluated to exclude aganglionic megacolon.
- Constipation and diarrhea, rash, failure to thrive, or recurrent pneumonia should prompt evaluation for cystic fibrosis. Patients with abdominal distension or ileus should be evaluated for possible obstruction.

Diagnostic Procedures/Other
Manometric studies may be useful in patients who have constipation that does not respond to treatment.
**TREATMENT**

**GENERAL MEASURES**
- Anticipatory toilet training advice about when children should reduce reliance on diapers or use pull-ups during the daytime hours (average age for toilet training in girls is 29 months; 31 months for boys)
- Eliminate impaction prior to maintenance therapy.
- Avoid frequent and repeated rectal exams, enemas, and suppositories, especially in infants.
- Once stools are regular in frequency, child should sit on toilet BID at the same time each day for 10 to 15 minutes and for 10 to 15 minutes after meals. Incorporate positive reinforcement for successful bowel movements.

**MEDICATION**
- Remove impaction and start maintenance treatment.
- No randomized, controlled studies have compared methods of disimpaction: can use oral agents, enemas, and rectal suppositories; oral agents are least traumatic. Glycerin suppositories are best option for infants.

**First Line**
- Disimpaction with polyethylene glycol (PEG)
  - Give 17 g (240 mL) water or juice: 1.0 to 1.5 g/kg/day for 3 days for disimpaction
  - 0.4 to 0.8 g/kg/day for maintenance
- Disimpaction with mineral oil for child >1 year; give 15 to 30 mL/year of age to max 240 mL.
  - Maintenance: 1 to 3 mL/kg/day or divided BID
  - May mix with orange juice to make palatable; avoid in infants to avoid aspiration pneumonia.
- Other maintenance regimens include the following:
  - Milk of magnesia (MOM) 400 mg (5 mL): 1 to 2 mL/kg/day BID
  - Lactulose 10 g (15 mL): 1 to 3 mL/kg/day divided BID
  - Senna syrup 8.8 g sennoside (5 mL): age 2 to 6 years: 2.5 to 7.5 mL/day divided BID; age 6 to 12 years: 5 to 15 mL/day divided BID
  - Bisacodyl suppository 10 mg: 0.5 to 1 suppository once or twice per day

**ISSUES FOR REFERRAL**
If symptoms do not improve after 6 months of compliance with a multifactorial treatment model, refer to pediatric gastroenterologist for further evaluation and guidance.

**ADDITIONAL THERAPIES**
Behavioral treatment and counseling

**SURGERY/OTHER PROCEDURES**
If ongoing constipation is refractory to a combination of medical and behavioral therapy, consider anorectal manometry to evaluate for internal anal sphincter achalasia (or ultrashort-segment Hirschsprung disease). If present, this condition can be treated successfully in most patients with an internal sphincter myectomy.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Children with volitional stool holding who receive behavioral treatment in addition to
medications are more likely to have resolution of encopresis at 3 and 6 months than with medication alone (1)[A].

- No evidence that biofeedback training adds benefit to conventional treatment for functional fecal incontinence in children (2)[A]
- Behavioral interventions combined with laxative therapy (rather than laxative therapy alone) improve continence in children with functional fecal incontinence associated with constipation (1)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization
  - Continued soiling and recurrent impaction on outpatient medical therapy, whether from lack of medication efficacy or patient nonadherence
  - Decreased intake leading to malnutrition or dehydration
  - Recalcitrant vomiting or concern for obstruction
  - Involve appropriate agencies if concern for abuse.
  - Hospital admission and abdominal films may be necessary to ensure complete removal of impaction. This may include direct gastric administration of balanced electrolyte–PEG solutions if the patient cannot tolerate by mouth. Serial abdominal films and observation of rectal effluent can help determine treatment adequacy.
  - IV fluids if the patient is dehydrated and has difficulty tolerating oral intake
  - Nursing to document stool output and character

- Discharge criteria
  - Stools that are looser in consistency and clearer in appearance are a successful inpatient end point.
  - Abdominal radiographs showing less fecal loading (compared with a pretreatment radiograph) with improving serial abdominal exams

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Continue maintenance treatment for 6 months to 2 years with visits every 4 to 10 weeks for support and to ensure compliance; more frequent visits with oppositional or anxious children
- Telephone or virtual visits can be used to adjust doses and to provide ongoing encouragement.
- Treat recurrences of impaction promptly.
- Emphasize compliance with medication and self-initiation of regular bathroom visits.
- Children who do not progress using a well-designed behavior plan should be referred for more in-depth mental health evaluation and counseling.

DIET

Adequate fluid and fiber intake (2)[A]. Reduce cow’s milk products. Avoid excessive consumption of bananas, rice, apples, and gelatin.

PATIENT EDUCATION

- Demystify defecation.
- Carefully explain the treatment plan including medications and dietary changes.
Avoid punishment for inadvertent soiling.
In children >4 years of age, explain to parents how overreliance on diapers and pull-ups (while convenient) can prolong the problem.
Always attempt to use positive reinforcement for successful toilet sits and medication compliance.
If positive approach is unsuccessful, consider removing desired privileges (e.g., TV, video games) for noncompliance with behavioral plan. Some children respond well to a token economy (earned privileges) to promote desired behavior.
Encourage regular physical activity.

PROGNOSIS
Many children exhibit a good response and relapse due to parental noncompliance.
From 30% to 50% of children may still have encopresis after 5 years of treatment.
Children with psychosocial or emotional problems preceding the encopresis are more recalcitrant to treatment.

COMPLICATIONS
- Colitis due to excessive enema/suppository
- Perianal dermatitis
- Anal fissure

REFERENCES

ADDITIONAL READING

CODES

ICD10
- R15.9 Full incontinence of feces
- R15.1 Fecal smearing
F98.1 Encopresis not due to a substance or known physiol condition

**CLINICAL PEARLS**

- 90% of encopresis results from chronic constipation.
- Address toddler constipation early by decreasing excessive milk intake, increasing fruits/vegetables intake, and ensuring adequate fluid and fiber intake.
- Eliminate fecal impaction before initiating maintenance therapy.
ENDOCARDITIS, INFECTIVE
Theodore B. Flaum, DO, FACOFP ● Samantha Faryn Gottlieb, DO, MS

BASICS
Infective endocarditis is a noncontagious infection of the heart, including valves (native or prosthetic), the endocardium and septal defects. Infective endocarditis occurs worldwide and is generally fatal if left untreated.

DESCRIPTION
- An infection of the valvular (primarily) and/or mural (rarely) endocardium
- System(s) affected: cardiovascular, endocrine/metabolic, hematologic/lymphatic, immunologic, pulmonary, renal/urologic, skin/exocrine, neurologic
- Synonym(s): bacterial endocarditis; subacute bacterial endocarditis (SBE); acute bacterial endocarditis (ABE)

EPIDEMIOLOGY
More common in males (3:1). 50% of cases occur in individuals over the age of 50.

Incidence
- Incidence rose in the United States from 11/100,000 in 2000 to 15/100,000 in 2011.
- 1.5–3% incidence 1 year after prosthetic valve replacement; 3–6% 5 years postreplacement
- Increasing incidence of cardiovascular device–related infections due to higher frequency of implantable devices, especially in the elderly
- Can be community or hospital acquired.

ETIOLOGY AND PATHOPHYSIOLOGY
- ABE: Staphylococcus aureus; Streptococcus groups A, B, C, G; Streptococcus pneumoniae; Staphylococcus lugdenensis; Enterococcus spp. (gram-positive); Haemophilus influenzae or parainfluenzae; Neisseria gonorrhoeae (gram-negative)
- SBE: α-hemolytic streptococci (viridans group strep), Streptococcus bovis, Enterococcus spp., S. aureus, Staphylococcus epidermidis (gram-positive); HACEK organisms: Haemophilus aphrophilus or paraphrophilus, Actinobacillus (Aggregatibacter) actinomycetemcomitans, Cardiobacterium hominis, Eikenella corrodens, Kingella kingae
- Endocarditis in IV drug abusers (tricuspid valve): S. aureus, Enterococcus spp. (gram-positive); Pseudomonas aeruginosa, Burkholderia cepacia, other bacilli (gram-negative); Candida spp.
- Early prosthetic valve endocarditis (<60 days after valve implantation): S. aureus, S. epidermidis (gram-positive); gram-negative bacilli; fungi: Candida spp., Aspergillus spp.
- Late prosthetic valve endocarditis (>60 days after valve implantation): α-hemolytic streptococci, Enterococcus spp., S. epidermidis (gram-positive); Candida spp., Aspergillus spp.
- Culture-negative endocarditis: 10% of cases; Bartonella quintana (homeless); Brucella spp., fungi, Coxiella burnetii (Q fever), Chlamydia trachomatis, Chlamydophila psittaci, HACEK organisms; Abiotrophia (formerly vitamin B₆–deficient streptococci); use of antibiotics prior
to blood cultures

- Device-related endocarditis: coagulase-negative staphylococci or S. aureus

**RISK FACTORS**

- Injection drug use, IV catheterization, certain malignancies (colon cancer), poor dentition, chronic hemodialysis
- High risk with:
  - Prosthetic cardiac valve, implantable devices (pacemaker, automatic implantable-cardioverter defibrillator [AICD]), total parenteral nutrition
  - Previous infective endocarditis (IE)
  - Congenital heart disease (CHD): unrepaired cyanotic CHD, including palliative shunts and conduits; repaired CHD with prosthetic device during the first 6 months; repaired CHD with residual defects at or near prosthetic site; cardiac transplant with valvulopathy

**GENERAL PREVENTION**

- Good oral hygiene
- Antibiotic prophylaxis is only recommended for high-risk cardiac conditions—prosthetic heart valve, history of endocarditis, transplant with abnormal valvular function, CHD (see “Risk Factors”).
- Procedures requiring prophylaxis
  - Oral/upper respiratory tract: any manipulation of gingival tissue or periapical region of teeth or perforation of the oral mucosa; invasive respiratory procedures involving incision; or biopsy of the respiratory mucosa merit prophylaxis. Amoxicillin 2 g PO (if penicillin allergic, clindamycin 600 mg PO) 30 to 60 minutes before procedure or ampicillin 2 g IV/IM are first-line prophylactic choices. For penicillin-allergic patients, use clindamycin 600 mg IV, or cephalexin 2 g PO, or azithromycin/clarithromycin 500 mg PO, or cefazolin/ceftriaxone 1 g IV/IM 30 minutes before procedure. Pediatric doses are amoxicillin 50 mg/kg PO (max 2 g), cephalexin 50 mg/kg PO (max 2 g), clindamycin 20 mg/kg PO (max 600 mg), and ampicillin or ceftriaxone 50 mg/kg (maximum 1 g) IM/IV.
  - GI/GU: Only consider coverage for Enterococcus (with penicillin, ampicillin, piperacillin, or vancomycin) for patients with an established infection undergoing procedures.
  - Cardiac valvular surgery or placement of prosthetic intracardiac/intravascular materials: perioperative cefazolin 1 to 2 g IV 30 minutes preoperative or vancomycin 15 mg/kg (maximum 1 g) (penicillin-allergic patients) 60 minutes preoperative.
  - Skin: incision and drainage of infected tissue; use agents active against skin pathogens (e.g., cefazolin 1 to 2 g IV q8h or vancomycin 15 mg/kg q12h; max 1 g) if penicillin-allergic or if methicillin-resistant S. aureus (MRSA) suspected.

**COMMONLY ASSOCIATED CONDITIONS**

Infectious agents have an affinity for defective tissue. Therefore, most patients with infective endocarditis have preexisting conditions/procedures such as structural heart disease, valvular disease, congenital heart disease, prosthetic heart valves, transcatheter aortic valve replacement, intravascular device and cardiac implantable electronic device. Patients with a history of endocarditis also have an increased risk for recurrence due to the damaged tissue from the previous infection. Patients undergoing chronic hemodialysis have an increased occurrence of infective endocarditis due to increased frequency of introduction of foreign material into the body. HIV is commonly associated with infective endocarditis due to immunocompromised
DIAGNOSIS

- Modified Duke Criteria [1][B] (definite: 2 major criteria, or 1 major and 3 minor criteria, or 5 minor criteria; possible: 1 major and 1 minor or 3 minor criteria)
  - Major clinical criteria
    - Positive blood culture: isolation of typical microorganism for IE from two separate blood cultures or persistently positive blood culture
    - Single positive blood culture for C. burnetii or anti–phase-1 IgG antibody titer >1:800
    - Positive echocardiogram: presence of vegetation, abscess, or new partial dehiscence of prosthetic valve; must be performed rapidly if IE is suspected.
    - New valvular regurgitation (change in preexisting murmur not sufficient)
  - Minor criteria
    - Predisposing heart condition or IV drug use
    - Fever ≥38.0°C (100.4°F)
    - Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysm, intracranial hemorrhage, conjunctival hemorrhage, Janeway lesions
    - Immunologic phenomena: glomerulonephritis, Osler nodes, Roth spots, rheumatoid factor (RF)
    - Microbiologic evidence: positive blood culture not a major criterion (excluding single positive cultures for coagulase-negative staphylococci and organisms that do not cause endocarditis) or serologic evidence of infection likely to cause IE

HISTORY

- Fever (>38°C), chills, cough, dyspnea, orthopnea; especially in subacute endocarditis: night sweats, weight loss, fatigue
- Review risk factors.
- Symptoms of transient ischemic attack, cerebrovascular accident (CVA), or myocardial infarction (MI) on presentation

PHYSICAL EXAM

- Most patients with IE have new murmur or a change in an existing murmur. Signs of heart failure (rales, edema) are common if valve function is compromised
- Peripheral stigmata of IE: splinter hemorrhages in fingernail beds, Osler nodes on fleshy portions of extremities, “Roth spot” retinal hemorrhages, Janeway lesions (cutaneous evidence of septic emboli), palatal or conjunctival petechiae, splenomegaly, hematuria (due to emboli or glomerulonephritis)
- Neurologic findings consistent with CVA, such as visual loss, motor weakness, and aphasia

DIFFERENTIAL DIAGNOSIS

- Fever of unknown origin, infected central venous catheter, marantic endocarditis, connective tissue diseases, intra-abdominal infections, rheumatic fever, salmonellosis, brucellosis, malignancy, tuberculosis, atrial myxoma, septic thrombophlebitis

DIAGNOSTIC TESTS & INTERPRETATION

- If not critically ill; three sets of blood cultures drawn >2 hours apart from different sites before
administration of antibiotics

- If acutely ill, draw three sets of blood cultures over 1 hour prior to empiric therapy (1)[A].
- Leukocytosis is common in acute endocarditis.
- Anemia; decreased C3, C4, CH50; and RF in subacute endocarditis
- ESR, C-reactive protein (CRP)
- Hematuria, microscopic or macroscopic
- Consider serologies for Chlamydia, Q fever, Legionella, and Bartonella in “culture-negative” endocarditis.
- Transthoracic (TTE) or transesophageal echocardiogram (TEE [preferred]) should be performed as soon as IE is suspected (1)[A].
- CT scan may help locate embolic abscesses (e.g., spleen).
- Vegetations are composed of platelets, fibrin, and colonies of microorganisms. Destruction of valvular endocardium, perforation of valve leaflets, rupture of chordae tendineae, abscesses of myocardium, rupture of sinus of Valsalva, and pericarditis may occur.
- Emboli, abscesses, and/or infarction of any system
- Immune-complex glomerulonephritis

**TREATMENT**

**MEDICATION**

**First Line**
- Start empiric treatment after three sets of blood cultures have been drawn. Results guide treatment.
  - Native valves: ampicillin-sulbactam 12 g/day IV divided into 4 doses with gentamicin 3 mg/kg/day IV/IM in 2 or 3 doses. If penicillin-allergic, use vancomycin 30 mg/kg/day IV in 2 doses with gentamicin 3 mg/kg/day IV/IM in 2 or 3 doses and with ciprofloxacin 1,000 mg/day PO or 800 mg/day IV in 2 doses (2)[A].
  - Prosthetic valves: vancomycin 30 mg/kg/day IV in 2 doses with gentamicin 3 mg/kg/day IV/IM in 2 doses and rifampin 1,200 mg/day PO in 2 doses, if <12 months postsurgery. If >12 months, use native valve regimen (2)[A].
- Penicillin-susceptible viridans streptococci or S. bovis
  - Native valve: penicillin G 12 to 18 million U/day IV continuously or in 4 to 6 doses or ceftriaxone 2 g/day IV/IM in 1 dose, both for 4 weeks (1)[B]
  - Prosthetic valve: penicillin G 24 million U/day IV continuously or in 4 to 6 doses for 6 weeks or ceftriaxone 2 g/day IV/IM in 1 dose ± gentamicin 3 mg/kg IV/IM q24h for 2 weeks (peak gentamicin level 3 μg/mL and trough <1 μg/mL) (1)[B]
- Penicillin-resistant viridans streptococci or S. bovis
  - Native valve: penicillin G 24 million U/day IV, either continuously or in 4 to 6 equally divided doses + gentamicin 3 mg/kg IV/IM q24h for 2 weeks (peak gentamicin level 3 μg/mL and trough <1 μg/mL) (1)[B]
  - Prosthetic valve: penicillin G 24 million U/day IV, either continuously or in 4 to 6 equally divided doses or ceftriaxone 2 g/day IV/IM in 1 dose for 6 weeks + gentamicin 3 mg/kg IV/IM q24h for 2 weeks (peak gentamicin level 3 μg/mL and trough <1 μg/mL) (1)[B]

Staphylococcus
- Native valve: oxacillin or nafcillin 12 g IV/day in 4 to 6 equally divided doses for 6 weeks.
For oxacillin-resistant strains, use vancomycin 15 mg/kg/day IV q12h for 6 weeks for goal trough of 15 to 20 μg/mL (1)[B].

- Prosthetic valve: oxacillin or nafcillin 12 g/day IV in 4 to 6 doses + rifampin 300 mg IV/PO q8h, for 6 weeks, + gentamicin 3 mg/kg/day IV for first 2 weeks (peak gentamicin level 3 μg/mL and trough <1 μg/mL). For oxacillin-resistant strains, use vancomycin 15 mg/kg IV q12h, + rifampin 300 mg IV/PO q8h, both for 6 weeks, + gentamicin 3 mg/kg/day IV/IM in 2 to 3 doses for the first 2 weeks (peak gentamicin level 3 μg/mL and trough <1 μg/mL) (1)[B].

- Penicillin-sensitive Enterococcus, native or prosthetic valve: ampicillin 2 g IV q4h or penicillin G 18 to 30 million U/day IV continuously or in 6 doses + gentamicin 3 mg/kg IV q8h for 4 to 6 weeks (peak gentamicin level 3 μg/mL and trough <1 μg/mL) (1)[B]. Consider expert consultation for penicillin-resistant enterococci.

- HACEK organisms: ceftriaxone 2 g IM or IV q24h for 4 weeks (1)[B] or ampicillin-sulbactam 12 g IV q4h for 4 weeks or ciprofloxacin 1 g/day PO or 800 mg/day IV in 2 equally divided doses for 4 weeks (1)[B]
  
- Cardiac device–related endocarditis: device removal followed by antibiotic therapy based on organism susceptibility (3)[B].

Precautions: Adjust dosage of penicillin G, gentamicin, cefazolin, ampicillin, ampicillin/sulbactam, ciprofloxacin, and vancomycin in patients with renal impairment. Rapid infusion of vancomycin <1 hour may cause “red-man syndrome” due to histamine release (not an allergic reaction). Treat with antihistamines and decrease infusion rate.

Interactions: Vancomycin + gentamicin increases renal toxicity. Rifampin alters warfarin and oral hypoglycemic metabolism.

**Second Line**

For patients allergic to penicillin:

- Penicillin-susceptible or resistant viridans group streptococci or S. bovis: vancomycin 30 mg/kg/day (not to exceed 2 g/day) IV in 2 equal doses for 4 weeks (6 weeks for prosthetic valve endocarditis) for goal trough of 10 to 15 μg/mL (1)[B]

- Enterococcus, native or prosthetic valve: Desensitization to penicillin should be considered; vancomycin 15 mg/kg (usual dose, 1 g) IV q12h + gentamicin or streptomycin (peak gentamicin level 3 μg/mL and trough <1 μg/mL) for 4 to 6 weeks (6 weeks for prosthetic valve endocarditis) (1)[B]

- Staphylococcus of native valve: cefazolin 2 g IV q8h (not to be used in patients with immediate-type hypersensitivity to penicillin) for 6 weeks or vancomycin 30 mg/kg (usual dose, 1 g) IV q12h for a goal trough of 15 to 20 μg/mL for 6 weeks (1)[B]

**SURGERY/OTHER PROCEDURES**

Surgery is required in 50% of IE cases. Indications (2)[A]:

- Heart failure due to aortic or mitral valve disease
  
  - Prevention of embolism: aortic or mitral valve vegetations >10 mm with prior embolic episodes; isolated very large vegetation >15 mm; in patients with major ischemic stroke, surgery is delayed for at least 4 weeks, if possible (4)[C].

- Uncontrolled infection: persistent fever and positive cultures >7 to 10 days; infection caused by fungi or resistant organism; presence of abscess, fistula, false aneurysm, or enlarging vegetations

- Early prosthetic valve IE
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Check gentamicin peak (~3 μg/mL) and trough (<1 μg/mL) levels if used for >5 days and with renal dysfunction. Perform twice-weekly BUN and serum creatinine while on gentamicin. Consider audiometry baseline and follow-up during long-term aminoglycoside therapy (2).
- Check vancomycin trough (15 to 20 μg/mL) levels in all patients (typically prior to fourth dose) (2) [B].
- Baseline ECG; monitor ECG for conduction disturbances/MI in initial weeks of therapy.
- TTE at the conclusion of therapy
- Blood cultures q48h until negative

PROGNOSIS
The one year mortality of infective endocarditis is 30%. Late complications contribute to poor prognosis. These include heart failure, re-infection, and cerebral emboli. 10-year survival is 60–90% (5) [A].

COMPLICATIONS
- Cerebral complications are the most frequent and severe, occurring in 15–20% of patients (1) [A].
- Emboli: arterial (e.g., MI, mesenteric, splenic, cerebral infarction), infectious (e.g., abscesses of heart, lung, brain, meninges, bone, pericardium)
  - Neurologic events are the most frequent complications in patients with IE requiring ICU admission. Ischemic stroke is the presenting symptom of IE in 20% of cases (5) [A].
- Inflammatory/immune disorders (e.g., arthritis, myositis, glomerulonephritis)
- Other complications: congestive heart failure (CHF), ruptured valve cusp, sinus of Valsalva aneurysm, arrhythmia, and mycotic aneurysms

REFERENCES
4. Byrne JG, Rezai K, Sanchez JA, et al. Surgical management of endocarditis: the society of

CODES

ICD10
- I33.0 Acute and subacute infective endocarditis
- I39 Endocarditis and heart valve disorder in class elsewhere
- A54.83 Gonococcal heart infection

CLINICAL PEARLS
- Antibiotic prophylaxis is recommended for patients with artificial heart valves, a previous history of infective endocarditis, congenital heart disease, and cardiac transplants with valvulopathy.
- TEE/TTE and blood cultures are the mainstays for diagnosing IE.
- The most commonly identified organisms are viridans Streptococcus species and Staphylococcus (3,4,5).
ENDOMETRIAL CANCER AND UTERINE SARCOMA
Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION
- Endometrial cancer: malignancy of the endometrial lining of the uterus
  - Two types
    - Type I: estrogen-dependent, grade 1 or grade 2, better prognosis, endometrioid histology
    - Type II: estrogen-independent, higher grade, more aggressive, includes grade 3
      endometrioid and nonendometrioid: serous, clear cell, mucinous, poor prognosis (1)[A]
- Cell types: adenocarcinoma, adenosquamous (malignant squamous elements), clear cell, and papillary serous
- Sarcomas: malignancy of the uterine mesenchyme and mixed tumors
  - Mixed müllerian sarcoma (carcinosarcoma): Heterologous sarcoma elements are not native to the müllerian system (e.g., cartilage or bone); homologous sarcoma elements are native to the müllerian system (40–50% prevalence of all sarcomas).
  - Leiomyosarcoma develops in the myometrium, characterized by cellular atypic mitoses and coagulative necrosis (30% prevalence of all sarcomas).
  - Endometrial stromal sarcoma develops from the stromal component of the endometrium (15% prevalence of all sarcomas).
    - Poorer prognosis (2)[C]
- Predominant age
  - Endometrial cancer: Most patients are postmenopausal:
    - Average age of diagnosis: 63 years old
  - Sarcomas: occur in both pre- and postmenopausal:
    - Average age of diagnosis: 40 to 69 years old (2)[C]
- 70% of endometrial cancer is stage I at the time of diagnosis.
- System(s) affected: reproductive
- Synonym(s): uterine cancer; endometrial cancer; corpus cancer

Pregnancy Considerations
This malignancy is not associated with pregnancy.

EPIDEMIOLOGY

Incidence
- Endometrial cancer is the most common gynecologic malignancy, fourth most common cancer in women, and eighth leading cause of cancer-related death in women worldwide.
- In the United States, it is estimated that endometrial cancer will account for 61,380 new cases and 10,920 deaths in 2017 according to SEER database.
- Incidence higher in Caucasian than African American, but African Americans have stage matched higher mortality (3).

Prevalence
Approximately 500,000 women in the United States
ETIOLOGY AND PATHOPHYSIOLOGY
Continuous estrogen stimulation unopposed by progesterone

- Endometrial: unopposed estrogen
  - Estrogen replacement therapy without concomitant progesterone increases the risk. Addition of progesterone decreases risk to that of general population.
- Sarcomas: etiology unknown

Genetics

- Endometrial: Lynch syndrome (hereditary nonpolyposis colorectal cancer); lifetime risk up to 30% (3); Cowden syndrome (4,5)
- Sarcoma: African American, higher incidence of leiomyosarcoma, childhood retinoblastoma survivors

RISK FACTORS

- Early menarche/late menopause
- Nulliparity
- Personal or family history of colon or reproductive system cancer
- Obesity
- Diabetes mellitus
- Hypertension
- Polycystic ovarian syndrome
- Increasing age
- Estrogen-secreting tumor
- Endometrial hyperplasia
- Unopposed estrogens
- Tamoxifen use

GENERAL PREVENTION

- In young women who are obese or anovulatory, the risk of endometrial cancer can be reduced by taking oral contraceptive pills, permanently losing weight, or taking cyclic progesterone to prevent unopposed estrogen’s effects on the uterus.
- Estrogen replacement therapy should always include progesterone unless the woman has had a hysterectomy.
- Cigarette smoking has been associated with a lower risk of type I endometrial cancer; however, it is not recommended secondary to its many health risks and increase risk of type II endometrial cancer.

COMMONLY ASSOCIATED CONDITIONS

- Endometrial hyperplasia: 1–25% will progress to endometrial adenocarcinoma:
  - Simple without atypia
  - Complex without atypia
  - Simple with atypia
  - Complex with atypia
    - 43% with complex hyperplasia with atypia have concurrent endometrial cancer.
- Endometrial cancer patients should be screened regularly for breast and colon cancer per routine screening guidelines.
- Patients who have breast or colon cancer are at increased risk for endometrial cancer.
- Granulosa cell tumors of the ovary produce estrogen; these patients will have an increased risk
of endometrial cancer.

DIAGNOSIS

HISTORY
- Endometrial cancer
  - Postmenopausal bleeding is the most frequent sign. Any spotting or abnormal discharge mandates evaluation.
  - Premenopausal patients with history of anovulation and heavy, irregular, or prolonged periods that fail multiple medical managements mandate evaluation.
- Sarcoma
  - Mixed müllerian sarcoma: bleeding and prolapsing tissue, pain (2)[C]
  - Leiomyosarcoma: pelvic pain, pressure, uterine mass, abnormal bleeding

PHYSICAL EXAM
Pelvic exam: enlarged uterus, fixed

DIFFERENTIAL DIAGNOSIS
- Atypical complex hyperplasia: a premalignant lesion of the endometrium
- Cervical cancer
- Ovarian cancer invading the uterus
- Endometriosis
- Adenomyosis
- Leiomyoma

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Liver and renal function tests
- Transvaginal ultrasound usually shows increased endometrial thickness (>4 mm in postmenopausal patients or in patients with irregular or heavy periods if >35 years of age, 100% NPV) (1)[A].
- Levels of cancer antigen 125 (CA-125) may be elevated when intra-abdominal disease is present (1)[A].
- Chest x-ray (CXR): Most common site of metastases is the lung.
- Mammogram and colonoscopy: Endometrial cancer is associated with breast and colon cancer.
- Routine preoperative MRI, CT, or PET scan: not recommended (3)

Follow-Up Tests & Special Considerations
- Endometrial cancer is mostly localized to the uterus; therefore, preoperative evaluation for metastasis is not needed unless metastasis is already suspected (2)[A].
- CT scan, PET/CT, MRI, CA-125: not part of the routine evaluation but may be needed if metastasis is suspected, patient is a poor operative candidate, or pathology returns high grade (G3 endometrioid, papillary serous, clear cell, carcinosarcoma) (2)
- MRI has been reported to show the depth of myometrial penetration accurately but is not always cost-effective (6)[A].

Diagnostic Procedures/Other
Office endometrial biopsy (90% accurate): If negative with high suspicion for cancer or patient continues to have bleeding, a dilation and curettage (D&C) is necessary (2)[B]. Endometrial stromal sarcoma and leiomyosarcoma rarely are diagnosed preoperatively. Any patient with history of irregular, heavy, or prolonged periods should undergo endometrial biopsy prior to endometrial ablation procedures.

- Fractional D&C is 99% accurate except in cases of sarcoma.
- If surgical approach is favored, D&C with hysteroscopic guidance is recommended over D&C alone, due to its ability to pick up discrete lesions (2)[A].
- Meta-analyses suggest hysteroscopic peritoneal dissemination of malignant cells; unknown significance of that dispersion

**Test Interpretation**

- International Federation of Gynecology and Obstetrics Staging System: revised 2009
  - Stage I (confined to corpus uteri)
    - A: No or <1/2 myometrial invasion
    - B: Invasion ≥1/2 the myometrium
  - Stage II: Tumor invades cervical stroma but does not extend beyond the uterus.
  - Stage III: Local and/or regional spread
    - A: Uterine serosal and/or adnexal invasion
    - B: Vaginal and/or parametrial involvement
    - C: Metastases to pelvic and/or para-aortic lymph nodes
      - IIIA1: +Pelvic nodes
      - IIIC2: +Para-aortic lymph nodes positive pelvic lymph nodes
  - Stage IV: Tumor invades bladder and/or bowel mucosa and/or distant metastases:
    - A: Tumor invades bladder and/or bowel mucosa.
    - B: Distant metastases, including intra-abdominal metastases and/or inguinal lymph nodes (1)[A]

- Uterine sarcoma criteria for diagnosis: mitotic index, cellular atypia, and areas of coagulative necrosis separated from tumor (7)[C]

**TREATMENT**

**GENERAL MEASURES**

- Main treatment for uterine cancer is surgery.
- Radiation is used to prevent tumor recurrence at the vaginal cuff.

**MEDICATION**

**First Line**

- Endometrial
  - Chemotherapy for advanced or recurrent disease incurable with surgery and radiation
    - Paclitaxel + carboplatin (2)[B]
    - Doxorubicin + cisplatin + paclitaxel
- Hormonal therapy
  - Medroxyprogesterone acetate: for recurrence or metastases
  - Megestrol (Megace) 160 mg/day for at least 2 months for women with premalignant lesions, atypical complex hyperplasia, or well-differentiated endometrial cancer in patients desiring
fertility. Follow with D&C to determine cancer resolution.
– Levonorgestrel-containing intrauterine device: as mentioned earlier for patients who desire future fertility

- Sarcoma
  - Chemotherapy
    - Doxorubicin as single agent or in combination (7)[A]
- Hormonal
  - Tamoxifen or aromatase inhibitors; not fully studied, +/- progesterone
  - Progesterones

**ADDITIONAL THERAPIES**
Radiation therapy
- Nonoperative candidates: radiation therapy alone
- Low risk: no adjuvant radiation therapy
- Intermediate risk: Consider adjuvant vaginal brachytherapy; reduces local recurrences but has no effect on overall survival
- Vaginal brachytherapy is equivalent to whole pelvic radiation in regard to overall survival (3).
- High risk: chemotherapy and radiation therapy in some cases (6,8)[A]

**SURGERY/OTHER PROCEDURES**
Surgical staging
- Extraperitoneal hysterectomy and bilateral salpingo-oophorectomy
- Cytologic washings
- Pelvic and para-aortic lymph node dissection
- Omental sampling, as indicated, and for papillary serous (3)
- Optimal tumor debulking (1)[A], survival advantage
- LAP2 trial: minimally invasive and laparotomy similar 5-year survival (3)

**Geriatric Considerations**
Older (and obese) patients may be at high risk for surgery. Alternative radiation or progesterone therapy can be considered.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission criteria/initial stabilization
  - Excessive vaginal bleeding
  - Preoperative stabilization
- Nursing: routine; ensure postoperative pain is controlled.
- Postsurgical criteria: pain controlled, tolerating diet, ambulating, and voiding

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Follow-up visit with speculum and rectovaginal exam every 3 to 6 months for 2 years, then every 6 months for 3 years, and then annually for life (2)[C]

**Patient Monitoring**
- Annual CXR is no longer recommended.
CT scan or PET/CT scan of the chest, abdomen, and pelvis should be used only to investigate suspicion of recurrent disease, not routinely.

Control comorbid conditions.

**DIET**
As tolerated and according to comorbidities

**PATIENT EDUCATION**
After surgery:
- No intercourse for ~6 weeks
- No lifting >10 to 15 lb
- No driving until pain free
- Do not expect resumption of full activity for 6 weeks.

**PROGNOSIS**
5-year survival rates

(Uterine adenocarcinoma)

(Uterine carcinosarcoma)

**COMPLICATIONS**
- Surgical: excessive bleeding, wound infection, lymphedema, deep vein thrombosis (DVT), and damage to the urinary or intestinal systems
- Radiation: diarrhea, ileus, bowel obstruction or fistula, radiation cystitis, proctitis, vaginal stenosis, DVT
- Chemotherapy: per the drug given

**REFERENCES**

SEE ALSO
- Cervical Malignancy
- Algorithm: Pelvic Pain

CODES

ICD10
- C54.1 Malignant neoplasm of endometrium
- C55 Malignant neoplasm of uterus, part unspecified
- C54.2 Malignant neoplasm of myometrium

CLINICAL PEARLS
- Most common presenting symptom is abnormal uterine bleeding.
- Any patient with history of irregular, heavy, or prolonged periods should undergo endometrial biopsy.
- Primary cause is unopposed estrogen.
- Endometrial thickness on transvaginal ultrasound of <5 mm makes endometrial cancer very unlikely.
- Primary treatment is with surgery, with possible chemotherapy ± radiation.
ENDOMETRIOSIS
Kimberly S. Tustison, MD • Maegen V. Dupper, MD • Kenneth A. Ballou, MD, FAAFP

BASICS

DESCRIPTION
- Endometriosis is a common but potentially painful and debilitating estrogen-dependent gynecologic condition affecting women of predominately reproductive age (1).[A]
- Symptoms and signs generally consist of pelvic pain, pelvic mass, and/or decreased fertility.
- Due to estrogen-dependent implants of endometrial tissue found outside the uterus. Although endometriomas have been recorded in liver, bowel, umbilicus, lung, and other tissue, the most common pathologic sites are:
  - Peritoneum (bladder, cul-de-sac, pelvic walls, ligaments, and fallopian tubes)
  - Ovaries
  - Rectovaginal septum
- Ectopic endometrial implants proliferate and slough with the menstrual cycle.
- Stage I (minimal) to IV (severe). Staging is useful in therapeutic planning but does not correlate with pain severity.

EPIDEMIOLOGY

Prevalence
- Female only
- Affects 6–10% of fertile women (1)
- Found in 20–50% of infertile women (1)
- Found in 71–87% of women with chronic pelvic pain (1)

Pediatric Considerations
Endometriosis may begin with puberty as endometrial implants are dependent on ovarian hormones. This can lead to debilitating pelvic pain and severe dysmenorrhea associated with missed school, social, and family activities.

Pregnancy Considerations
The presence of endometriosis decreases fecundability from 15–20% per month to 2–10% per month. 25–50% of infertile women have endometriosis. However, pelvic endometriosis generally improves during pregnancy.

Geriatric Considerations
Although menopause often results in a resolution of symptoms, pelvic endometriosis may extend into menopause and may be exacerbated by hormone replacement therapy (HRT).

ETIOLOGY AND PATHOPHYSIOLOGY
- Not fully understood; several factors are believed to play a role, including immunologic changes and genetic predisposition in the presence of abnormal proliferating endometrial tissue implants causing chronic peritoneal inflammation.
- Theories include:
– Sampson theory: Retrograde menstruation results in peritoneal implantation and disease.
– Halban theory: Distant disease is probably caused by hematogenous/lymphatic dissemination or metaplastic transformation.
– Coelomic metaplasia: Coelomic epithelium remains undifferentiated in the peritoneal cavity and differentiates to form functioning endometrium.

Endometrial-associated infertility is multifactorial:
– Pelvic inflammation
– Anatomic disruption of pelvic structures (Involvement of the fallopian tube may cause isthmic tubal obstruction.)
– Proliferation and activation of peritoneal macrophages (may predispose to gamete phagocytosis)
– Alteration in eutopic endometrium

Genetics
Odds ratio of symptomatic endometriosis with a first-degree affected relative is 7.2. Those with affected first-degree relatives have a 26% chance of severe manifestations versus 12% if no first-degree affected relatives.

RISK FACTORS
● Family history
● Menstruation and ovulation
● Delayed childbirth

GENERAL PREVENTION
● Suppression of heavy menstruation and ovulation with oral contraceptives during adolescence may delay sequelae.
● Some factors are considered protective:
  – Fruits, green vegetables, n-3 long-chain fatty acids
  – Aerobic exercise may decrease pelvic pain.
● Early diagnosis and treatment might help prevent sequelae.

COMMONLY ASSOCIATED CONDITIONS
Associated with increased risks for cancer of the ovary, breast, endometrium; increased risk for cutaneous melanoma, non-Hodgkin lymphoma, autoimmune diseases, asthma, and cardiovascular disease

DIAGNOSIS

HISTORY
● Dysmenorrhea (50–90% of cases) due to deep infiltrating endometrial implants
● Dyspareunia due to lesions of the cul-de-sac, uterosacral ligaments, and posterior vaginal fornix
● Dyschezia due to involvement of the rectosigmoid colon and rectovaginal regions
● Chronic pelvic pain (≥6 months) that worsens with time and begins 1 to 2 days prior to menstrual cycles
● Hematochezia
● Cyclic nausea, abdominal distention
- Infertility (late finding)
- History of pelvic pain, infertility, and hysterectomy in first- or second-degree relative

**PHYSICAL EXAM**
- Focal pain/tenderness on pelvic exam is associated with endometriosis in 66% of patients.
- Pelvic mass may be present.
- Immobile pelvic organs (frozen pelvis)
- Rectovaginal exam revealing uterosacral nodules, beading, or tenderness
- An exquisitely tender “barb” stabbing pain in the region of the uterosacral ligament is found in severe cases.

**DIFFERENTIAL DIAGNOSIS**
Differential diagnosis of pelvic pain includes all causes of acute abdomen and
- Pelvic adhesions
- Nonspecific dysmenorrhea
- Acute salpingitis/pelvic inflammatory disease
- Ruptured ovarian cyst
- Uterine leiomyomas
- Adenomyosis
- Irritable bowel syndrome
- Inflammatory bowel disease
- Pelvic malignancy
- Complications of intrauterine/ectopic pregnancy
- Cystitis
- Depression
- History of sexual abuse
- Chronic pain syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Labs are only useful to rule out other diagnoses; there are no useful labs to rule in endometriosis.
- CA-125 levels are not recommended (2)[C] due to low sensitivity.
- If history and physical exam reveal adnexal pain or tenderness with/without fullness on pelvic exam
  - Transvaginal ultrasound (US) and MRI are equally effective in detecting ovarian endometriomas: sensitivity, 80–90%; specificity, 60–98% for both
  - US is preferred (less costly).
  - Both modalities are poor in detecting peritoneal implants and adhesions.

**Diagnostic Procedures/Other**
Definitive diagnosis is made only by microscopic characteristics of tissue biopsied during laparoscopy or laparotomy (1).

**Test Interpretation**
- Laparoscopically visualized red and blue-black lesions described as “powder-burns,” adhesions, and “chocolate cysts” on the ovarian and peritoneal surfaces
- Histologically described endometrial glands and stroma on analysis of biopsied lesions
TREATMENT

GENERAL MEASURES
Management is dependent on multiple factors:
- Age and reproductive desires of the patient
- The certainty of the diagnosis
- The degree of degradation on quality of life due to pain and infertility
- The threat to other organ systems: GI tract, bladder

MEDICATION
Medications are used to improve the patient’s quality of life through symptom relief and to prevent progression of the disease and its potential to cause organ dysfunction. Unfortunately, few studies of medical therapy report patient-relevant outcomes. Many women gain only limited or intermittent benefit from medical therapies (3)[A].

First Line
Women found to have endometriomas during incidental surgery or studies may not need any treatment. Others with minimal symptoms may find sufficient relief with NSAID medications. Increased exercise, especially aerobic, may help others.
- Cyclic combined oral contraceptive pills (OCPs) suppress ovulation.
- NSAIDs initiated at the beginning or just before menses. Evidence is inconclusive on effectiveness (4)[B].

Second Line
- Low-dose OCPs or low-dose progestins with recommendations to switch from cyclic to continuous combined contraception for 3 to 6 months if symptoms persist or if there is chronic, noncyclic pelvic pain (5)[A]. Evidence for combined hormonal contraception is of relatively low quality.
- Levonorgestrel intrauterine device (IUD) (Mirena) found to decrease recurrence of painful menstruation (although not FDA-approved for this indication)
- Medroxyprogesterone acetate 150 mg IM 3 months. Prolonged use may lead to loss of bone mineral density of uncertain clinical significance.
- Gonadotropin-releasing hormone (GnRH) agonists: inhibit pituitary gonadotropin synthesis and induce a hypoestrogenic state
- Norethindrone acetate 5 mg PO once daily plus conjugated equine estrogen 0.625 mg PO once daily

Third Line
If symptoms and signs continue, physicians should be experienced in the use and side effects of GnRH analogues prior to their use (symptoms return in as many as 70% of treated patients):
- Leuprolide acetate (Lupron Depot) 3.75 mg IM each month or 11.25 mg IM every 3 months (gluteal)
- Nafarelin (Synarel) intranasal one spray (200 μg) in one nostril each morning and the other nostril each evening (start between days 2 and 4 of menstrual cycle)
- Goserelin (Zoladex) implant 3.6 mg SC in upper abdominal wall every 28 days
- Danazol: also effective, with side effects similar to GnRH analogs
- Aromatase inhibitors (anastrozole and letrozole) prolong the remission induced by GnRH
medications.

**ALERT**
Calcium (1,000 to 1,500 mg/day) with vitamin D 1,000 to 2,000 IU daily or low-dose estrogen with progestogen (1)[A],(6)[B] is recommended when using GnRH agonists to prevent calcium loss.

**ISSUES FOR REFERRAL**
- Refer early to a physician with expertise in medical and surgical treatment of endometriosis, especially if the patient desires to conceive in the future.
- Indications for referral to a specialty gynecologist include the following:
  - Need for definitive diagnosis
  - Failure to respond to a conservative or first-line therapy
  - Chronic pelvic pain
  - Delayed fertility

**ADDITIONAL THERAPIES**
Regular exercise and counseling for pain-management strategies. Narcotics are contraindicated for chronic pain.

**SURGERY/OTHER PROCEDURES**
Surgery (laparoscopy or laparotomy) is both diagnostic and therapeutic (first line or when conservative measures fail):
- Peritoneal endometriosis: laser ablation/excision/fulguration
- Ovarian endometriosis (endometriomas) >3 to 4 cm: ablation, excision, drainage
- Lysis of adhesions (LOA)
- Hysterectomy with bilateral salpingo-oophorectomy for debilitating symptoms refractory to other medical or surgical treatments:
  - Relieves pain in 80–90%, but pain recurs in 10% within 1 to 2 years after surgery
  - Postoperative HRT should include estrogen and progestogen or progesterone.
- Interruption of nerve pathways: Laparoscopic ablations and presacral neurectomy improve dysmenorrhea.
- Fertility procedures: Ablation or excision of lesions with LOA is recommended to treat infertility in stages I and II disease:
  - Spontaneous conception should be attempted for 1 year prior to assisted reproduction techniques.
  - Disease does not endanger in vitro fertilization (IVF) pregnancies.

**ALERT**
Surgery for endometriomas may decrease ovarian reserve in advanced disease.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Osteopathic manipulative therapy found to improve quality of life (2)[C]
- Postsurgical use of Chinese herbal medicine has been found to be effective.
- Acupuncture may be more effective than danazol to decrease pain, irregular menstruation, and perineal swelling.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Routine gynecologic care

Patient Monitoring
Symptomatic and asymptomatic pelvic masses (http://www.acog.org/)

PROGNOSIS
- Excellent, especially if diagnosis and treatment plans are initiated early in disease course
- Poor for recovery of fertility if the disease has progressed to stage III/IV
- Symptoms and signs improve after bilateral oophorectomy.

COMPLICATIONS
Sequelae include chronic pelvic pain, reduced quality of life, repetitive surgical intervention, depression, medication side effects and costs, and infertility.

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**
- N80.9 Endometriosis, unspecified
- N80.3 Endometriosis of pelvic peritoneum
- N80.2 Endometriosis of fallopian tube

**CLINICAL PEARLS**
- Severe dysmenorrhea and dyspareunia are never normal. Failure to respond to NSAIDs and/or OCPs warrants further investigation.
- A rectovaginal exam can be useful in patients suspected of having endometriosis.
ENDOMETRITIS AND OTHER POSTPARTUM INFECTIONS

Justin P. Lavin Jr., MD ▪ Cassandra Heiselman, DO, MPH ▪ Michelle N. Lende, DO

BASICS

DESCRIPTION
• Endometritis (infection of the endometrium) is the most common postpartum infection.
• Bacterial infection of genital tract, usually within the 1st week after delivery, can occur as late as 1 to 6 weeks postpartum.
• Postpartum infections of the myometrium and parametrial tissues are less common. Vaginal and cervical infections, perianal cellulitis, pelvic cellulitis, septic pelvic vein thrombophlebitis, and parametrial phlegmon are other (generally rare) postpartum infections of the pelvic region.
• System(s) affected: reproductive
• Synonym(s): postpartum infection; endometritis; endoparametritis; endomyometritis; myometritis; endomyoparametritis; metritis; metritis with pelvic cellulitis

EPIDEMIOLOGY

Incidence
Occurs in women of childbearing years

Prevalence
• Occurs after 1–3% of all births
• Infection 10 times more likely after cesarean section
  – 2–15% of infections occur prior to labor.
  – 30–35% occur after labor in absence of appropriate antibiotic prophylaxis; 2–15% occur after labor with appropriate prophylaxis.
  – Fifth leading cause of maternal mortality, accounting for 11% of maternal deaths

ETIOLOGY AND PATHOPHYSIOLOGY
• Endometritis is more common in labors complicated by chorioamnionitis.
• Other infections follow trauma to the perineum, vagina, cervix, and uterus.
• Postpartum infections are typically polymicrobial, involving organisms ascending from the lower genital tract:
  – Aerobic isolates (70%): Streptococcus faecalis, Streptococcus agalactiae, Streptococcus viridans, Staphylococcus aureus, Escherichia coli
  – Anaerobic isolates (80%): Peptococcus sp., Peptostreptococcus sp., Clostridium sp., Bacteroides bivius, Bacteroides fragilis, Fusobacterium sp.
• Other genital Mycoplasma
• Consider herpes simplex virus and cytomegalovirus, particularly in immunocompromised patients failing to improve on appropriate antibiotics.
• Thrombosis of any pelvic vein, including vena cava
• Phlegmon on leaves of the broad ligament
RISK FACTORS
- Cesarean delivery is the primary risk factor.
- Chorioamnionitis
- Bacterial vaginosis
- Group B streptococcal colonization of genital tract
- HIV infection
- Prolonged labor
- Prolonged rupture of membranes; heavily meconium stained amniotic fluid
- Multiple vaginal examinations
- Internal fetal monitoring during labor
- Operative vaginal delivery; manual extraction of the placenta; care in a teaching hospital
- Low socioeconomic status
- Obesity
- Anemia

GENERAL PREVENTION
- Intrapartum prophylaxis for Group B colonization of genital tract
- Vaginal delivery
  - Avoid unnecessary vaginal examinations.
  - Treat chorioamnionitis during labor.
  - Avoid manual placental extraction and retained placental products.
  - Consider antibiotic prophylaxis for third- and fourth-degree laceration
  - Aseptic technique for operative vaginal delivery—consider prophylactic antibiotics
  - Antibiotic prophylaxis for operative vaginal delivery or manual removal of the placenta have not been clearly demonstrated to be effective.
- Cesarean delivery
  - Preoperative paint and scrub with 10% povidone-iodine scrub or an alcohol-based solution decreases puerperal infection by up to 38% (1)[A].
  - Prophylactic antibiotics before both emergency and scheduled cesarean deliveries prior to skin incision reduce postpartum infection (2)[A].
    - Administer antibiotics within 1 hour of the start of surgery (3).
    - Should be repeated for lengthy procedures or excessive blood loss (3)
  - Extended coverage with cephalosporin and Azithromycin further decreases infection risk and is cost effective (3,4)[A].
  - Vaginal preparation with povidone-iodine solution or Chlorhexidine-alcohol solutions immediately before cesarean delivery reduces the risk of postoperative endometritis (5)[A].
  - Weight-based antibiotic dosage helps ensure appropriate tissue concentrations prior to skin incision.
  - Placental removal with gentle traction
  - Use of multiple interventions as a bundle are more effective than individual components

COMMONLY ASSOCIATED CONDITIONS
- Chorioamnionitis
- Wound infection
DIAGNOSIS

HISTORY
- History of cesarean delivery or chorioamnionitis
- Fever and chills
- Malaise
- Headache
- Anorexia
- Abdominal pain
- Heavy vaginal bleeding or foul smelling lochia

PHYSICAL EXAM
- Oral temperature >38°C (100.4°F)
- Tachycardia
- Uterine tenderness on exam (key finding)
- Other localized abdominopelvic tenderness on exam
- Purulent or malodorous lochia
- Heavy vaginal bleeding
- Ileus
- Group A or B streptococcal bacteremia may have no localizing signs.

DIFFERENTIAL DIAGNOSIS
- “5 Ws”: Wind (pneumonia); Water (UTI); Wound infection; Wow (mastitis); Wonder drug (medication-related fever)
- Viral syndrome; dehydration
- Thrombophlebitis
- Thyroid storm
- Appendicitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- CBC: Interpret with care. (Physiologic leukocytosis may be as high as 20,000 WBCs.)
- Two sets of blood cultures (especially with suspected sepsis)
- Diagnosis often made on clinical grounds. Potential testing includes:
  - Genital tract cultures and rapid test for group B streptococci (may be done during labor)
  - Amniotic fluid Gram stain: usually polymicrobial
  - Uterine tissue cultures: Prep the cervix with Betadine and use a shielded specimen collector or Pipelle; difficult to obtain without contamination
- If patient not responding to antibiotics in 24 to 48 hours:
  - Ultrasound for retained products of conception, pelvic abscess, or mass
  - CT or MRI looking for pelvic vein thrombophlebitis, abscess, or deep-seated wound infection

Diagnostic Procedures/Other
Paracentesis/culdocentesis with culture rarely necessary

Test Interpretation
Superficial layer of infected necrotic tissue in microscopic sections of uterine lining
>5 neutrophils per high-power field in superficial endometrium; ≥1 plasma cell in endometrial stroma

TREATMENT

MEDICATION

First Line
Clindamycin 900 mg IV q8h + gentamicin 5 mg/kg IV q24h (6)[A]
- Potential side effects include nephrotoxicity, ototoxicity, pseudomembranous colitis, or diarrhea (in up to 6%).

Second Line
- Ampicillin/sulbactam 3 g IV q6h
- Metronidazole 500 mg IV or PO q8–12h + penicillin 5,000,000 U IV q6h, or
- Ampicillin 2 g IV q6h + gentamicin 5 mg/kg IV q24h (6)[A]
- Cefoxitin 2 g IV q6h. Add ampicillin 2 g IV q6h, if clinical failure after 48 hours (6)[A].
- Cefotetan 2 g IV q12h. Add ampicillin 2 g IV q6h, if clinical failure after 48 hours (6)[A].
- Note: Base therapy on cultures, sensitivities, and clinical response.
- Contraindications
  - Drug allergy
  - Renal failure (aminoglycosides)
  - Avoid sulfa, tetracyclines, and fluoroquinolones before delivery and if breastfeeding.
    Metronidazole is relatively contraindicated if breastfeeding.
- Precautions:
  - Clindamycin and other antibiotics occasionally cause pseudomembranous colitis.
  - Antibiotic-associated diarrhea (Clostridium difficile)
- Note: Consider adding a macrolide antibiotic (for chlamydia coverage) for infections occurring after 48 hours.
- Note: Heparin typically indicated for septic pelvic vein thrombophlebitis; requires 10 days of full anticoagulation

SURGERY/OTHER PROCEDURES
- Curettage for retained products of conception
- Surgery or image-guided drainage to drain abscess
- Surgery to decompress the bowel
- Surgical drainage of a phlegmon is not advised unless it is suppurative. Surgical removal of other inflamed tissue is usually not required.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Inpatient care is recommended for postpartum infections.
- Many infections occur after hospital discharge.
- IV antibiotics and close observation for severe infections
- Open and drain infected wounds.
- Optimize fluid status.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Individualize according to severity.
- IV antibiotics can be stopped when the patient is afebrile for 24 to 48 hours.
- Oral antibiotics on discharge are not necessary, unless patient was bacteremic; then continue oral antibiotics to complete a 7-day course.

DIET
As tolerated, although may be limited by ileus

PATIENT EDUCATION
- Advise patient to contact physician with fever >38°C (100.4°F) postpartum, heavy vaginal bleeding, foul-smelling lochia, or other symptoms of infection.

PROGNOSIS
With supportive therapy and appropriate antibiotics, most patients improve quickly and recover without complication.

COMPLICATIONS
- Resistant organisms; peritonitis; pelvic abscess
- Septic pelvic thrombophlebitis
- Ovarian vein thrombosis
- Sepsis; death

REFERENCES

ADDITIONAL READING

SEE ALSO
Algorithm: Pelvic Pain

CODES

ICD10

- O86.12 Endometritis following delivery
- O86.4 Pyrexia of unknown origin following delivery
- O86.13 Vaginitis following delivery

CLINICAL PEARLS

- Postpartum endometritis follows 1–3% of all births.
- Infections are typically polymicrobial and involve organisms ascending from the lower genital tract.
- Evidence supports antibiotic prophylaxis prior to skin incision for all cesarean deliveries but not for operative vaginal deliveries.
- Clindamycin 900 mg IV q8h and gentamicin 5 mg/kg q24h are recommended as first-line therapy for endometritis. Treat until the patient is afebrile for 24 to 48 hours and stop antibiotics completely (unless there is documented bacteremia, which requires a 7-day course of therapy).
- If no improvement occurs on antibiotics, consider retained placental products, abscess, wound infection, hematoma, cellulitis, phlegmon, or septic pelvic vein thrombosis.
ENURESIS
Joseph L. Hesse, MD ● Swati Avashia, MD, FAAP, FACP, ABIHM

BASICS

DESCRIPTION

Classification

- Primary nocturnal enuresis (NE): 80% of all cases; person who has never established urinary continence on consecutive nights for a period of ≥6 months
- Secondary NE: 20% of cases; resumption of enuresis after at least 6 months of urinary continence

NE: intermittent nocturnal incontinence after the anticipated age of bladder control (age 5 years)

- Primary monosymptomatic NE (PMNE): bed-wetting with no history of bladder dysfunction or other lower urinary tract (LUT) symptoms
- Nonmonosymptomatic NE (NMNE): bed-wetting with LUT symptoms such as frequency, urgency, daytime wetting, hesitancy, straining, weak or intermittent stream, posturination dribbling, lower abdominal or genital discomfort, or sensation of incomplete emptying

ALERT

Adult-onset NE with absent daytime incontinence is a serious symptom; complete urologic evaluation and therapy are warranted.

- System(s) affected: nervous, renal/urologic
- Synonym(s): bed-wetting; sleep enuresis; nocturnal incontinence; primary NE

EPIDEMIOLOGY

Incidence

- Depends on family history
- Spontaneous resolution: 15% per year

Prevalence

- Very common; 5 to 7 million children in the United States (1)
- 10% of 7-year-olds; 3% of 11- to 12-year-olds; 0.5–1.7% at 16 to 17 years old (2)
- 1.5 to 2 times more common in males than females
- Nocturnal > day (3:1)

Geriatric Considerations

Infrequent; often associated with daytime incontinence (formerly referred to as diurnal enuresis)

ETIOLOGY AND PATHOPHYSIOLOGY

- A disorder of sleep arousal, a low nocturnal bladder capacity, and nocturnal polyuria are the three factors that interrelate to cause NE.
- Both functional and organic causes (below); many theories, none absolutely confirmed
- Detrusor instability
- Deficiency of arginine vasopressin (AVP); decreased nocturnal AVP or decreased AVP stimulation secondary to an empty bladder (Bladder distension stimulates AVP.)
- Maturational delay of CNS
- Severe NE with some evidence of interaction between bladder overactivity and brain arousability: association with children with severe NE and frequent cortical arousals in sleep
- Organic urologic causes in 1–4% of enuresis in children: urinary tract infection (UTI), occult spina bifida, ectopic ureter, lazy bladder syndrome, irritable bladder with wide bladder neck, posterior urethral valves, neurologic bladder dysfunction
- Organic nonurologic causes: epilepsy, diabetes mellitus, food allergies, obstructive sleep apnea, chronic renal failure, hyperthyroidism, pinworm infection, sickle cell disease
- NE occurs in all stages of sleep.

**Genetics**
Most commonly, NE is an autosomal-dominant inheritance pattern with high penetrance (90%).
- 1/3 of all cases are sporadic.
- 75% of children with enuresis have a first-degree relative with the condition.
- Higher rates in monozygotic versus dizygotic twins (68% vs. 36%)
- If both parents had NE, risk in child is 77%; 44% if one parent is affected. Parental age of resolution often predicts when child’s enuresis should resolve.

**RISK FACTORS**
- Family history
- Stressors (emotional, environmental) common in secondary enuresis (e.g., divorce, death)
- Constipation and/or encopresis
- Organic disease: 1% of monosymptomatic NE (e.g., urologic and nonurologic causes)
- Psychological disorders
  - Comorbid disorders are highest with secondary NE: depression, anxiety, social phobias, conduct disorder, hyperkinetic syndrome, internalizing disorders.
  - Association with ADHD; more pronounced in ages 9 to 12 years
- Altered mental status or impaired mobility

**GENERAL PREVENTION**
No known measures

**COMMONLY ASSOCIATED CONDITIONS**
- Obstructive sleep apnea syndrome (10–54%) (1): Atrial natriuretic factor inhibits renin-angiotensin-aldosterone pathway leading to diuresis.
- Constipation (33–75%) (1)
- Behavioral problems (specifically ADHD in 12–17%) (1)
- Overactive bladder or dysfunctional voiding (up to 41%) (1)
- UTI (18–60%) (1)

**DIAGNOSIS**

**HISTORY**
- Age of onset, duration, severity
- LUT tract symptoms
- Daily intake patterns
- Voiding and stooling patterns (voiding diary)
Psychosocial history
Family history of enuresis
Investigation and previous treatment history

PHYSICAL EXAM
- ENT: evaluation for adenotonsillar hypertrophy
- Abdomen: enlarged bladder, kidneys, fecal masses, or impaction
- Back: Look for dimpling or tufts of hair on sacrum.
- Genital urinary exam
  - Males: meatal stenosis, hypospadias, epispadias, phimosis
  - Females: vulvitis, vaginitis, labial adhesions, ureterocele at introitus; evidence of abuse
- Rectal exam: tone, fecal soiling, fecal impaction
- Neurologic exam, especially lower extremities

DIFFERENTIAL DIAGNOSIS
- Primary NE
  - Delayed physiologic urinary control
  - UTI (both)
  - Spina bifida occulta
  - Obstructive sleep apnea (both)
  - Idiopathic detrusor instability
  - Previously unrecognized myelopathy or neuropathy (e.g., multiple sclerosis, tethered cord, epilepsy)
  - Anatomic urinary tract abnormality (e.g., ectopic ureter)
- Secondary NE
  - Bladder outlet obstruction
  - Neurologic disease, neurogenic bladder (e.g., spinal cord injury)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Only obligatory test in children is urinalysis.
- Urinalysis and urine culture: UTI, pyuria, hematuria, proteinuria, glycosuria, and poor concentrating ability (low specific gravity) may suggest organic etiology, especially in adults.
- Urinary tract imaging is usually not necessary.
- If abnormal clinical findings or adult onset: renal and bladder US
- IV pyelogram, voiding cystourethrogram (VCUG), or retrograde pyelogram is rarely indicated (1).
- MRI if spinal dysraphism is suspected

Follow-Up Tests & Special Considerations
- Secondary enuresis: serum glucose, BUN, creatinine, thyroid-stimulating hormone (TSH), urine culture
- In children, imaging and urodynamic studies are helpful for significant daytime symptoms, history of UTIs, suspected structural abnormalities, and in refractory cases.

Diagnostic Procedures/Other
Urodynamic studies may be beneficial in adults and nonmonosymptomatic NE.
Test Interpretation
- Dysfunctional voiding
- Detrusor instability and/or reduced bladder capacity most common findings

TREATMENT

GENERAL MEASURES
- Use nonpharmacologic approaches as first line before prescribing medications (1)[A].
- Simple behavioral interventions (e.g., scheduled wakening, positive reinforcement, bladder training, diet changes) are effective, although less so than alarms or medications (1)[B]; found to achieve dryness in 15–20% of cases (3)
  - Explain the three pathophysiologic factors (fragmented sleep, low nocturnal bladder capacity, and increased nocturnal urine production).
  - Encourage normal drinking patterns during daytime hours and reduction of intake 2 hours prior to sleep.
  - Emphasize regular bedtime with full night’s sleep.
  - Scheduled voiding before bed
  - Scheduled waking for nighttime voiding
  - Nightlights to light the way to the bathroom
  - Reward system for dry nights
  - Use pull up over regular underwear or cloth underwear with built in waterproof barrier.
  - “Cleanliness training”: child helps with changing wet bedding
- Do not shame or punish bed-wetting but have the child participate in removing and laundering soiled bedding and garments.
- If behavioral interventions alone have no success, combined therapy (e.g., enuresis alarm, bladder training, motivational therapy, and pelvic floor muscle training) is more effective than each component alone or than pharmacotherapy (1)[A].
- Enuresis alarms (bells or buzzers)
  - Considered first line; most effective treatment
  - 66–70% success rate; must be used nightly for 2 to 4 months; offers cure; significant parental involvement; disruption of sleep for entire family
  - If successful, it should be used until 14 consecutive dry nights achieved (2)[B].
- See “Patient Education” for options.

MEDICATION
First Line
Desmopressin (DDAVP): synthetic analogue of vasopressin that decreases nocturnal urine output (2)[A]
- Intranasal DDAVP: adults only, 20 mg (2 sprays) intranasally at bedtime
- FDA recommends against use in children due to reports of severe hyponatremia resulting in seizures and deaths in children using intranasal formulations of desmopressin.
- Oral DDAVP: safe in children. Begin at 0.2 mg tablet taken at bedtime on empty stomach; after 14 days of inefficient treatment, can titrate to 0.4 mg (2).
  - Maximally effective in 1 hour; effect lasts 8 to 10 hours.
  - If treatment is successful, can be continued for 3 months, then stop for 2 weeks for test of
dryness.
– High relapse rate after discontinuation without a structured withdrawal program. If relapse occurs, oral desmopressin can continue to be prescribed in 3-month blocks.
– Suspend dose in children who experience acute condition affecting fluid/electrolyte balances (fever, vomiting, diarrhea, vigorous exercise).
– 60–70% success; 30% of children have full response and 40% have partial response.

**Pediatric Considerations**
FDA recommends against using intranasal formulations of desmopressin in children due to reports of severe hyponatremia resulting in seizures and deaths (3)[A].

**Second Line**

- **Imipramine (Tofranil):** tricyclic antidepressant, anticholinergic effects; increases bladder capacity, antispasmodic properties
  – Primarily in adults; use in children is reserved for resistant cases and initiated by specialists.
  – Dose: adults, 25 to 75 mg and children >6 years, 10 to 25 mg PO at bedtime; increase by 10 to 25 mg at 1- to 2-week intervals; treat for 2 to 3 months; then taper.
  – 40% success rate, but relapses after discontinuation are high (2).
  – Pretreatment ECG recommended identifying underlying rhythm disorders.

- **Anticholinergics: Monotherapy is not recommended in children.**
  – Oxybutynin (Ditropan, Ditropan XL, Oxytrol patch): anticholinergic; smooth muscle relaxant, antispasmodic; may increase functional bladder capacity and aids in timed voiding (4)[B]
    - 30–50% success; 50% relapse after stopped
    - Ditropan: adults: 5 mg PO TID–QID; children >5 years old with overactive bladder who have failed alarm therapy and desmopressin can try 5 mg at bedtime.
    - Ditropan XL: adults: 5 mg/day PO; increase to 30 mg/day PO (5- to 10-mg tablet).
    - Oxytrol patch: 1 patch every 3 to 4 days (3.9 mg/patch) (Periodic trials of the medication, that is, weekends or weeks at a time, will help determine efficacy and resolution of primary disturbance.)
  – Tolterodine (Detrol, Detrol LA): anticholinergic; fewer side effects than Ditropan (4)[B]
    - Detrol: 1 to 2 mg PO BID in adults, 2 mg at bedtime in children >5 years old
    - Detrol LA: 2 to 4 mg/day

- **Precautions**
  – Oxybutynin: glaucoma, myasthenia gravis, GI or genitourinary obstruction, ulcerative colitis, constipation, megacolon; use a decreased dose in the elderly.
  – Tolterodine: urinary retention, gastric retention, constipation, uncontrolled narrow-angle glaucoma; significant drug interactions with CYP2D6, CYP3A3/4 substrates
  – Desmopressin: Avoid in patients at risk for electrolyte changes or fluid retention (congestive heart failure [CHF], renal insufficiency). Stop during gastroenteritis or other acute illness with risk of dehydration.
  – Imipramine: Do not use with monoamine oxidase inhibitors (MAOIs), hypotension, and arrhythmias; low-toxic therapeutic ratio

- **Combination therapy with DDAVP and oxybutynin has better results than individual use (4) [B].**

**ALERT**
ISSUES FOR REFERRAL
- Primary NE: persistent enuresis despite nonpharmacologic and pharmacologic therapies
- Diurnal incontinence or nonmonosymptomatic enuresis with voiding dysfunction or underlying medical condition

ADDITIONAL THERAPIES
Individual and family psychotherapy, crisis intervention

SURGERY/OTHER PROCEDURES
Only for surgically correctable causes (e.g., tethered cord, ectopic ureter, benign prostatic hypertrophy, obstructive sleep apnea)

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture has small amounts of supportive data (3)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- When starting with nonpharmacologic treatment, patient should be seen in clinic every 1 to 3 months.
- If starting enuresis alarm, patient should return in 1 week to assess response.
- If starting DDAVP, patient should return in 1 to 2 weeks to assess response and then return at least every 3 months.

DIET
- Limit fluid and caffeine intake 2 hours before sleep.
- Limit dairy products 4 hours before sleep (decrease osmotic diuresis) (5).

PATIENT EDUCATION
Web resources for hypnosis scripts, alarms, and supplies
- www.hypnoticworld.com/hypnosis-scripts/habits-disorders/enuresis
- http://wetstop.com
- https://bedwettingstore.com
- www.dri-sleeper.com
- www.nitetrain-r.com
- Parents can search their App Store for free bed-wetting diary apps (e.g., My Dryness Tracker).

PROGNOSIS
In children, NE is usually self-limiting; 1% will persist as adult; evaluate for organic causes.

COMPLICATIONS
UTI, perineal excoriation, psychological disturbance (especially in children)

REFERENCES

SEE ALSO
- Incontinence, Urinary Adult Female; Incontinence, Urinary Adult Male
- Algorithm: Enuresis, Secondary

CODES

ICD10
- N39.44 Nocturnal enuresis
- R32 Unspecified urinary incontinence
- F98.0 Enuresis not due to a substance or known physiol condition

CLINICAL PEARLS
- Initial evaluation is history, exam, and urinalysis.
- For PMNE in children, if the condition is not distressing to child and caretakers, treatment is unnecessary.
- Behavioral and lifestyle interventions are the first-line treatment for PMNE; alarms and desmopressin are the most effective treatments.
- Dryness is possible for most children.
EPICONDYLITIS
Julie A. Creech, DO ▪ Brooke E. Organ, DO ▪ Sabrina L. Silver, DO, CAQSM

BASICS

DESCRIPTION
- Tendinopathy of the elbow characterized by pain and tenderness at the origins of the wrist flexors/extensors at the humeral epicondyles
- May be acute (traumatic) or chronic (overuse)
- Two types
  - Medial epicondylitis (ME, “golfer’s elbow”)
    - Involves the wrist flexors and pronators, which originate at the medial epicondyle
  - Lateral epicondylitis (LE, “tennis elbow”)
    - Involves the wrist extensors and supinators, which originate at the lateral epicondyle
- May be caused by various different athletic or occupational activities
- Common in carpenters, plumbers, gardeners, and overhead athletes
- 75% of cases involve the dominant arm.

EPIDEMIOLOGY
- Predominant age: >40 years
- Predominant sex: male = female

Incidence
- Common overuse injury
- Lateral > medial
- Estimated between 1% and 3%

Prevalence
- LE: 1.3%
- ME: 0.4%

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute (tendonitis)
  - Inflammatory response to injury or sudden, violent contraction
- Chronic (tendinosis)
  - Overuse injury
  - Repetitive wrist flexion or extension places strain across enthesis of flexor/extensor group.
  - Degeneration, calcium deposition, fibroblast proliferation, microvascular proliferation, hyaline cartilage destruction, absence of restorative inflammatory response
- Aggravating activities
  - Tool/racquet gripping
  - Shaking hands
  - Occupational (painters, mechanics, cooks)
  - Sports (golf, tennis, archery, pitchers)
RISK FACTORS
- Repetitive wrist motions
  - Flexion/pronation: medial
  - Extension/supination: lateral
- Smoking
- Obesity
- Upper extremity forceful activities

GENERAL PREVENTION
- Limit overuse of the wrist flexors, extensors, pronators, and supinators.
- Use proper techniques when working with hand tools or playing racquet sports.
- Use lighter tools and smaller grips.

DIAGNOSIS

HISTORY
- Insidious onset
- Pain localized to lateral or medial elbow
- Aching pain, often radiates from epicondyle to forearm or wrist
- Pain with gripping
- Sensation of mild forearm weakness

PHYSICAL EXAM
- Localized pain just distal to the affected epicondyle
  - ME
    - Tenderness at origin of wrist flexor tendons
    - Increased pain with resisted wrist flexion and pronation
    - Normal elbow range of motion
    - Increased pain with gripping
  - LE
    - Tenderness at origin of wrist extensors
    - Increased pain with resisted wrist extension/supination
    - Normal elbow range of motion
    - Increased pain with gripping

DIFFERENTIAL DIAGNOSIS
- Elbow osteoarthritis
- Epicondylar fractures
- Posterior interosseous nerve entrapment (lateral)
- Ulnar neuropathy (medial)
- Synovitis
- Medial collateral ligament injury
- Referred pain from shoulder or neck

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
No imaging is required for initial evaluation and treatment of a classic overuse injury.
Follow-Up Tests & Special Considerations

- Anterior-posterior/lateral radiographs if decreased range of motion, trauma, or no improvement with initial conservative therapy. Assess for fractures or signs of arthritis.
- For recalcitrant cases
  - Musculoskeletal ultrasound (US) reveals abnormal tendon appearance (e.g., hypoechoic, tendon thickening, partial tear at tendon origin, calcifications). US can also guide injections of steroid and/or anesthetic.
  - MRI can show intermediate or high T2 signal intensity within the common flexor or extensor tendon or the presence of peritendinous soft tissue edema.

Diagnostic Procedures/Other

Infiltration of local anesthetic with subsequent resolution of symptoms supports the diagnosis if clinically in doubt.

TREATMENT

GENERAL MEASURES

Initial treatment consists of activity modification, counterforce bracing, oral or topical NSAIDs, ice, and physical therapy.

- If left untreated, symptoms typically last between 6 months and 2 years. For patients with good function and minimal pain, consider conservative management using a “wait and see” approach based on patient preference.
- Modify activity, encourage relative rest, and correct faulty biomechanics.
- Bracing
  - Wrist extensor splints (WESs) inhibit contraction of extensor muscle and decreases tendon movement, thereby decreasing stress at the common extensor origin in LE (1)[B].
  - Counterforce bracing with a forearm strap is easy and inexpensive. Systematic reviews are inconclusive about overall efficacy, but initial bracing may improve the ability to perform daily activities in the first 6 weeks.
  - Consider cock-up wrist splinting for repetitive daily activities if counterforce bracing fails; can also use at nighttime to provide relative rest
- Ice frequently after activities
- Physical therapy
  - Begin once acute pain is resolved. Infiltration of local anesthetic can reduce pain and permit better participation in physical therapy.
  - Eccentric strength training and stretching program
  - US therapy
  - Corticosteroid iontophoresis
  - Dry needling

MEDICATION

First Line

- Topical NSAIDs: Low-quality evidence suggests topical NSAIDS are significantly more effective than placebo with respect to pain and number needed to treat to benefit (NNT = 7) in the short term (up to 4 weeks) with minimal adverse effects (2)[A].
- Oral NSAIDs: unclear efficacy with respect to pain and function, but may offer short-term pain
relief; associated with adverse GI effects (2)[A]

Second Line
Corticosteroid injections: short-term (≤ 8 weeks) reduction in pain. No benefits found for intermediate or long-term outcomes (3)[A].

ISSUES FOR REFERRAL
Failure of conservative therapy

ADDITIONAL THERAPIES
Given the mechanism of injury, many new treatments are targeted at tendon regeneration.

- Glyceryl trinitrate (GTN) transdermal patch
  - Nitric oxide (NO) is a small free radical generated by NO synthesis. NO is expressed by fibroblasts and is postulated to aid in collagen synthesis. Topical application of GTN theoretically improves healing by this mechanism. 1/4 of a 5-mg/24-hr GTN transdermal patch is applied once daily for up to 24 weeks.
  - Significant decreases in pain are seen at 3 weeks and 6 months compared to placebo patch.
- Extracorporeal shock wave therapy (ESWT) is a noninvasive, nonelectrical therapy found to be 89% effective in treating LE in some studies and is noted to be as effective as WES (1)[B].
- Prolotherapy
  - Injection of a dextrose solution into and around the tendon attachment stimulates a localized inflammatory response, leading to increased blood flow to stimulate healing.
- Platelet-rich plasma (PRP) injections
  - Injection of supraphysiologic autologous PRP leads to a local inflammatory response. Platelets degranulate, release growth factors, and stimulate the physiologic healing cascade.
  - PRP treatment of chronic LE significantly reduces pain and increases function. The benefit exceeds that of corticosteroid injection even after a follow-up of 1 year (4)[A].
- US-guided percutaneous needle tenotomy
  - Injection of a local anesthetic followed by US-guided tendon fenestration, aspiration, and abrasion of the underlying bone; thought to break apart scar tissue and stimulate inflammation and healing
  - Usually requires referral to sports medicine or orthopedic physician with specific equipment and training.
- Autologous tenocyte injection (ATI)
  - Two-step process
  - Small number of tenocytes are harvested, often from patellar tendon, and cultured.
  - Cultured tenocytes are then injected into tendon to help stimulate regeneration.
- Botulinum toxin A for chronic LE
  - Injections into the forearm extensor muscles (60 units) can be performed in the outpatient setting.

SURGERY/OTHER PROCEDURES
- Surgical intervention required in only 2.8% of patients
- Elbow surgery may be indicated in refractory cases:
  - Involves débridement and tendon release
  - Can be performed open or arthroscopically
  - Improvements in VAS, DASH scores, and grip strength seen in 5-year study (5)[B]
- Denervation of the lateral humeral epicondyle
– Transection of the posterior cutaneous nerve of the forearm with implantation into the triceps may help with chronic symptoms and pain.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Acupuncture: effective for short-term pain relief for lateral epicondyle pain

**ONGOING CARE**

**PROGNOSIS**
Good: Majority resolve with conservative care.

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**
Algorithm: Pain in Upper Extremity

CODES

ICD10
- M77.00 Medial epicondylitis, unspecified elbow
- M77.10 Lateral epicondylitis, unspecified elbow
- M77.01 Medial epicondylitis, right elbow

CLINICAL PEARLS
- ME (golfer’s elbow) is characterized by pain and tenderness at the tendinous origins of the wrist flexors at the medial epicondyle.
- LE (tennis elbow) is characterized by pain and tenderness at the tendinous origins of the wrist extensors at the lateral epicondyle.
- Left untreated, symptoms typically last between 6 months and 2 years
- Most patients improve using conservative treatment with bracing, activity modification, and physical therapy.
- Newer therapies such as ATI, prolotherapy, and tenotomy are directed toward tendon regeneration.
EPIDIDYMITIS
Brittney Benjamin, MD ● Holly L. Baab, MD

BASICS

DESCRIPTION
- Inflammation (infectious or noninfectious) of epididymis resulting in scrotal pain and swelling, induration of the posterior epididymis, eventual scrotal wall edema, involvement of the adjacent testicle, and hydrocele formation
- Acute epididymitis: scrotal pain for <6 weeks
- Chronic epididymitis: scrotal pain for ≥6 weeks
- Epididymitis with involvement of testis is named epididymo-orchitis.
- Classification: infectious (bacterial, viral, fungal, parasitic) vs. noninfectious (chemical, traumatic, autoimmune, idiopathic, industrial, noninfectious, vasoepididymal reflux syndrome, vasal reflux syndrome); chronic vs. acute
- System(s) affected: reproductive

EPIDEMIOLOGY
- Predominant age: usually younger, sexually active men or older men with UTIs; in older men, commonly secondary to bladder outlet obstruction
- Predominant sex: male only

Pediatric Considerations
In prepubertal boys: Epididymitis is found to be the most common cause of acute scrotum—more common than testicular torsion.

Incidence
- Common (600,000 cases annually in the United States) (1)
- 1 in 1,000 adult males per year
- 1.2 in 1,000 boys age 2 to 13 years per year (2,3)

Prevalence
Common

ETIOLOGY AND PATHOPHYSIOLOGY
- Infectious epididymitis
  - Retrograde passage of urinary bacteria from the prostate or urethra to the epididymis via the ejaculatory ducts and the vas deferens, rarely, hematogenous spread
  - Causative organism is identified in 80% of patients and varies according to patient age.
- Noninfectious epididymitis
  - Often no etiology is found; however, can be instigated by trauma, autoimmune disease, or vasculitis
  - Thought to likely be secondary to reflux of sterile urine causing a chemical inflammation rather than infectious
  - Can develop as a sequelae of strenuous exercise with a full bladder when urine is pushed through internal urethral sphincter (located at proximal end of prostatic urethra) or
prolonged periods of sitting

– Reflux of urine through orifice of ejaculatory ducts at verumontanum may occur with history of urethritis/prostatitis because inflammation may produce rigidity in musculature surrounding orifice to ejaculatory ducts, holding them open.

– Exposure of epididymis to foreign fluid may produce inflammatory reaction within 24 hours.

• <14 years of age
  – Cause largely unknown, although likely from anatomic abnormalities resulting in urine reflux such as vesicoureteral reflux, ectopic ureter, or anorectal malformation (rectourethral fistula)
  – May also be part of postinfectious syndrome from Mycoplasma pneumoniae, enterovirus, or adenovirus
  – Henoch-Schönlein purpura may present as acute scrotum.

• 14 to 35 years of age
  – Usually Chlamydia trachomatis (serous urethral discharge) or Neisseria gonorrhoeae (purulent discharge) in sexually active males
  – With anal intercourse, likely Escherichia coli or Haemophilus influenzae

• >35 years
  – Commonly enteric bacteria but occasionally Staphylococcus aureus or Staphylococcus epidermidis
  – In elderly men, often with distal urinary tract obstruction, benign prostatic hyperplasia (BPH), UTI, or catheterization
  – Tuberculosis (TB), if sterile pyuria, nodularity of vas deferens (hematogenous spread), and recent infection. TB is the most common granulomatous disease affecting the epididymitis (4).
  – Sterile urine reflux after transurethral prostatectomy
  – Granulomatous reaction following BCG intravesical therapy for bladder cancer

• Amiodarone may cause noninfectious epididymitis; resolves with decreasing drug dosage

• Syphilis, blastomycosis, coccidioidomycosis, and cryptococcosis are rare causes, but brucellosis can be a common cause in endemic areas.

RISK FACTORS

• UTI
• Prostatitis
• Indwelling urethral catheter
• Urethral instrumentation or transurethral surgery
• Urethral or meatal stricture
• Transrectal prostate biopsy
• Prostate brachytherapy (seeds) for prostate cancer
• Anal intercourse
• High-risk sexual activity
• Strenuous physical activity
• Prolonged sedentary periods
• Bladder obstruction (BPH, prostate cancer)
• HIV-immunosuppressed patient
• Severe Behçet disease
• Presence of foreskin
• Constipation
• Increased intra-abdominal pressure (due to frequent physical strain)
  – Military recruits, especially who begin physically unprepared
  – Laborers; restaurant kitchen workers
  – Full bladder during intense physical exertion

**GENERAL PREVENTION**
• Safer sexual practices
• Mumps vaccination
• Antibiotic prophylaxis for urethral manipulation
• Early treatment of prostatitis/BPH
• Vasectomy or vasoligation during transurethral surgery
• Avoid vigorous rectal exam with acute prostatitis.
• Emptying the bladder prior to physical exertion
• Physically conditioning the body prior to engaging in regular intense physical exertion
• Treat constipation.

**COMMONLY ASSOCIATED CONDITIONS**
• Prostatitis/urethritis/orchitis
• Hemospermia
• Constipation
• UTI

**DIAGNOSIS**

**HISTORY**
• Gradual onset of scrotal pain, sometimes radiating to the groin region over 1 to 2 days
• Urethral discharge or symptoms of UTI, such as frequency of urination, dysuria, cloudy urine, or hematuria
• Detailed sexual history, especially new exposures
• Fever only in 11–19% (3)
• Progresses from the posterior-lying epididymis to the body/head of epididymis
• Entire hemiscrotum becoming swollen and red; the testis becomes indistinguishable from the epididymis; the scrotal wall becomes thick and indurated; and reactive hydrocele may occur.
• Noninfectious epididymitis
  – Unilateral scrotal pain/swelling preceded by prolonged intense physical exertion with full bladder
  – No symptoms of infection

**Pediatric Considerations**
• Bacteremia from H. influenzae infection may produce acute epididymitis.
• Must rule out testicular torsion in adolescent males particularly age >13 years.
• History not helpful in distinguishing epididymitis from testicular torsion

**Geriatric Considerations**
Diabetics with sensory neuropathy may have no pain despite severe infection/abscess.
PHYSICAL EXAM
- Epididymis is markedly tender to palpation.
- The tail of the epididymis is larger in comparison with the contralateral side.
- Elevation of the testes/epididymis reduces the discomfort (Prehn sign).
- Absence of a cremasteric reflex should raise suspicion for testicular torsion.

DIFFERENTIAL DIAGNOSIS
- Testicular/testicular appendage torsion
- Urethritis/orchitis
- Testicular trauma
- Epididymal congestion following vasectomy
- Testicular malignancy
- Epididymal cyst
- Inguinal hernia
- Spermatocele
- Hydrocele
- Hematocele
- Varicocele
- Epididymal adenomatoid tumor
- Epididymal rhabdomyosarcoma
- Vasculitis (Henoch-Schönlein purpura)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- All suspected cases should be evaluated for objective evidence of inflammation by one of the following:
  - Urinalysis/urine culture preferably on first-void urine to evaluate for positive leukocyte esterase and bacteriuria
  - Urine culture/Gram stain urethral discharge; ≥2 WBC per oil immersion field; evaluate for gonococcal infection.
  - Microscopic examination of sediment from a spun first-void urine with ≥10 WBC per high power field
- Urine GC/CT testing for all suspected cases (4)[A]
- CRP >24 mg/L suggestive of epididymitis (5)[C]
- A clear urinalysis and negative culture suggests noninfectious epididymitis
- If testicular torsion/mass cannot be excluded (especially in children), Doppler ultrasound (US) is test of choice (2,3).
- In adult men, US: sensitivity and specificity of 100% in evaluation of acute scrotum (6) compared to sensitivity of 63.6–100% and specificity of 97–100% in children (3)

Pediatric Considerations
Further radiographic imaging in children should be done to rule out anatomic abnormalities.

Diagnostic Procedures/Other
This is a clinical diagnosis.
TREATMENT

GENERAL MEASURES
- Bed rest or restriction on activity
- Scrotal elevation, athletic scrotal supporter
- Ice pack wrapped in towel
- Avoid constipation.
- Spermatic cord block with local anesthesia in severe cases
- If noninfectious epididymitis:
  - No strenuous physical activity and avoidance of any Valsalva maneuvers for several weeks
  - Empty bladder prior to strenuous exercises.

MEDICATION

First Line
- Sexually active adults <35 years: doxycycline 100 mg PO BID for 10 days (C. trachomatis coverage) PLUS ceftriaxone 250 mg IM × 1 (N. gonorrhoeae coverage). Treat all sexual partners within last 60 days (2)[C],(4)[A]
- ≥35 years, not suspecting STD with enteric etiology (i.e., bacteriuria due to bladder outlet obstruction, prostate biopsy, urinary instrumentation, systemic disease, and/or immunosuppression)
  - Levofoxacin 500 mg/day PO for 10 days or
  - Ofloxacin 300 mg PO BID for 10 days (2)[C],(4)[A]
  - Note: 2016 FDA black box warning on fluoroquinolones due to disabling and potentially permanent side effects. Consider trimethoprim-sulfamethoxazole for milder infections.
- Men who practice insertive anal intercourse: ceftriaxone 250 mg IM × 1 plus fluoroquinolone as above. If HIV positive, usually no difference in treatment (2)[C],(4)[A].
- Analgesia:
  - NSAIDs (e.g., naproxen or ibuprofen) for mild to moderate pain
  - Consider steroid if patient cannot tolerate NSAID.
  - Acetaminophen with codeine or oxycodone for moderate to severe pain
- Septic or toxic patient
  - 3rd-generation cephalosporin or aminoglycoside
- For Behçet, sarcoid, Henoch-Schönlein purpura
  - Steroids, such as methylprednisolone, 40 mg/day recommended
- Chronic epididymitis: 2-week course of NSAIDs, scrotal icing/elevation; if no improvement, may add TCA or neuroleptic (2)

Second Line
- Trimethoprim-sulfamethoxazole (Bactrim, Septra) double strength PO BID for 10 to 14 days; increasing bacterial resistance may limit effectiveness.
- Add rifampin (rifampicin) or vancomycin, as required.

Pediatric Considerations
- May be postinfectious inflammatory condition; treat with anti-inflammatories and analgesics.
- Antibiotic therapy can be reserved for young infants until positive urine cultures (2).

ISSUES FOR REFERRAL
If suspicion is high for testicular torsion, then urgent referral to urologist for possible surgery (1)[C]

Epididymitis in ages <14 years requires a urology referral due to high incidence of associated urogenital abnormalities.

If medical management fails, should be referred to urologist to rule out anatomic abnormality or chemical epididymitis

If HIV positive, CMV, salmonella, toxoplasmosis, Ureaplasma urealyticum, Corynebacterium sp., Mycoplasma sp., and Mima polymorpha must also be considered.

SURGERY/OTHER PROCEDURES

- Vasostomy to drain infected material if severe or refractory case
- Scrotal exploration if unable clinically to distinguish between epididymitis and testicular torsion
- Drainage of abscesses, epididymectomy (acute suppurative), or epididymo-orchiectomy in severe cases refractory to antibiotics
- Surgery to correct underlying anatomic abnormality or obstruction

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Intractable pain
- Sepsis
- Abscess
- Persistent vomiting
- Scheduled surgery
- Purulent drainage
- Most cases can be managed with outpatient care.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Routine follow-up in 1 week. Follow up within 72 hours if symptoms fail to improve with treatment for reevaluation of diagnosis and therapy (4)[A].
- Swelling and tenderness after antibiotic course should be evaluated for abscess, tumor, infarction, cancer, TB, and fungal epididymitis (4)[A].
- In noninfectious epididymitis, follow up in 4 weeks to assess efficacy of NSAIDs and lifestyle changes.

DIET

If constipation is contributing to pain or chemical epididymitis, then consider constipation prevention (high-fiber diet) and/or treatment.

PATIENT EDUCATION

- Stress completing course of antibiotics, even when asymptomatic.
- Early recognition and treatment of UTI or prostatitis
- Safer sexual practices. Avoid sex until antibiotic course completed and partner treated if likely STD.
If treated for STI, refer sexual partners for evaluation of N. gonorrhoeae or C. trachomatis if sexual contact within 60 days preceding onset of symptoms or most recent sexual partner if >60 days (4)[A].

If noninfectious epididymitis, then educate on noninfectious etiology and proper lifestyle changes.

PROGNOSIS
- Pain improves within 1 to 3 days, but induration may take several weeks/months to completely resolve.
- If bilateral involvement, sterility may result.
- In noninfectious epididymitis, symptoms usually resolve in <1 week.

COMPLICATIONS
- Recurrent epididymitis
- Infertility
- Oligospermia
- Testicular necrosis or atrophy
- Secondary abscess formation
- Fournier gangrene (necrotizing synergistic infection)

REFERENCES

ADDITIONAL READING
CODES

ICD10
- N45.1 Epididymitis
- N45.3 Epididymo-orchitis
- N45.4 Abscess of epididymis or testis

CLINICAL PEARLS
- With epididymitis, pain is gradual in onset, and the tenderness is mostly posterior to the testis. With testicular torsion, the symptoms are quite rapid in onset, the testis will be higher in the scrotum and may have a transverse lie, and the cremasteric reflex will be absent. The absence of leukocytes on urine analysis and decreased blood flow on scrotal US with Doppler will suggest torsion.
- Prostatic massage is contraindicated in epididymitis because of the risk for worsening local infection. The potential for sepsis is increased with acute prostatitis.
- Noninfectious epididymitis is a clinical diagnosis of exclusion, and infectious causes are much more common but must be considered in certain occupations, such as soldiers and laborers.
EPISCLERITIS
Daniel J. Schlegel, MD, MHA

BASICS
- Episcleritis is irritation and inflammation of the episclera, a thin layer of tissue covering the sclera. It is not an infection.
- Episcleritis is the localized inflammation of the vascular connective tissue superficial to the sclera.
- Usually a self-limited condition, typically resolving within 3 weeks
- Most cases resolve without treatment.
- Topical lubricants and/or topical corticosteroid treatment may relieve symptoms while awaiting spontaneous resolution.

DESCRIPTION
- Edema and injection confined to the episcleral tissue
- Two types
  - Simple (diffuse scleral involvement—more common)
  - Nodular (focal area[s] of involvement—less common)

EPIDEMIOLOGY
Slight female predominance (~60–65%)

Incidence
- May occur at any age
- Peak incidence in 40s to 50s
- Community incidence not well-known (~20 to 50 cases per 100,000 person-years)

Prevalence
Not historically well-known; a recent community study found a prevalence of 53 cases per 100,000 persons.

ETIOLOGY AND PATHOPHYSIOLOGY
- Etiology: usually idiopathic, but other causes may be found (either nonimmune or immune)
- Pathophysiology:
  - Nonimmune (e.g., dry eye syndrome, with histology showing widespread vasodilation, edema, lymphocytic infiltration)
  - Immune (systemic vasculitis or rheumatologic disease)

COMMONLY ASSOCIATED CONDITIONS
- Usually not associated with another condition
- Less commonly associated conditions include the following:
  - Rheumatoid arthritis
  - Vasculitis
  - Inflammatory bowel disease
  - Ankylosing spondylitis
  - Systemic lupus erythematosus
– Gout
– Herpes zoster
– Hypersensitivity disorders
  – Rosacea
  – Contact dermatitis
  – Penicillin sensitivity
  – Erythema multiforme

**DIAGNOSIS**
Episcleritis is a clinical diagnosis (1,2)[C].

**HISTORY**
- History should elicit potential causative factors, recurrence, or associated systemic disease (2).
- Pain is often absent; when present, it is usually mild and localized to the eye (1,2).
- Mild tearing may be present (2).

**PHYSICAL EXAM**
- Check visual acuity; decreased vision is very unusual with episcleritis, and its presence should raise suspicion for another condition such as scleritis (1,2).
- The white sclera will have a pink or purplish hue.
- Focal hyperemia (2,3)
- Pupils equal and reactive (2)
- Superficial episcleral vascular dilation (1,2)
- Episcleral edema (1,2)
  – Diffuse in simple episcleritis
  – Focal in nodular episcleritis
- Tenderness over involved area may be present (2) but is usually absent (3).
- Superficial episcleral vascular hyperemia blanches with topical phenylephrine (1,3).

**ALERT**
Recurrent episodes, difficulty confirming the diagnosis, or worsening symptoms should prompt an ophthalmology referral

**DIFFERENTIAL DIAGNOSIS**
- Scleritis
- Bacterial conjunctivitis
- Viral conjunctivitis
- Herpes (ulcerative) keratitis
- Superficial keratitis
- Increased intraocular pressure (ocular hypertension)

**DIAGNOSTIC TESTS & INTERPRETATION**
Most patients with episcleritis do not require any further lab work or diagnostic studies (4)[C].

**TREATMENT**
MEDICATION
Treatment for episcleritis typically consists of symptomatic relief. The goal is to suppress the inflammation, which will, in turn, relieve the discomfort or pain. In most cases, treatment is not needed.

First Line
Topical lubricants such as artificial tears are typically used for initial management of symptomatic episcleritis (2)[C].

Second Line
- Topical corticosteroids are useful when discomfort is not sufficiently controlled by conservative measures (2,4,5)[C].
  - Flurometholone 0.1% drops 4 times daily; if not effective, may increase frequency
  - Prednisolone 0.5–1% eye drops
- Refractory episcleritis may be treated with oral nonsteroidal anti-inflammatory drugs (NSAIDs) (4)[C].

ISSUES FOR REFERRAL
Recurrent episodes, uncertain diagnosis, and/or worsening symptoms should prompt ophthalmology referral. Rarely, episcleritis may progress to scleritis, in which case ophthalmology referral is also recommended.

ADDITIONAL THERAPIES
- Topical NSAIDs have not been shown to have a significant benefit over artificial tears (6)[B].
- When episcleritis results from viral infection, appropriate antiviral therapy is indicated (5)[C].

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Episcleritis is usually self-limited (up to 21 days) and does not typically require follow-up.

PROGNOSIS
- Most patients have no ocular complications.
- Prognosis for episcleritis is excellent, with most patients making a full recovery.

COMPLICATIONS
Associated complications are rare, even at tertiary care referral centers, where referral bias likely overestimates their community incidence. When complications do occur, they tend not to be severe.
- Anterior uveitis may occur in 4–16% of cases (1,5)[C].
- Decreased vision may occur in 0–4% of cases (1,5)[C].
- Ocular hypertension has been reported in 0–3.5% of cases (1,5)[C].

REFERENCES

ADDITIONAL READING

CODES
ICD10
- H15.109 Unspecified episcleritis, unspecified eye
- H15.129 Nodular episcleritis, unspecified eye
- H15.102 Unspecified episcleritis, left eye

CLINICAL PEARLS
- Episcleritis typically is a benign, self-limited disorder, usually resolving within 3 weeks of symptom onset.
- Often not painful and presents without decrease in visual acuity
- Although treatment is often not needed, when employed, the goal is symptomatic relief while awaiting spontaneous resolution.
- Topical lubricants and/or topical corticosteroid treatment may relieve symptoms.
- Associated complications are uncommon and not severe but may include anterior uveitis, decreased vision, and ocular hypertension.
- Episcleritis can be an early presentation of scleritis, which is more severe. Accurate diagnosis of episcleritis is important.
EPISTAXIS
Rebecca Wetzel, DO ● Brian E. Neubauer, MD

BASICS

DESCRIPTION
- Hemorrhage from the nose involving either the anterior or posterior mucosal surfaces
- Intractable or refractory epistaxis: recurrent or persistent despite appropriate packing or multiple episodes during a short period, each requiring medical attention
- Synonym(s): nosebleed

EPIDEMIOLOGY

Incidence
- Very common in the United States
- Estimated lifetime prevalence: ~60%
- Bimodal, with peaks in children up to 15 years and in adults >50 years, particularly ages 70 to 79 years
- Most common in males <49 years
- Rare in children age <2 years
- ~6% of patients require medical or surgical intervention; accounts for ~1 in 200 ER visits

ETIOLOGY AND PATHOPHYSIOLOGY
- Local versus systemic disease. Most nosebleeds are due to local causes.
- Anterior: 90–95% of all cases (Kiesselbach plexus)
- Posterior: 5–10% of cases (Woodruff plexus); usually branches of sphenopalatine arteries: may be asymptomatic or may present with other symptoms (hematemesis, hemoptysis)
- Idiopathic
- Local inflammation/irritation
  - Infection (viral URI, sinusitis, TB, syphilis)
  - Irritant inhalation (smoking, rhinitis)
  - Topical steroid or antihistamine use
  - Septal deviation (more air movement on one side)
  - Low humidity, nasal oxygen use, CPAP
  - Tumors: benign, malignant
  - Vascular malformations
- Trauma
  - Epistaxis digitorum (nose picking)
  - Foreign bodies
  - Septal perforation
  - Nasal fracture
  - Nasal surgery
- Systemic
  - Thromboeytopenia
  - Congenital or acquired coagulopathies
  - Liver or renal disease
– Chronic alcohol abuse
– Leukemia
– Anticoagulant drug use
– CHF
– Hereditary hemorrhagic telangiectasia (HHT)
– Collagen abnormalities
– Mitral valve stenosis
– Multiple myeloma
– Polycythemia vera
– HIV

RISK FACTORS

● Local irritation from multiple causes
● Medications/supplements including aspirin, clopidogrel, ginseng, garlic, ginkgo biloba, sildenafil, warfarin, and other anticoagulant
● Prior septoplasty/turbinate procedures, anemia, and thrombocytopenia are risk factors for recurrent epistaxis.

GENERAL PREVENTION

● Humidification at night
● Cut fingernails and minimize picking.
● For topical-nasal medication users, direct spray laterally away from septum. Use opposite hand to spray (i.e., right hand to spray in left nostril).
● Petroleum jelly to prevent anterior mucosal drying
● Control hypertension (HTN) (controversial association with increased risk for recurrent epistaxis).

COMMONLY ASSOCIATED CONDITIONS

● Vascular malformation/telangiectasia (HHT)
● Neoplasm (rare; consider if persistent and unilateral)
● Systemic
  ● Coagulopathy: primary or iatrogenic
  ● Thrombocytopenia
  ● Cirrhosis
  ● Renal failure
  ● Alcoholism
● No proven association with HTN but may make control of bleeding more difficult

DIAGNOSIS

HISTORY

● Assess airway patency and cardiovascular stability.
● Determine on which side bleeding began, anterior or posterior, duration.
● Define trauma (including nose picking) or other precipitating events.
● Previous episodes
● Comorbid conditions (cardiovascular compromise symptoms)
● Current medications including over-the-counter and supplements
Nausea, hematemesis, or hemoptysis may indicate a posterior and more severe bleed.

**PHYSICAL EXAM**
- Blood loss through one or both nostrils in most cases is due to anterior nasal septal bleeding and can often be directly visualized.
- Focus on localizing site of bleeding to anterior versus posterior nasal cavity.
- Patient is seated, head forward, to avoid blood going down the posterior pharynx.
- Use of nasal speculum improves visualization.

**DIFFERENTIAL DIAGNOSIS**
- Diagnosis usually apparent; the differential for the etiology is key.
- Posterior bleeding must be included in the differential for any chronic blood loss.

**DIAGNOSTIC TESTS & INTERPRETATION**
Lab testing is not indicated in most uncomplicated cases in which bleeding is easily controlled.

**Initial Tests (lab, imaging)**
- Mild cases, responsive to pressure: no labs
- For recurrent or intractable cases
  - CBC, PT/PTT, BMP
- PT/PTT if on warfarin or other medications affecting coagulation
- Crossmatch when appropriate
- Toxicology screen when nasal use of illicit drugs is suspected
- For most cases, imaging is not indicated.

**Follow-Up Tests & Special Considerations**
Consider neoplasm if recurrent unilateral epistaxis, especially if not responding to treatment.

**Diagnostic Procedures/Other**
Nasal endoscopy

**Pediatric Considerations**
More likely anterior, idiopathic, and recurrent

**Geriatric Considerations**
More likely to be posterior bleed

**TREATMENT**
- Most cases are managed as outpatient (1)[B].
- Home use—Nosebleed QR: a nonprescription powder of hydrophilic polymer with potassium salt; induces scab formation
- Patient applies direct pressure by pinching the lower part of the nose (nasal ala) for 5 to 20 minutes without a break. This stops bleeding in most patients.
- Cleanse nasal cavity of blood clots by blowing nose.
- An ice pack placed over the dorsum of the nose may help with hemostasis.
- Inspect the nasal septum for the bleeding site.

**GENERAL MEASURES**
Resuscitation, as indicated. Use universal “airway/breathing/circulation (ABC)” approach.

**MEDICATION**

**First Line**
If general measures fail, affected naris may be sprayed with topical vasoconstrictor, such as:
- Phenylephrine: 0.5–1%
- Oxymetazoline: 0.05%
- Epinephrine: 1:1,000
- Cocaine: 4%

**Second Line**
- Chemical (silver nitrate) or electrical cautery
- Nasal packing: ribbon gauze, nasal tampons, nasal balloon catheter
- For intractable/refractory: Consider surgical ligation, endoscopic ligation/cauterization, endovascular embolization.

**ISSUES FOR REFERRAL**
- Posterior bleeding frequently requires an otolaryngology consultation.
- Anterior bleeding that fails conservative measures, packing, and cauterization
- Recurrent episodes
- HHT patients should establish care with ENT.
- Concurrent anticoagulation
  - If bleeding stops with packing, may continue same dose of warfarin if INR therapeutic; decrease dose if supratherapeutic INR.
  - If bleeding persists despite packing, stop anticoagulation and administer vitamin K 10 mg IV ×1, recheck INR in 30 minutes, if still >1.5, give PCC.
  - Novel anticoagulation may be associated with lower rates of epistaxis than warfarin. When epistaxis occurs, it may be harder to control.

**ADDITIONAL THERAPIES**
- Nasal packing: either with ribbon gauze or preformed nasal tampons. Systemic prophylactic antibiotics are unnecessary in the majority of patients with nasal packs; topical antibiotics may be as effective and cheaper (2)[B].
- FloSeal: A biodegradable hemostatic sealant (a thrombin-type gel) in one study is more effective and better tolerated than packing (3)[B].
- Local application of tranexamic acid may reduce bleeding time as compared to anterior packing (4).
- If an actively bleeding anterior septal site is visualized, this may be treated with gentle silver nitrate cautery for ~10 seconds for definitive treatment. 75% silver nitrate is preferred. Apply in a spiral fashion, starting around the bleeding vessel, moving inward.
- Limit cautery (silver nitrate) to one side of septum, or wait 4 to 6 weeks in between treatments to reduce risk of perforation.
- Posterior: Posterior packing or tamponade with balloon devices (Foley catheter has been used). Inpatient monitoring is generally required.
- Recurrent epistaxis: Cochrane review in children shows no difference in effectiveness between antiseptic nasal cream, petroleum jelly, silver nitrate cautery, or no treatment.
  - Silver nitrate cautery followed by 4 weeks of antiseptic cream may be better than antiseptic
cream alone (5).

SURGERY/OTHER PROCEDURES

- Packing
  - Layering of Vaseline ribbon gauze (1/2 inch)
    - For gauze packing, be certain that both ends of the ribbon gauze protrude from the nostril.
    - Packing is layered from the floor upward.
    - Secure packing with gauze across the outside of the nostril.
  - Nasal tampon may be used after lubricating the tip with KY Jelly or antibiotic cream or ointment.
  - Additional saline may be needed to expand the tampon if the bleeding has slowed.
  - Merocel and Rapid Rhino packs are easier to use than gauze packing and are usually well tolerated.
- Posterior bleed
  - In the emergent setting, this may be attempted utilizing a Foley catheter or a specific posterior packing balloon.
  - With both methods, the tubing is introduced through the nose similar to the passage of a nasogastric tube. Once it reaches the posterior oral pharynx, the balloon is inflated, and the tubing is pulled back outward to tamponade the posterior bleeding source.
    - If using a Foley catheter (10 to 14F catheter), the balloon can be inflated with 10 mL of saline.
    - Traction is maintained with an umbilical cord clamp with adequate padding between the clip and the nose to avoid injury.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Consider hospitalization for elderly or for patients with posterior bleeding or coagulopathy; may also consider if significant comorbidities
- Admission criteria/initial stabilization
  - Posterior bleed
  - Hemodynamic changes
  - Clotting dysfunction
  - Universal ABC approach. Stop blood loss.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Hemodynamic monitoring if severe blood loss
- 24-Hour minimum for leaving packing in place; some recommend 3 to 5 days. Rebleed usually occurs between 24 and 48 hours. Longer durations of packing have increased risk of mucosal injury and toxic shock syndrome.

PATIENT EDUCATION

- Demonstrate proper pinching pressure techniques.
- Avoidance of trauma or irritants is key.
- Management of systemic illness and proper use of medication
PROGNOSIS
- Most are self-limited.
- Good results with proper treatment

COMPLICATIONS
- Septal perforation
- Pressure-induced tissue necrosis of the nasal mucosa
- Toxic shock syndrome with packing
- Arrhythmias triggered by packing (particularly posterior)

REFERENCES

ADDITIONAL READING

CODES
ICD10
R04.0 Epistaxis

CLINICAL PEARLS
- Most epistaxis is anterior and responds well to timed pressure over the anterior nares for 5 to 20 minutes.
- Most nosebleeds are idiopathic or as a result of nose picking.
- Posterior nosebleeds can be asymptomatic or present with nausea, hematemesis, or heme-positive stool.
- Consider evaluation for neoplasm in cases of recurrent unilateral epistaxis.
BASICS

DESCRIPTION

- Erectile dysfunction (ED): the consistent or recurrent inability to acquire or sustain an erection of sufficient rigidity and duration for sexual intercourse
- In the past, ED was assumed to be a symptom of the aging process in men, but it is more often the result of concurrent medical conditions of the patient or from medications that patients may be taking to treat those conditions.
- Sexual problems are frequent among older men and have a detrimental effect on their quality of life but are infrequently discussed with their physicians.
- Synonym(s): impotence

EPIDEMIOLOGY

Incidence

It is estimated that >600,000 new cases of ED will be diagnosed annually in the United States, although this may be an underestimation of the true incidence, as ED is vastly underreported.

Prevalence

Overall prevalence for some degree of ED:

- 52% in men age 40 to 70 years
- Age-related increase ranging from 12.4% in men age 40 to 49 years up to 46.6% in men age 50 to 69 years

ETIOLOGY AND PATHOPHYSIOLOGY

- ED is a neurovascular event.
  - With stimulation, there is release of nitrous oxide, which increases production of cyclic guanosine 3′,5′-monophosphate (cGMP).
  - This leads to relaxation of cavernous smooth muscle, leading to increased blood flow to penis.
  - As cavernosal sinusoids distend with blood, there is passive compression of subtunical veins, which decreases venous outflow, and this leads to an erection.
- Alterations in any of these events lead to ED.
- ED may result from problems with systems required for normal penile erection.
  - Vascular: diseases that compromise blood flow
    - Peripheral vascular disease, arteriosclerosis, essential hypertension
  - Neurologic: diseases that impair nerve conduction to brain or penile vasculature
    - Spinal cord injury, stroke, diabetes
  - Endocrine: diseases associated with changes in testosterone, luteinizing hormone, prolactin levels
  - Structural: phimosis, lichen sclerosis, congenital curvature
  - Psychological: patients suffering from malaise, depression, performance anxiety
- Social habits such as smoking or excessive alcohol intake
- Medications may cause ED.
Prostate cancer treatment
Structural injury or trauma (bicycling accident)

**Genetics**
Rarely related to chromosomal disorders

**RISK FACTORS**
- Advancing age
- Cardiovascular disease
- Diabetes mellitus
- Metabolic syndrome
- Sedentary lifestyle
- Cigarette smoking
- Urologic surgery, radiation, trauma/injury to pelvic area or spinal cord
- Medications that induce ED
  - SSRIs, β-blockers, clonidine, digoxin, spironolactone, antiandrogens, corticosteroids, H₂ blockers, anticonvulsants
- Central neurologic and endocrinologic conditions
- Substance abuse (alcohol, cocaine, opioids, marijuana)
- Psychological conditions: stress, anxiety, or depression; sexual abuse; relationship problems

**GENERAL PREVENTION**
The two best ways to prevent ED are by the following:
- Making healthy lifestyle choices by exercising regularly, eating well-balanced meals, limiting alcohol, and avoiding smoking
- Treating existing health problems and working with your patients to manage diabetes, heart disease, and other chronic problems

**ALERT**
Aging alone is not a cause.

**COMMONLY ASSOCIATED CONDITIONS**
- Cardiovascular disease:
  - Men with ED have a greater likelihood of having angina, myocardial infarction, stroke, transient ischemic attack, congestive heart failure, or cardiac arrhythmia compared to men without ED (1).
- Diabetes
- Neurologic conditions
- Metabolic syndrome
- Psychiatric disorders

**DIAGNOSIS**
Inability to achieve or maintain erection satisfactory for intercourse

**HISTORY**
- Identify concurrent medical illnesses or surgical procedures, history of trauma, and a list of current medications (e.g., antihypertensive meds).
• Psychosocial history: smoking, ethanol intake, recreational drug use, anxiety and depression, satisfaction with current relationship
• Presence or absence of morning erections
• Speed of onset and duration of symptoms
• Relationship of symptoms to libido
• Detailed sexual history important to rule out premature ejaculation, as this is frequently confused with ED

**PHYSICAL EXAM**
• Signs and symptoms of hypogonadism: gynecomastia, small testicles, decreased body hair
• Penile plaques (Peyronie disease)
• Detailed examination of the cardiovascular, neurologic, and genitourinary systems
  – Blood pressure, waist circumference, BMI
  – Check femoral and lower extremity pulses to assess vascular supply to genitals.
  – Check anal sphincter tone and genital reflexes, including cremasterics and bulbocavernosus.

**DIFFERENTIAL DIAGNOSIS**
• Premature ejaculation
• Decreased libido
• Anorgasmia
• Sudden versus chronic ED

**DIAGNOSTIC TESTS & INTERPRETATION**
Vascular and/or neurologic assessment and monitoring of nocturnal erections may be indicated in selected patients but not for routine workup (2)[C].

**Initial Tests (lab, imaging)**
• Hgb A1c, lipid panel, CBC, BMP, TSH, morning total and free testosterone level (1)[C]
• Doppler, angiogram, and cavernosogram are available radiologic modalities but not recommended in routine practice for the diagnosis of ED (2)[C].

**Follow-Up Tests & Special Considerations**
Other hormonal tests, such as prolactin, should only be ordered when there is suspicion for a specific endocrinopathy.

**Diagnostic Procedures/Other**
Questionnaires can be offered to assess the severity of ED, including the IIEF and its validated and more easily administered abridged version, the Sexual Health Inventory for Men (SHIM) (2) [C].

**TREATMENT**
• Lifestyle modifications and managing medications contributing to ED is first-line therapy for ED (3)[C]. Use least invasive therapy first; reserve more invasive therapies for nonresponders.
• Cardiovascular risk stratification and risk-factor management is recommended in all men with
vascular ED (4).

- Current smoking is significantly associated with ED, and smoking cessation has a beneficial effect on the restoration of erectile function (1)[A].
- Phosphodiesterase type 5 (PDE-5) inhibitors are the first-line treatment for ED (1)[A].

**GENERAL MEASURES**

- Psychosexual therapy alone or in combination with psychoactive drugs may be helpful in men whose ED is related to depression or anxiety (5).
- Weight loss and increased physical activity for obese men with ED. Men with metabolic syndrome should be counseled to make lifestyle modifications to reduce the risk of cardiovascular events and ED (1)[B].

**MEDICATION**

**First Line**

PDE-5 inhibitors are effective in the treatment of ED in many men, including those with diabetes mellitus and spinal cord injury and sexual dysfunction associated with antidepressants (6). Choice should be based on patient’s preference (cost, ease of use, and adverse effects). There is insufficient evidence to support the superiority of one agent over the others (3)[A]:

- Sildenafil (Viagra): usual daily dose: 50 to 100 mg within at least 60 minutes of sexual intercourse
- Vardenafil (Levitra): usual daily dose 5 to 20 mg within at least 60 minutes of sexual intercourse
- Vardenafil (Staxyn): ODT: usual dose 10 mg within 60 minutes of sexual intercourse
- Tadalafil (Cialis): usual daily dose 5 to 20 mg within at least 30 minutes of sexual intercourse or 2.5 mg once daily without regard to sexual activity
- Avanafil (Stendra): usual daily dose: 50 to 200 mg within at least 15 to 30 minutes of sexual intercourse

- Adverse effects of PDE-5 inhibitors: headache, facial flushing, dyspepsia, nasal congestion, dizziness, hypotension, increased sensitivity to light (sildenafil and vardenafil), vision changes, lower back pain (tadalafil), and priapism (with excessive doses)
- Sildenafil and vardenafil should be taken on an empty stomach for maximum effectiveness.

**Geriatric Considerations**

Use doses at the lower end of the dosing range for elderly patients and evaluate exercise tolerance before prescribing.

- Sildenafil 25 mg daily
- Vardenafil 5 mg daily

**Second Line**

Intraurethral and intracavernosal injectables are second-line therapies shown to be effective and should be administered based on patient preference (1)[B]. Intraurethral suppositories are a less invasive treatment option than intracavernosal injections; however, they are not as effective (3)[C]. Alprostadil, also known as prostaglandin E1, causes smooth muscle relaxation of the arterial blood vessels and sinusoidal tissues in the corpora:

- Intraurethral alprostadil (Muse):
  - Intraurethral suppository: 125-, 250-, 500-, and 1,000-μg pellets. Administer 5 to 50 minutes before intercourse. No >2 doses in 24 hours are recommended.
Intracavernosal alprostadil (available in two formulations):
  – Alprostadil (Caverject): usual dose: 10 to 20 μg, with max dose of 60 μg. Injection should be made at right angles into one of the lateral surfaces of the proximal 3rd of the penis using a 0.5-inch, 27- or 30-gauge needle. Do not use >3 times a week or more than once in 24 hours.
  – Alprostadil may also be combined with papaverine (Bimix) plus phentolamine (Trimix), plus atropine (Quadmix).

Vacuum Erection Device (VED): non-invasive option, available over the counter.

Penile Prosthesis (7)

**ALERT**

Initial trial dose of second-line agents should be administered under supervision of a specialist or primary care physician with expertise in these therapies.

Patient should notify physician if erection lasts >4 hours for immediate attention.

Do not use vacuum devices in men with sickle cell anemia or blood dyscrasias.

Testosterone supplementation in men with hypogonadism improves ED and libido (6)[B]. Available formulations include injectable depots, transdermal patches and gels, SC pellets, and oral therapy.

Best practices in urology recommendation: Do not prescribe testosterone to men with ED who have normal testosterone levels (1).

Contraindications:
  – Nitroglycerin (or other nitrates) and phosphodiesterase inhibitors: potential for severe, fatal hypotension
  – Precautions/side effects:
    o Testosterone: precautions: Exogenous testosterone reduces sperm count and thus do not use in patients wishing to keep fertility; side effects: acne, sodium retention
    o Intraurethral suppository: local penile pain, urethral bleeding, dizziness, and dysuria
    o Intracavernosal injection: penile pain, edema and hematoma, palpable nodules or plaques, and priapism
    o Sildenafil: hypotension (caution for patients on nitrates)
    o PDE-5 inhibitors: Use caution with congenital prolonged QT syndrome, class Ia or II antiarrhythmics, nitroglycerin, α-blockers (e.g., terazosin, tamsulosin), retinal disease, unstable cardiac disease, liver and renal failure.
    o Significant possible interactions
    o PDE-5 inhibitor concentration is affected by CYP3A4 inhibitors (e.g., erythromycin, indinavir, ketoconazole, ritonavir, amiodarone, cimetidine, clarithromycin, delavirdine, diltiazem, fluoxetine, fluvoxamine, grapefruit juice, itraconazole, nefazodone, nevirapine, saquinavir, and verapamil). Serum concentrations and/or toxicity may be increased. Lower starting doses should be used in these patients.
    o PDE-5 inhibitor concentration may be reduced by rifampin and phenytoin.

**ADDITIONAL THERAPIES**

Men with relationship difficulties who received therapy plus sildenafil had more successful intercourse than those who received only sildenafil (8)[A].

**SURGERY/OTHER PROCEDURES**

Penile prosthesis should be reserved for patients who have failed or are ineligible first- or
second-line therapies.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Trazodone, yohimbine, and herbal therapies are not recommended for the treatment of ED, as they have not proven to be efficacious. Low intensity shock wave treatment is not FDA approved, but some studies have shown improvement particularly in younger, non-diabetic patients with milder cases of ED. Further research is needed (9).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Treatment should be assessed at baseline and after the patient has completed at least 1 to 3 weeks of a specific treatment: Monitor the quality and quantity of penile erections and monitor the level of satisfaction patient achieves.

**DIET**

Diet and exercise recommended to achieve a normal body mass index; limit alcohol.

**PROGNOSIS**

- All commercially available PDE-5 inhibitors are equally effective. In the presence of sexual stimulation, they are 55–80% effective.
  - Lower success rates with diabetes mellitus and radical prostatectomy patients who suffer from ED
- Overall effectiveness is 70–90% for intracavernosal alprostadil and 43–60% for intraurethral alprostadil (2)[B].
- Penile prostheses are associated with an 85–90% patient satisfaction rate (2)[C].

**REFERENCES**

8. Melnik T, Soares BG, Nasselo AG. Psychosocial interventions for erectile dysfunction.

**CODES**

**ICD10**
- N52.9 Male erectile dysfunction, unspecified
- N52.1 Erectile dysfunction due to diseases classified elsewhere
- F52.21 Male erectile disorder

**CLINICAL PEARLS**

- Nitrates should be withheld for 24 hours after sildenafil or vardenafil administration and for 48 hours after use of tadalafil. PDE-5 inhibitors are contraindicated in patients taking concurrent nitrates of any form (regular or intermittent nitrate therapy), as it can lead to severe hypotension and syncope.
- Reserve surgical treatment for patients who do not respond to drug treatment.
- The use of PDE-5 inhibitors with α-adrenergic antagonists may increase the risk of hypotension. Tamsulosin is the least likely to cause orthostatic hypotension.
- Avanafil should not be used with strong CYP3A4 inhibitors and max dose should be 50 mg with moderate CYP3A4 inhibitors.
- ED may be a marker for subclinical cardiovascular disease. Thoroughly assess patients with nonpsychogenic ED for CV risks.
BASICS

DESCRIPTION
- Distinct form of cellulitis: notable for acute, well-demarcated, superficial bacterial skin infection with lymphatic involvement almost always caused by Streptococcus pyogenes
- Usually acute, but a chronic recurrent form can also exist (1)
- Nonpurulent
- System(s) affected: skin, exocrine

EPIEDEMOLOGY
- Predominant age: infants, children, and adults >45 years
- Greatest in elderly (>75 years)
- No gender/racial predilection

Incidence
- Erysipelas occurs in ~1/1,000 persons/year.
- Incidence on the rise since the 1980s (2)

Prevalence
Unknown

ETIOLOGY AND PATHOPHYSIOLOGY
- Group A streptococci induce inflammation and activation of the contact system, a proinflammatory pathway with antithrombotic activity, releasing proteinases and proinflammatory cytokines.
- The generation of antibacterial peptides and the release of bradykinin, a proinflammatory peptide, increase vascular permeability and induce fever and pain.
- The M proteins from the group A streptococcal cell wall interact with neutrophils, leading to the secretion of heparin-binding protein, an inflammatory mediator that also induces vascular leakage.
- This cascade of reactions leads to the symptoms seen in erysipelas: fever, pain, erythema, and edema.
- Group A β-hemolytic streptococci primarily; commonly S. pyogenes, occasionally, other Streptococcus groups C/G
- Rarely, group B streptococci/Staphylococcus aureus may be involved.

RISK FACTORS
- Disruption in the skin barrier (surgical incisions, insect bites, eczematous lesions, local trauma, abrasions, dermatophytic infections, intravenous drug user [IVDU])
- Chronic diseases (diabetes, malnutrition, nephrotic syndrome, heart failure)
- Immunocompromised (HIV)/debilitated
- Fissured skin (especially at the nose and ears)
- Toe-web intertrigo and lymphedema
- Leg ulcers/stasis dermatitis
- Venous/lymphatic insufficiency (saphenectomy, varicose veins of leg, phlebitis, radiotherapy, mastectomy, lymphadenectomy)
- Alcohol abuse
- Morbid obesity
- Recent streptococcal pharyngitis
- Varicella

**GENERAL PREVENTION**
- Good skin hygiene
- It is recommended that predisposing medical conditions, such as tinea pedis and stasis dermatitis, be appropriately managed first.
- Men who shave within 5 days of facial erysipelas are more likely to have a recurrence.
- With recurrences, search for other possible sources of streptococcal infection (e.g., tonsils, sinuses).
- Compression stockings should be encouraged for patients with lower extremity edema.
- Consider suppressive prophylactic antibiotic therapy, such as penicillin, in patients with >2 episodes in a 12-month period.

**Pediatric Considerations**
Group B Streptococcus may be a cause of erysipelas in neonates/infants.

**DIAGNOSIS**
Prodromal symptoms before the skin eruption of erysipelas may include:
- Moderate- to high-grade fever
- Chills
- Headache
- Malaise
- Anorexia, usually in the first 48 hours
- Vomiting
- Arthralgias

**ALERT**
It is important to differentiate erysipelas from a methicillin-resistant S. aureus (MRSA) infection, which usually presents with an indurated center, significant pain, and later evidence of abscess formation.

**PHYSICAL EXAM**
- Vital signs: moderate- to high-grade fever with resultant tachycardia. Hypotension may occur.
- The presence of a fever in erysipelas can be considered a differentiating factor from other skin infections.
- Headache and vomiting may be prominent.
- Acute onset of intense erythema; well-demarcated painful plaque (3)
- Peau d’orange appearance
- Milian ear sign (Erythema involves skin of ear as well as face implies erysipelas.)
Vesicles and bullae may form but are not uniformly present.
Desquamation may occur later.
Lymphangitis
Location (most commonly unilateral; bilateral presentation should prompt consideration of alternative diagnosis)
  – Lower extremity 70–80% of cases
  – Face involvement is less common (5–20%), especially nose and ears.
  – Chronic form usually recurs at site of the previous infection and may recur years after initial episode.
Patients on systemic steroids may be more difficult to diagnose because signs and symptoms of the infection may be masked by anti-inflammatory action of the steroids.
Systemic toxicity resolves rapidly with treatment; skin lesions desquamate on days 5 to 10 but usually heal without scarring.
In geriatric patients, facial involvement presents in a butterfly pattern. Pustules characteristically absent and regional lymphadenopathy with lymphangitic streaking is seen.

**Pediatric Considerations**
Abdominal involvement is more common in infants, especially around umbilical stump.
Face, scalp, and leg involvement are common in older children due to the excoriations when scratching in atopic dermatitis, allowing an easy port of entry.

**Geriatric Considerations**
Fever may not be as prominent.
80% of cases affect the lower extremities. The rest are usually on the face.
High-output cardiac failure may occur in debilitated patients with underlying cardiac disease.
More susceptible to complications

**DIFFERENTIAL DIAGNOSIS**
Cellulitis (Margins are less clear and do not involve ear.)
Necrotizing fasciitis (systemic illness and more pain)
Skin abscess (feel for area of fluctuance)
DVT (needs to rule out if clinically suspected)
Acute gout (Check patient history.)
Insect bite (Check patient history.)
Dermatophytes
Impetigo (blistered/crusted appearance; superficial)
Ecthyma (ulcerative impetigo)
Herpes zoster (dermatomal distribution)
Erythema annulare centrifugum (raised pink-red ring/bull’s-eye marks)
Contact dermatitis (no fever, pruritic, not painful)
Giant cell urticaria (transient, wheal appearance, severe itching)
Angioneurotic edema (no fever)
Scarlet fever (widespread rash with indistinct borders and without edema; rash is most common early in skin folds; develops generalized “sandpaper” feeling as it progresses)
Toxic shock syndrome (diffuse erythema with evidence of multiorgan involvement)
Lupus (of the face; less fever, positive antinuclear antibodies)
Polychondritis (common site is the ear)
Other bacterial infections to consider:
- Meat, shellfish, fish, and poultry workers: Erysipelothrix rhusiopathiae (known as erysipeloid)
- Human bite: Eikenella corrodens
- Cat/dog bite: Pasteurella multocida/Capnocytophaga canimorsus
- Salt water exposure: Vibrio vulnificus
- Fresh/brackish water exposure: Aeromonas hydrophila

**DIAGNOSTIC TESTS & INTERPRETATION**
Reserve diagnostic tests for severely ill, toxic patients, patients who failed initial antibiotic therapy, or those who are immunosuppressed.

**Initial Tests (lab, imaging)**
- Leukocytosis
- Blood culture (<5% positive)
- Elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)
- Streptococci may be cultured from exudate/noninvolved sites.

**Test Interpretation**
Biopsy is not needed; however, skin findings would show
- Dermal and epidermal edema, extending into the SC tissues
- Peau d’orange appearance caused by edema in the superficial tissue surrounding the hair follicles
- Vasodilation and enlarged lymphatics
- Mixed interstitial infiltrate mainly consisting of neutrophils and mononuclear cells
- Endothelial cell swelling
- Gram-positive cocci in lymphatics and tissue with rare invasion of local blood vessels
- Fibrotic thickening of lymphatic vessel walls with possible luminal occlusion may be seen in recurrent erysipelas.

**TREATMENT**

**GENERAL MEASURES**
- Symptomatic treatment of myalgias and fever
- Adequate fluid intake
- Local treatment with cold compresses
- Elevation of affected extremity
- Appropriate therapy for any underlying predisposing condition

**MEDICATION**
- Antibiotics cure 50–100% of infections, but which regimen is most successful is unclear.
- Antibiotics may be as effective when given orally versus intravenously.
- A 5-day course of antibiotics may be as effective as a 10-day course at curing (4)[A].

**First Line**
- Adults
  - Extremities, nondiabetic
Primary Penicillin G: 1 to 2 million U IV q6h or cefazolin 1 g IV q8h
Alternative (if penicillin allergic)
- Vancomycin 15 mg/kg IV q12h
- When afebrile, penicillin VK 500 mg PO QID AC and HS
- Total 10 days, diabetics
  - Early mild:
    - Trimethoprim-sulfamethoxazole (TMP-SMX)-DS: 1 to 2 tabs PO BID and penicillin VK 500 mg PO QID or cephalexin 500 mg PO QID
- Severe disease
  - MP or MER or ERTA IV and linezolid 600 mg IV/PO BID or vancomycin IV or daptomycin 4 mg/kg IV q24h
- Facial
  - Primary
    - Vancomycin: 15 mg/kg (actual weight) IV q8–12h with target trough 15 to 20
  - Alternative
    - Daptomycin 4 mg/kg IV q24h or linezolid 600 mg IV q12h

Children
- Penicillin G
  - 0 to 7 days, <2,000 g = 50,000 U/kg q12h
  - 8 to 28 days, <2,000 g = 75,000 U/kg q8h
  - 0 to 7 days, >2,000 g = 50,000 U/kg q8h
  - 8 to 28 days, >2,000 g = 50,000 U/kg q6h
  - >28 days = 50,000 U/kg/day
- Cefazolin
  - 0 to 7 days, <2,000 g = 25 mg/kg q12h
  - 8 to 28 days, <2,000 g = 25 mg/kg q12h
  - 0 to 7 days, >2,000 g = 25 mg/kg q12h
  - 8 to 28 days, >2,000 g = 25 mg/kg q8h
  - >28 days = 25 mg/kg q8h

No reported group A streptococci resistance to β-lactam antibiotics
In chronic recurrent infections, prophylactic treatment after the acute infection resolves:
- Penicillin G benzathine: 1.2 million U IM q4wk or penicillin VK 500 mg PO BID or azithromycin 250 mg PO QD
If staphylococcal infection is suspected or if patient is acutely ill, consider a β–lactamase-stable antibiotic.
Consider community-acquired MRSA, and depending on regional sensitivity, may treat MRSA with TMP-SMX DS 1 tab PO BID or vancomycin 1 g IV q12h or doxycycline 100 mg PO BID.

ISSUES FOR REFERRAL
Recurrent infection, treatment failure

ADDITIONAL THERAPIES
Some patients may notice a deepening of erythema after initiating antimicrobial therapy. This may be due to the destruction of pathogens that release enzymes, increasing local inflammation. In this case, treatment with corticosteroids, in addition to antimicrobials, can mildly reduce
healing time and antibiotic duration in patients with erysipelas. Consider prednisolone 30 mg/day with taper over 8 days.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission criteria/initial stabilization
  - Patient with systemic toxicity
  - Patient with high-risk factors (e.g., elderly, lymphedema, post-splenectomy, diabetes)
  - Failed outpatient care
- IV therapy if systemic toxicity/unable to tolerate PO
- Discharge criteria: no evidence of systemic toxicity with resolution of erythema and swelling

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Bed rest with elevation of extremity during acute infection and then activity as tolerated

**Patient Monitoring**
Patients should be treated until all symptoms and skin manifestations have resolved.

**PATIENT EDUCATION**
Stress importance of completing prescribed medication regimen.

**PROGNOSIS**
- Patients should recover fully if adequately treated.
- May experience deepening of erythema after initiation of antibiotics
- Most respond to therapy after 24 to 48 hours.
- Mortality is <1% in patients receiving appropriate treatment.
- Bullae formation suggests longer disease course and often indicates a concomitant S. aureus infection that may require antibiotic coverage for MRSA.
- Chronic edema/scarring may result from chronic recurrent cases.
- Rarely, obstructive lymphadenitis may result from chronic recurrent cases.

**COMPLICATIONS**
- Recurrent infection
- Abscess (suggests staphylococcal infection)
- Necrotizing fasciitis
- Lymphedema (most prominent risk factor for recurrence) (5)
- Bacteremia, which may lead to sepsis
- Pneumonia (due to sepsis/toxin-producing organism)
- Meningitis (due to sepsis/toxin-producing organism)
- Embolism
- Gangrene
- Bursitis, septic arthritis, tendinitis, or osteitis

**REFERENCES**

ADDITIONAL READING

CODES

ICD10
A46 Erysipelas

CLINICAL PEARLS

- Athlete’s foot is the most common portal of entry.
- Erysipelas is distinguished from cellulitis by its sharp, shiny, fiery-red, raised border.
- In recurrent cases, search for other possible source of streptococcal infection (e.g., tonsils, sinuses, intertrigo).
- Most erysipelas infections now occur on the legs, rather than the face.
ERYTHEMA MULTIFORME
Losika Sivaganeshan, MD, MPH • Pradeepa P. Vimalachandran, MD, MPH

BASICS

- Erythema multiforme (EM) is relatively common, acute, recurrent, self-limiting inflammatory disease.
  - Mostly (~90% of cases) triggered by infectious agents (up to 50% by herpes simplex virus [HSV]-1 or -2), or less commonly, by drugs and vaccinations (1,2).
  - Skin lesions include acrally distributed, distinct targetoid lesions with concentric color variation, sometimes accompanied by oral, genital, or ocular mucosal lesions (1,3).
  - Flat, atypical lesions and macules with or without blisters are more suggestive of Stevens-Johnson syndrome (SJS) or toxic epidermal necrolysis (TEN) (4,5).
- There are no universal diagnostic criteria, but clinical history, clinical examination, skin biopsy, laboratory studies, and special consideration of persistent EM are all included in making a diagnosis.

DESCRIPTION

- Two subtypes, erythema multiforme minor (EMm) and erythema multiforme major (EMM), with the former involving none or one mucous membrane and the latter involving at least two mucous membrane sites. EMM is now separate from SJS and TEN.
- Recurrent EM is defined as >3 attacks but has a mean number of 6 attacks (range 2 to 24) per year and a mean duration of 6 to 9.5 years (range 2 to 36) (1).

EPIDEMIOLOGY

Incidence
Annual U.S. incidence is estimated at <1% (1).

Prevalence
- Peak incidence in 20s to 40s; rare <3 years and >50 years of age
- Slight male predominance is observed.

ETIOLOGY AND PATHOPHYSIOLOGY

- The exact pathophysiology of EM is incompletely understood but appears to be the result of a TH1-mediated immune response to an inciting event such as infection or drug exposure.
- Genetic susceptibility can be a predisposing factor in some patients with EM. Different HLA alleles have been found to be consistent in patients with EM.
- HSV containing a certain HSV pol, a polymerase associated with the HSV-triggered EM seems to involve autoimmunity activation and a cell-mediated response (1).
- With electron microscopy, there is evidence of lichenoid inflammatory infiltrate and epidermal necrosis including circulating immune complexes, deposition of C3, IgM, and fibrin around the upper dermal blood vessels.
- SJS and TEN have an increased granulysin and perforin expression within T cells than in EM (4,5).
- Previous viral infections, particularly; also Epstein-Barr, coxsackievirus, echovirus, varicella,
mumps, poliovirus, hepatitis C, cytomegalovirus, HIV, molluscum contagiosum virus (1)
- Bacterial infections, particularly Mycoplasma pneumoniae; other reported bacterial infections include Treponema pallidum, Mycobacterium tuberculosis, and Gardnerella vaginalis (1).
- Medications, including NSAIDs, antibiotics, penicillin, sulfonamides, and antiepileptics (1,3)
- Vaccines: stronger association with HPV, MMR, and small pox vaccines, but also associated with hepatitis B, meningococcal, pneumococcal, varicella, influenza, diphtheria-pertussis-tetanus, and Haemophilus influenzae (2)
- Occupational exposures: herbicides (alachlor and butachlor), iodoacetonitrile
- Radiation therapy
- Premenstrual hormone changes (3)
- Malignancy (3)

**Genetics**
Strong association with HLA-DQB10301, particularly in herpes-related cases (1); possible association in recurrent cases with HLA-B35, -B62, -DR53

**RISK FACTORS**
Previous history of EM

**GENERAL PREVENTION**
- Known or suspected etiologic agents should be avoided.
- Acyclovir or valacyclovir may help prevent herpes-related recurrent EM.

**COMMONLY ASSOCIATED CONDITIONS**
See “Etiology and Pathophysiology” earlier.

**DIAGNOSIS**

**Clinical**

**HISTORY**
- Absent or mild prodromal symptoms
- Acute, self-limiting episodic course
- History of new medication
- Preceding HSV infection 10 to 15 days before the skin eruptions
- Rash involving the skin and sometimes the mucous membrane, most commonly the mouth
- Symptoms of any of the infections associated with EM, most commonly HSV and M. pneumoniae

**PHYSICAL EXAM**
- Acral extremities
- Symmetric cutaneous eruptions composed of targetoid lesions with concentric color variation
- Mucosal involvement
  - Oral involvement manifests as erythema, erosions, bullae, and ulcerations on both nonkeratinized and keratinized mucosal surfaces and on the vermillion of the lips; minimal involvement in EMM, if present, most commonly involves the mouth.
  - Can include any mucosal tissue including genital, ocular, oral, and so forth
  - At least two mucosal sites involved in EMM, including eyes (conjunctivitis, keratitis);
mouth (stomatitis, cheilitis, characteristic blood-stained crusted erosions on lips); and probable trachea, bronchi, GI tract, or genital tract (balanitis and vulvitis) (5)

DIFFERENTIAL DIAGNOSIS

- SJS
  - Generalized distribution of lesions; concentrated on the trunk
  - Macular atypical targetoid lesions
  - Flat target lesions or macules with coalescence of lesions
  - Blisters and skin detachment <10% of the total body surface area (5)
  - 1–5% mortality
  - Presence of constitutional symptoms with presence of high fever (>38.5°C) more likely with SJS than EM
  - More likely to have mucosal involvement at ≥2 sites, lymphadenopathy, high C-reactive protein levels (>10 mg/dL), and hepatic dysfunction and >90% have severe mucosal involvement at least at one site (1)

- TEN
  - Similar to SJS but has full-thickness skin necrosis and skin detachment >30% of the total body surface area (5,6)
  - 34–40% mortality rate

- Urticaria
- Fixed drug eruption
- Bullous pemphigoid
- Paraneoplastic pemphigoid
- Sweet syndrome
- Rowell syndrome
- Polymorphous light eruption
- Cutaneous small-vessel vasculitis
- Mucocutaneous lymph node syndrome
- Erythema annulare centrifugum
- Acute hemorrhagic edema of infancy
- Subacute cutaneous lupus erythematosus
- Contact dermatitis
- Pityriasis rosea
- HSV
- Secondary syphilis
- Tinea corporis
- Dermatitis herpetiformis
- Herpes gestationis
- Septicemia
- Serum sickness
- Viral exanthem
- Rocky Mountain spotted fever
- Meningococcemia
- Lichen planus
- Behçet syndrome
- Recurrent aphthous ulcers
- Herpetic gingivostomatitis
Granuloma annulare

**DIAGNOSTIC TESTS & INTERPRETATION**
- No lab test is indicated to make the diagnosis of EM (1).
- Skin biopsy of lesional and perilesional tissue in equivocal conditions
- Direct and indirect immunofluorescence (DIF and IIF) to differentiate EM from other vesiculobullous diseases. DIF is detected on a biopsy of perilesional skin, and IIF is detected from a blood sample (1).
- HSV tests in recurrent EM (serologic tests, swab culture, or tests using skin biopsy sample to check HSV antigens or DNA in keratinocytes by DIF or direct fluorescent antibody [DFA] or polymerase chain reaction [PCR])
- Antibody staining to IFN-γ and TNF-α to differentiate HSV from drug-associated EM
- As the second most common cause of EM, M. pneumoniae should be worked up with chest x-ray, swabs, and serologic test.
- In persistent EM, check complement levels (1).

**Initial Tests (lab, imaging)**
No imaging studies are indicated in most cases unless there is suspicion for M. pneumoniae.

**Follow-Up Tests & Special Considerations**
Chest x-ray may be necessary if an underlying pulmonary infection (M. pneumoniae) is suspected.

**Test Interpretation**
- Vacuolar interface dermatitis with CD4+ T lymphocytes and histiocytes in papillary dermis and the dermal–epidermal junction
- Superficial perivascular lymphocytic inflammation
- Satellite cell necrosis
- Necrotic keratinocytes mainly in the basal layer
- Papillary dermal edema

**TREATMENT**

**GENERAL MEASURES**
- Step 1: Discontinue or treat inciting factor (1).
- Wound care for severe cases with epidermal detachment
- Oral lesions should be addressed to insure maintenance of PO intake. This can include oral anesthetic solutions and antiseptic rinses.

**MEDICATION**
- Acute EM
  - Discontinuation of inciting factors and treatment of underlying disease (1)[B]
  - Symptomatic treatment with oral antihistamines and topical (1)[B]
  - HSV-induced EM: Most recent sources report no proven effect on the course of EM using antivirals with acute mild EM (1)[B].
  - M. pneumoniae–associated EM may require antibiotics.
- Mucosal membrane EM
- Consider high-potency topical corticosteroid gel, oral antiseptic, and oral anesthetic solutions if mild.
- If more severe, consider prednisone 40 to 60 mg/day with dosage tapered over 2 to 4 weeks (1)[B].
- Ophthalmology consultation is imperative for ocular involvement.

**Recurrent EM**
- First-line treatment with HSV-associated and idiopathic recurrent EM is antiviral prophylaxis; 12 to 24 months of prophylaxis is most effective (1)[B].
- Therapy includes acyclovir 400 mg BID, valacyclovir 500 mg BID, famciclovir 250 mg BID (1)[B].
- Second-line therapy includes dapsone (100 to 150 mg/day), azathioprine (Imuran, 100 to 150 mg/day), thalidomide (100 to 200 mg/day), tacrolimus (0.1% ointment daily), mycophenolate mofetil (CellCept, 1,000 to 1,500 mg BID), hydroxychloroquine (400 mg/day) (1)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Care at home
- Hospitalization needed for fluid and electrolyte management in patient with severe mucous membrane involvement, impaired oral intake, and dehydration
- IV antibiotics if secondary infection develops

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- The disease is self-limiting.
- Complications are rare, with no mortality.

**DIET**
As tolerated, with increased fluid intake

**PATIENT EDUCATION**
- The disease is self-limiting. However, the recurrence risk may be 30%.
- Avoid any identified etiologic agents.

**PROGNOSIS**
- Rash evolves over 1 to 2 weeks and subsequently resolves within 2 to 6 weeks, generally without scarring or sequelae.
- Following resolution, there may be some postinflammatory hyper- or hypopigmentation.

**COMPLICATIONS**
Secondary infection

CODES

ICD10

- L51.9 Erythema multiforme, unspecified
- L51.8 Other erythema multiforme
- L51.0 Nonbullous erythema multiforme

CLINICAL PEARLS

- EM is diagnosed clinically by careful review of the history, thorough detailed physical exam, and by excluding other similar disorders. No lab tests are required for the diagnosis.
- Typical lesions are characteristic targetoid or “iris” lesions but can include raised targetoids.
- Lesions are symmetrically distributed on palms, soles, dorsum of the hands, and extensor surfaces of extremities and face. The oral mucosa is the most affected mucosal region in EM.
- Management of EM involves determining the etiology when possible. The first step is to treat the suspected infection or discontinue the causative drug.
- Complications are rare. Most cases are self-limited. However, the recurrence risk may be as high as 30%.
- Recurrent cases often are secondary to HSV infection. Antiviral therapy may be beneficial.
ERYTHEMA NODOSUM
Lolwa Al-Obaid, MD • Faruq Pradhan, MD • Fredric D. Gordon, MD

BASICS

DESCRIPTION
- A delayed-type hypersensitivity reaction to various antigens, or an autoimmune reaction presenting as a panniculitis that affects subcutaneous fat
- Clinical pattern of multiple, bilateral, erythematous, tender nodules in a typically pretibial distribution that undergo a characteristic pattern of color changes, similar to that seen in bruises. Unlike erythema induratum, the lesions of erythema nodosum (EN) do not typically ulcerate.
- Occurs most commonly on the shins; less commonly on the thighs, forearms, trunk, head, or neck
- Often associated with nonspecific prodrome including fever, weight loss, and arthralgia
- Often idiopathic but may be associated with a number of clinical entities
- Usually remits spontaneously in weeks to months without scarring, atrophy, or ulceration
- Uncommon to have recurrences after initial presentation

Pregnancy Considerations
May have repeat outbreaks during pregnancy

Pediatric Considerations
Rare pediatric variant has lesions only on palms or soles, often unilateral; typically has a shorter duration in children than adults

EPIDEMIOLOGY

Incidence
- 1 to 5/100,000/year
- Predominant age: 20 to 30 years
- Predominant sex: female > male (6:1) in adults

Prevalence
- Varies geographically depending on the prevalence of disorders associated with EN
- Reported 1 to 5/100,000

ETIOLOGY AND PATHOPHYSIOLOGY
- Idiopathic: up to 55%
- Infectious: 44%. Streptococcal pharyngitis (most common), mycobacteria, mycoplasma, chlamydia, mycoplasma, coccidioidomycosis, rarely can be caused by Campylobacter spp., rickettsiae, Salmonella spp., psittacosis, syphilis
- Sarcoidosis: 11–25%
- Drugs: 3–10%; sulfonamides amoxicillin, oral contraceptives, bromides, azathioprine, vemurafenib
- Pregnancy: 2–5%
- Enteropathies: 1–4%; ulcerative colitis, Crohn disease, Behçet disease, celiac disease,
diverticulitis

- Rare causes: <1% (2)
  - Fungal: dermatophytes, coccidioidomycosis, histoplasmosis, blastomycosis
  - Viral/chlamydial: infectious mononucleosis, lymphogranuloma venereum, paravaccinia, HIV, hepatitis B, C
  - Malignancies: lymphoma/leukemia, sarcoma, myelodysplastic syndrome
  - Sweet syndrome

RISK FACTORS
See “Etiology and Pathophysiology.”

COMMONLY ASSOCIATED CONDITIONS
See “Etiology and Pathophysiology.”

DIAGNOSIS

HISTORY
- Often a prodrome 1 to 3 weeks prior to onset of lesions; can consist of malaise, fever, weight loss, cough, and arthralgia
- Increasingly tender nodules on the legs, usually over the shins
- Fever, malaise, chills, fatigue
- Headache
- Can precede systemic process by weeks

PHYSICAL EXAM
- Lesions initially present as warm, tender, erythematous firm nodules and become fluctuant, gradually fading to resemble a bruise over 1 to 2 months (erythema contusiformis).
- Typically pretibial, although can extend proximally to involve thighs or trunk (atypically can involve extensor surface of forearms)
- Diameter varies from 1 to 10 cm with poor demarcation.

DIFFERENTIAL DIAGNOSIS
- Nodular vasculitis or erythema induratum (warm ulcerating calf nodules)
- Superficial thrombophlebitis
- Cellulitis
- Weber-Christian disease (violaceous, scarring nodules)
- Lupus panniculitis
- Cutaneous polyarteritis nodosa
- Sarcoidal granulomas
- Cutaneous T-cell lymphoma
- EN leprosum (clinically similar to EN but shows vasculitis on histopathology)
- Subcutaneous infection (including Staphylococcus, Sporothrix schenckii, Nocardia brasiliensis, Mycobacterium marinum, Leishmania braziliensis)

DIAGNOSTIC TESTS & INTERPRETATION
Diagnosis is made clinically, with support of testing.
- ESR or C-reactive protein (CRP): often elevated, but can be normal in up to 40% (3)[C]
- CBC: mild leukocytosis (3)
- Urine pregnancy test (3)
- Throat culture, antistreptolysin O titer (3)
- Blood and/or stool culture, stool ova and parasites (O&P)
- Tuberculin skin testing (3)
- Seronegative rheumatoid factor

**Initial Tests (lab, imaging)**
CXR for hilar adenopathy or infiltrates related to sarcoidosis or tuberculosis (3)[C]

**Diagnostic Procedures/Other**
Deep-incisional or excisional skin biopsy including subcutaneous tissue; rarely necessary except in atypical cases with ulceration, duration >12 weeks, or absence of nodules overlying lower limbs (4)[C]

**Test Interpretation**
- Septal panniculitis without vasculitis
- Neutrophilic infiltrate in septa of fat tissue early in course
- Actinic radial (Miescher) granulomas, consisting of collections of histiocytes around a central stellate cleft, may be seen.
- Fibrosis, paraseptal granulation tissue, lymphocytes, and multinucleated giant cells predominate late in course (5).

**TREATMENT**
- Condition usually self-limited within 1 to 2 months
- All medications listed as treatment for EN are off-label uses of the medications. There are no specific FDA-approved medications.

**GENERAL MEASURES**
- Mild compression bandages and leg elevation may reduce pain (wet dressings, hot soaks, and topical medications are not useful).
- Discontinue potentially causative drugs.
- If specific cause is identified, treatment of the condition typically leads to resolution of EN.
- Indication for treatment is poorly defined in literature; hence, therapy specifically for EN is directed toward symptom management.

**MEDICATION**
**First Line**
- NSAIDs:
  - Ibuprofen 400 mg PO q4–6h (not to exceed 3,200 mg/day)
  - Indomethacin 25 to 50 mg PO TID
  - Naproxen 250 to 500 mg PO BID
- Precautions
  - GI upset/bleeding (avoid in Crohn or ulcerative colitis)
  - Fluid retention
  - Renal insufficiency
– Dose reduction in elderly, especially those with renal disease, diabetes, or heart failure
– May mask fever
– NSAIDs can increase cardiovascular (CV) risk.

**Significant possible interactions**
– May blunt antihypertensive effects of diuretics and β-blockers
– NSAIDs can elevate plasma lithium levels.
– NSAIDs can cause significant elevation and prolongation of methotrexate levels.

**Second Line**

- Potassium iodide 400 to 900 mg/day divided BID or TID for 3 to 4 weeks (for persistent lesions); need to monitor for hyperthyroidism with prolonged use; pregnancy class D (6)[B]
- Corticosteroids for severe, refractory, or recurrent cases in which an infectious workup is negative. Prednisone 1 mg/kg/day for 1 to 2 weeks is the recommended dose/duration. Potential side effects include hyperglycemia, hypertension, weight gain, worsening gastroesophageal reflux disease, mood changes, bone loss, osteonecrosis, and proximal myopathy (2).
- For EN related to Behçet disease, one can also consider colchicine 0.6 to 1.2 mg BID. Potential side effects include GI upset and diarrhea (7)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Occasionally, admission may be needed for the antecedent illness (e.g., tuberculosis).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Keep legs elevated.
- Elastic wraps or support stockings may be helpful when patients are ambulating.

**Patient Monitoring**
Monthly follow-up or as dictated by underlying disorder

**DIET**
No restrictions

**PATIENT EDUCATION**
- Lesions will resolve over a few weeks to months.
- Scarring is unlikely.
- Joint aches and pains may persist.
- <20% recur.

**PROGNOSIS**
- Individual lesions resolve generally within 2 weeks.
- Total time course of 6 to 12 weeks but may vary with underlying disease
- Joint aches and pains may persist for years.
- Lesions do not scar.
- Recurrences: occurs over variable periods, averaging several years; seen most often in sarcoid, streptococcal infection, pregnancy, and oral contraceptive use. If medication induced, avoid
recurrent exposure.

COMPLICATIONS
- Vary according to underlying disease
- None expected from lesions of EN

REFERENCES

ADDITIONAL READING

CODES
- ICD10
  - L52 Erythema nodosum
  - A18.4 Tuberculosis of skin and subcutaneous tissue

CLINICAL PEARLS
- Lesions of EN appear to be erythematous patches, but when palpated, their underlying nodularity is appreciated.
- Evaluation for a concerning underlying etiology is necessary in EN, but most cases are
idiopathic.

- EN in the setting of hilar adenopathy may be seen with multiple etiologies and does not exclusively indicate sarcoidosis.
- In patients with a history of Hodgkin lymphoma, EN may be an early sign of recurrence.
ESOPHAGEAL VARICES
Maximos Attia, MD, FAAFP • Marcelle Meseeha, MD

BASICS

DESCRIPTION
- Dilated submucosal esophageal veins connecting the portal and systemic circulations
- Most commonly results from portal hypertension (typically a result of cirrhosis)
- Variceal rupture: most common fatal complication of cirrhosis; severity of liver disease correlates with presence of varices and risk of bleeding.

EPIDEMIOLOGY

Incidence
- 30% of cirrhotic patients have varices at the time of diagnosis. This increases to 90% at 10 years.
- 1-year rate of first variceal bleeding is 5% for small varices, 15% for large varices.

Pediatric Considerations
Portal hypertension is common in chronic liver disease (CLD) in children. No clear guidelines for screening; pharmacologic or endoscopic treatment is equivalent.

Prevalence
- 50% of patients with esophageal varices experience bleeding at some point.
- Variceal bleeding: 10–20% mortality in the 6 weeks following the episode
- Gender: male > female

ETIOLOGY AND PATHOPHYSIOLOGY
- Portal hypertension causes the formation of portacaval anastomoses to decompress the portal circulation. This leads to a congested submucosal venous plexus with tortuous dilated veins, particularly in the distal esophagus. Variceal rupture results in hemorrhage.

Pathophysiology of portal hypertension:
- Increased resistance to portal flow at the level of hepatic sinusoids caused by
  - Intrahepatic vasoconstriction due to decreased nitric oxide production and increased release of endothelin-1 (ET-1), angiotensinogen, and eicosanoids
  - Sinusoidal remodeling causes disruption of blood flow.
- Increased portal flow caused by hyperdynamic circulation due to splanchnic arterial vasodilation through mediators such as nitric oxide, prostacyclin, and TNF

Causes of portal hypertension:
- Prehepatic:
  - Extrahepatic portal vein obstruction (EHPVO)
  - Massive splenomegaly with increased splenic vein blood flow
- Posthepatic:
  - Severe right-sided heart failure, constrictive pericarditis, and hepatic vein obstruction (Budd-Chiari syndrome)
- Intrahepatic:
  - Cirrhosis (accounts for most cases of portal hypertension)
– Less frequent causes are schistosomiasis, massive fatty change, diseases affecting portal microcirculation as nodular regenerative hyperplasia, and diffuse fibrosing granulomatous disease as sarcoidosis.

Genetics
Cirrhosis is rarely hereditary.

RISK FACTORS
● Cirrhosis
● In cirrhotic patients, thrombocytopenia and splenomegaly are independent predictors of esophageal varices.
● Noncirrhotic portal hypertension
● Increased bleeding risk for known varices is associated with varix size, endoscopic signs (red wale marks, cherry-red spots), vessel wall thickness, and abrupt increase in variceal pressure (i.e., Valsalva maneuver).
● MELD/Child-Pugh score; presence of portal vein thrombosis; high hepatic venous pressure gradient (HVPG)

GENERAL PREVENTION
Prevent underlying causes: Prevent alcohol abuse, administer hepatitis B vaccine, needle hygiene, IV drug use (needle exchange programs reduce risk of hepatitis; specific screening and therapy for hepatitis B and C, hemochromatosis

COMMONLY ASSOCIATED CONDITIONS
● Portal hypertensive gastropathy; varices in stomach, duodenum, colon, rectum (causes massive bleeding, unlike hemorrhoids); rarely at umbilicus (caput medusae) or ostomy sites
● Isolated gastric varices can occur due to splenic vein thrombosis/stenosis from hypercoagulability/contiguous inflammation (most commonly, chronic pancreatitis).
● Other complications of cirrhosis: hepatic encephalopathy, ascites, hepatorenal syndrome, spontaneous bacterial peritonitis, hepatocellular carcinoma

DIAGNOSIS
● First indication of varices is often GI bleeding: hematemesis, hematochezia, and/or melena.
● Occult bleeding (anemia): uncommon

HISTORY
● Underlying history of cirrhosis/liver disease. Variceal bleed can be initial presentation of previously undiagnosed cirrhosis.
● Alcohol abuse, exposure to blood-borne viruses through intravenous drug use or sexual practices
● Hematemesis, melena, or hematochezia
● Rapid upper GI bleed can present as rectal bleeding.

PHYSICAL EXAM
● Assess hemodynamic stability: hypotension, tachycardia (active bleeding).
● Abdominal exam—liver palpation/percussion (often small and firm with cirrhosis)
● Splenomegaly, ascites (shifting dullness; fluid shift; puddle splash—physical maneuvers have
limited sensitivity)

- Visible abdominal periumbilical collateral circulation (caput medusae)
- Peripheral stigmata of alcohol abuse: spider angiomata on chest/back, palmar erythema, testicular atrophy, gynecomastia
- Rectal varices
- Hepatic encephalopathy; asterixis
- Blood on rectal exam

**DIFFERENTIAL DIAGNOSIS**

- Upper GI bleeding: 10–30% are due to varices.
  - In patients with known varices, as many as 50% bleed from nonvariceal sources.
  - Peptic ulcer; gastritis
  - Gastric/esophageal malignancy
  - Congestive gastropathy of portal hypertension
  - Arteriovenous malformation
  - Mallory-Weiss tears
  - Aortoenteric fistula
  - Hemoptysis; nosebleed
- Lower GI bleeding
  - Rectal varices; hemorrhoids
  - Colonic neoplasia
  - Diverticulosis/arteriovenous malformation
  - Rapidly bleeding upper GI site
- Continued/recurrent bleeding risk: actively bleeding/large varix, high Child-Pugh severity score, infection, renal failure

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Anemia: Hemoglobin may be normal in active bleeding; may require 6 to 24 hours to equilibrate; other causes of anemia are common in patients with cirrhosis.
- Thrombocytopenia: most sensitive and specific parameter, correlates with portal hypertension, large esophageal varices
- Abnormal aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase, bilirubin; prolonged PT; low albumin suggests cirrhosis.
- BUN, creatinine (BUN often elevated in GI bleed)
- Sodium level; may drop in patients treated with terlipressin

**Esophagogastroduodenoscopy**

- Can identify actively bleeding varices as well as large varices and stigmata of recent bleeding
- Can be used to treat bleeding with esophageal band ligation (preferred to sclerotherapy); prevent rebleeding; detect gastric varices, portal hypertensive gastropathy; diagnose alternative bleeding sites
- Can identify and treat nonbleeding varices (protruding submucosal veins in the distal third of the esophagus)

**Diagnostic Procedures/Other**

- Transient elastography (TE) for identifying CLD patients at risk of developing clinically
significant portal hypertension (CSPH) (1)[A]

- HVPG >10 mm Hg: gold standard to diagnose CSPH (normal: 1 to 5 mm Hg) (1)[A]
- HVPG response of ≥10% or to ≤12 mm Hg to intravenous propranolol identifies responders to nonselective β-blocker (NSBB) and is linked to a decreased risk of variceal bleeding (1,2)[A].
- Video capsule endoscopy screening as an alternative to traditional endoscopy
- Doppler sonography (second line): demonstrates patency, diameter, and flow in portal and splenic veins, and collaterals; sensitive for gastric varices; documents patency after ligation or transjugular intrahepatic portosystemic shunt (TIPS)
- CT- or MRI-angiography (second line, not routine): demonstrates large vascular channels in abdomen, mediastinum; demonstrates patency of intrahepatic portal and splenic vein
  - Venous-phase celiac arteriography: demonstrates portal vein and collaterals; hepatic vein occlusion
  - Portal pressure measurement using retrograde catheter in hepatic vein

**TREATMENT**

**GENERAL MEASURES**

- Treat underlying cirrhotic comorbidities.
- Variceal bleeding is often complicated by hepatic encephalopathy and infection.
- Active bleeding (3)[A]
  - IV access, hemodynamic resuscitation
  - Type and crossmatch packed RBCs. Overtransfusion increases portal pressure and increases rebleeding risk.
  - Treat coagulopathy as necessary. Fresh frozen plasma may increase blood volume and increase rebleeding risk.
  - Avoid sedation, monitor mental status, and avoid nephrotoxic drugs and β-blockers acutely.
  - IV octreotide to lower portal venous pressure as adjuvant to endoscopic management; IV bolus of 50 μg followed by drip of 50 μg/hr
  - Terlipressin (alternative): 2 mg q4h IV for 24 to 48 hours and then 1 mg q4h
  - Erythromycin 250 mg IV 30 to 120 minutes before endoscopy (1)[A]
  - Urgent upper GI endoscopy for diagnosis and treatment
    - Variceal band ligation preferred to sclerotherapy for bleeding varices; also for nonbleeding medium-to-large varices to decrease bleeding risk
    - Ligation: lower rates of rebleeding, fewer complications, more rapid cessation of bleeding, higher rate of variceal eradication
  - Repeat ligation/sclerosant for rebleeding.
  - If endoscopic treatment fails, consider self-expanding esophageal metal stents or per oral placement of Sengstaken-Blakemore–type tube up to 24 hours to stabilize patient for TIPS (1) [C].
- As many as 2/3 of patients with variceal bleeding develop an infection, most commonly spontaneous bacterial peritonitis, UTI, or pneumonia; antibiotic prophylaxis with oral norfloxacin 400 mg or IV ceftriaxone 1 g q24h for up to a week
- In active bleeding, avoid β-blockers, which decrease BP and blunt the physiologic increase in heart rate during acute hemorrhage.
- Prevent recurrence of acute bleeding.
– Vasoconstrictors: terlipressin, octreotide (reduce portal pressure)
– Endoscopic band ligation (EBL): if bleeding recurs/portal pressure measurement shows portal pressure remains >12 mm Hg
– TIPS: second-line therapy if above methods fail; TIPS decreases portal pressure by creating communication between hepatic vein and an intrahepatic portal vein branch.

**MEDICATION**

**Primary prevention of variceal bleeding (4)[A]**

- **Endoscopy:** assesses variceal size, presence of red wale sign (longitudinal variceal reddish streak that suggests either a recent bleed or a pending bleed) to determine risk stratification. F1 varices are small and straight; F2 varices are enlarged and tortuous—occupying less than one-third of the esophageal lumen; F3 varices are enlarged, coiled in appearance and occupy over a third of the esophageal lumen. F2 and F3 varices are managed similarly.
- **Primary prophylaxis:**
  - (1) non-selective β-blocker (NSBB);
  - (2) endoscopic variceal ligation (EVL)

- **Endoscopy every 2 to 3 years if cirrhosis but no varices; every 1 to 2 years if small varices and not receiving β-blockers (2)[A]**

**First Line**

- **Not actively bleeding.** NSBB reduce portal pressure and decrease risk of first bleed from 25% to 15% when used as primary prophylaxis; beneficial in cirrhosis with small varices and increased hemorrhage risk as well as cirrhosis with medium-to-large varices (2,4)[A]
- **Carvedilol:** 6.25 mg daily (2)[A] is more effective than NSBB in dropping HVPG (1)[A].
  - Propranolol: 20 mg BID increase until heart rate decreased by 25% from baseline
  - Nadolol 80 mg daily; increase as above
  - **Contraindications:** severe asthma

- **Chronic prevention of rebleeding (secondary prevention):** NSBBs and EBL reduce rate of rebleeding to a similar extent, but β-blockers reduce mortality, whereas ligation does not (5) [A].

**Second Line**

- Obliterate varices with esophageal ligation if not tolerant of medication prophylaxis.
  - **During ligation:** proton pump inhibitors, such as lansoprazole 30 mg/day, until varices obliterated
  - Management of Budd-Chiari syndrome: anticoagulation, angioplasty/thrombolysis, TIPS, and orthotopic liver transplantation (1)[C]
  - Management of EHPVO: anticoagulation (1)[B]; mesenteric-left portal vein bypass (Meso-Rex procedure) (1)[C]

**ISSUES FOR REFERRAL**

Refer for endoscopy, liver transplant, and interventional radiology for TIPS.

**ADDITIONAL THERAPIES**

Pneumococcal and hepatitis A/B vaccine (HAV/HBV)

**SURGERY/OTHER PROCEDURES**

- Esophageal transection: in rare cases of uncontrollable, exsanguinating bleeding
- Liver transplantation
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inpatient to stabilize acute bleeding and hemodynamic status, therapeutic endoscopy. ICU is typically the most appropriate initial setting.
- Discharge criteria: bleeding cessation, hemodynamic stability, and appropriate plan for treating comorbidities

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Close monitoring of vital signs
- Endoscopic variceal ligation, every 1 to 4 weeks, until varices eradicated
- If TIPS, repeat endoscopy to assess rebleeding.
- Endoscopic screening in patients with known cirrhosis every 2 to 3 years; yearly in patients with decompensated cirrhosis (1)[C]
- Patients with a liver stiffness <20 kPa and with platelets >150,000 can avoid endoscopic screening (1)[A] and may follow up by annual TE and platelet count (1)[C].

PATIENT EDUCATION

National Digestive Diseases Information Clearinghouse (http://www.niddk.nih.gov/health-information/health-topics/digestive-diseases/Pages/default.aspx) or American Liver Foundation (http://www.liverfoundation.org/)

PROGNOSIS

- Depends on underlying comorbidities
- In cirrhosis, 1-year survival is 50% for those who survive at least 2 weeks following a variceal bleed.
- In-hospital mortality remains high and is related to severity of underlying cirrhosis, ranging from 0% in Child-Pugh class A disease to 32% in Child-Pugh class C disease (3).
- Prognosis in noncirrhotic portal fibrosis is better than for cirrhotic portal fibrosis.

COMPLICATIONS

- Formation of gastric varices after eradication of esophageal varices
- Esophageal varices can recur.
- Hepatic encephalopathy, renal dysfunction, hepatorenal syndrome
- Infections after banding/ligation of varices

Cirrhosis of the Liver; Portal Hypertension

CODES

ICD10

- I85.00 Esophageal varices without bleeding
- I85.01 Esophageal varices with bleeding
- I85.10 Secondary esophageal varices without bleeding

CLINICAL PEARLS

- Thrombocytopenia is the most sensitive marker of increased portal pressure and large esophageal varices.
- Roughly half of all patients with cirrhosis will have esophageal varices. One in three of those patients with varices will experience a variceal bleed.
- The risk of bleeding relates directly to the size and appearance of the esophageal varices.
- β-blockers (nadolol; propranolol; carvedilol) act to reduce pressure in the portal circulation and are the preferred pharmacologic choice for primary prevention of variceal bleeding.
- In acute bleeding, avoid β-blockers.
- In acute bleeding, overtransfusion can elevate portal pressure and increase bleeding risk.
ESSENTIAL TREMOR SYNDROME
Jennifer E. Svarverud, DO ● Pamela R. Hughes, MD

BASICS

DESCRIPTION
- A postural (occurring with voluntary maintenance of a position against gravity) or kinetic (occurring during voluntary movement) flexion–extension tremor that is slow and rhythmic and primarily affects the hands, forearms, head, or voice with a frequency of 4 to 12 Hz
- Older patients tend to have lower frequency tremors, whereas younger patients exhibit frequencies in the higher range.
- May be familial, sporadic, or associated with other movement disorders
- Incidence and prevalence increase with age, but symptom onset can occur at any age.
- The tremor can be intermittent and exacerbated by emotional or physical stressors, fatigue, and caffeine.
- System(s) affected include neurologic, musculoskeletal, ear/nose/throat (ENT) (voice)

EPIDEMIOLOGY

Essential tremor is the most common pathologic tremor in humans.

Incidence
- Can occur at any age but bimodal peaks exist in the 2nd and 6th decades
- Incidence rises significantly after age 49 years.

Prevalence
The overall prevalence for essential tremor has been estimated between 0.4% and 0.9% but is increased in older patients with an estimated prevalence of 4.6% at age 65 years and up to 22% at age 95 years.

ETIOLOGY AND PATHOPHYSIOLOGY
- Suspected to originate from an abnormal oscillation within thalamocortical and cerebello-olivary loops, as lesions in these areas tend to reduce essential tremor
- Essential tremor is not a homogenous disorder; many patients have other motor manifestations and nonmotor features, including cognitive and psychiatric symptoms.

Genetics
- Positive family history in 50–70% of patients; autosomal-dominant inheritance is demonstrated in many families with poor penetrance. Twin studies suggest that environmental factors are also involved.
- A link to genetic loci exists on chromosomes 2p22–2p25, 3q13, and 6p23. In addition, a Ser9Gly variant in the dopamine D3 receptor gene on 3q13 has been suggested as a risk factor.

COMMONLY ASSOCIATED CONDITIONS
- Can be present in 10% of patients with Parkinson disease (PD); characteristics of PD that distinguish it from essential tremor include 3- to 5-Hz resting tremor; accompanying rigidity, bradykinesia, or postural instability; and no change with alcohol consumption
- Patients with essential tremor have a 4% risk of developing PD.
Resting tremor, typically of the arm, may be seen in up to 20–30% of patients with essential tremor. Although action tremor is the hallmark feature of essential tremor, it is commonly found in patients with PD as well.

**DIAGNOSIS**

**HISTORY**
- Core criteria for diagnosis
  - “Bilateral (less likely unilateral) action (postural or kinetic) tremor of the hands and forearms that is most commonly asymmetric
  - “Absence of other neurologic signs, with the exception of cogwheel phenomenon
  - “May have isolated head tremor with no signs of dystonia
- Secondary criteria include long duration (>3 years), positive family history, and beneficial response to alcohol.

**PHYSICAL EXAM**
- Tremor can affect upper limbs (~95% of patients).
- Less commonly, the tremor affects head (~34%), lower limbs (~30%), voice (~12%), tongue (~7%), face (~5%), and trunk (~5%).

**DIFFERENTIAL DIAGNOSIS**
- PD Enhanced physiologic tremor
- Wilson disease
- Hyperthyroidism
- Multiple sclerosis
- Dystonic tremor
- Cerebellar tremor
- Asterixis
- Psychogenic tremor
- Orthostatic tremor
- Drug-induced or enhanced physiologic tremor (amiodarone, cimetidine, lamotrigine, itraconazole, valproic acid, selective serotonin reuptake inhibitors, steroids, lithium, cyclosporine, β-adrenergic agonists, ephedrine, theophylline, tricyclic antidepressants [TCAs], antipsychotics)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- No specific biologic marker or diagnostic test is available.
- Ceruloplasmin and serum copper to rule out Wilson disease
- Thyroid-stimulating hormone to rule out thyroid dysfunction
- Serum electrolytes, blood urea nitrogen, creatinine
- Brain magnetic resonance imaging (MRI) usually is not necessary or indicated unless Wilson disease is found or exam findings imply central lesion.

**Diagnostic Procedures/Other**
- Accelerometry evaluates tremor frequency and amplitude; >95% of PD cases exhibit frequencies in the 4- to 6-Hz range, and 95% of essential tremor cases exhibit frequencies in
the 5- to 8-Hz range.

- Surface electromyography is less helpful in distinguishing essential tremor from PD.

**Test Interpretation**
Posture-related tremor seen on exam

---

**TREATMENT**

**MEDICATION**
Pharmacologic treatment should be considered when tremor interferes with activities of daily living (ADLs) or causes psychological distress.

**First Line**
- Propranolol 60 to 320 mg/day in divided doses or in long-acting formulation reduces limb tremor magnitude by ~50%, and almost 70% of patients experience improvement in clinical rating scales. There is insufficient evidence to recommend propranolol for vocal tremor. Single doses of propranolol, taken before social situations that are likely to exacerbate tremor, are useful for some patients.
- Primidone 25 mg at bedtime, gradually titrated to 150 to 300 mg at bedtime, improves tremor amplitude by 40–50%. Maximum dose is 750 mg/day, with doses >250 mg/day typically divided to BID or TID. Low-dose therapy (<250 mg/day) is just as effective as high-dose (750 mg/day) therapy.

- Propranolol and primidone have similar efficacy when used as initial therapy for limb tremor; both carry a level A recommendation [1][A].
- 30–50% of patients will not respond to either propranolol or primidone.

**Second Line**
- Topiramate at a mean dose of 292 mg/day demonstrated significantly greater reduction in Tremor Rating Scale (TRS) compared with placebo (7.70 vs. 0.08; p < .005; baseline TRS = 37.0) in a small study combining results of three double-blind, randomized, controlled trials following a common protocol. Use is limited by dropout rates as high as 40% due to appetite suppression, weight loss, paresthesias, and concentration difficulties [2][B].
- Gabapentin up to 400 mg TID [3][B]
- Sotalol, nadolol, and atenolol are alternative β-blockers; each has less evidence than propranolol to support use.
- Clonazepam and alprazolam should be used with caution because of potential abuse.
- Clozapine has shown efficacy at doses of 6 to 75 mg/day but is recommended only for refractory cases of limb tremor because of a 1% risk of agranulocytosis. The American Academy of Neurology (AAN) indicates that insufficient evidence exists to support or refute the efficacy of clozapine for chronic use [1][A].
- Memantine, in a pilot study using doses up to 40 mg/day, showed significant benefit in a small subset of the study group. Adverse events at this dose included dizziness, somnolence, and poor energy [4][B].
- Pramipexole, at a dose of 2.1 mg/day, demonstrated moderate efficacy in reducing severity of tremor in a pilot study of 29 patients. Immediate- and extended-release formulations were equally effective [5][B].
Levetiracetam and 3,4-diaminopyridine are probably ineffective at reducing limb tremor and should not be considered according to the AAN (1)[A].
Other medications that have been evaluated for treatment of essential tremor, with limited data to support their use, include acetazolamide, clonidine, flunarizine, methazolamide, nimodipine, olanzapine, phenobarbital, pregabalin, quetiapine, sodium oxybate, and zonisamide (1)[A].
Alcohol may provide transient improvement in symptoms, but its brief duration of action, subsequent rebound, and associated risk of developing alcohol addiction make it a less attractive option for longer term treatment. Alcohol may be an appropriate option for short-term, situation-specific improvement in symptoms.
Botulinum toxin A injections should be offered as a treatment option for cervical dystonia (level A recommendation from AAN) and may be offered for blepharospasm, focal upper extremity dystonia, adductor laryngeal dystonia, and upper extremity essential tremor. Limited data support its use for head and vocal tremor (6)[B].

ISSUES FOR REFERRAL
Referral to a neurologist can help to differentiate those with dystonia, neuropathic tremor, PD, or drug-induced tremor.

SURGERY/OTHER PROCEDURES
- Deep brain stimulation provides a magnitude of benefit that is superior to all available medications and may be used to treat medically refractory limb tremor; it has fewer adverse effects than thalamotomy.
- Bilateral thalamic stimulation is effective in reducing tremor and functional disability; however, dysarthria is a possible complication.
- Unilateral thalamotomy may be used to treat limb tremor that is refractory to medical management.
- Bilateral thalamotomy is not recommended because of adverse side effects.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Physical therapy may be considered for strengthening and training in use of weighted utensils to help offset tremor. Although strength training has not been shown to have improvement in functional ability, no negative effects have been reported.

ONGOING CARE

DIET
Avoid caffeine.

PATIENT EDUCATION
Although essential tremor can cause significant impairment in daily functioning, it does not decrease life expectancy.

PROGNOSIS
Tremor tends to worsen with age, increasing in amplitude.
REFERENCES

ADDITIONAL READING

CODES

ICD10
G25.0 Essential tremor
CLINICAL PEARLS

- Core criteria for diagnosis of essential tremor include bilateral action or postural tremor of the hands, forearm, and/or head without a resting component.
- Beneficial response to alcohol and positive family history help to differentiate essential tremor from PD. (PD is characterized by tremor at rest, bradykinesia, and rigidity, and it does not improve with alcohol use.)
- 10% of patients with PD will have both resting tremors of PD and essential tremor.
- Wilson disease, thyroid disease, and medication effect should be ruled out.
- Brain MRI is usually not necessary or indicated.
- First-line treatments include propranolol and primidone. 30–50% of patients will not benefit from these first-line treatments.
EUSTACHIAN TUBE DYSFUNCTION

Kathryn L. Collins, DO ● Jacob M. Burdett, DO

BASICS

The eustachian tube (ET), also known as the auditory or pharyngotympanic tube, is a 35 mm × 3 mm structure that connects the posterior nasopharynx to the middle ear. The proximal 2/3 of the ET is composed of cartilage, while the distal 1/3 closest to the middle ear is made of bone. Its primary function is to equilibrate pressure within the middle ear to atmospheric pressure. It also ventilates and drains the middle ear space, which prevents and clears infection and debris. When the ET malfunctions by either becoming too dilated (patulous dysfunction) or occluded (obstructive dysfunction) it results in eustachian tube dysfunction (ETD).

DESCRIPTION

- A spectrum of disorders involving impairment of the functional valve of the ET
- ETD can be classified as patulous dysfunction, in which the ET is excessively open, or dilatory dysfunction, in which there is failure of the tubes to dilate (i.e., open) appropriately.
- Pathophysiology related to pressure dysregulation, impaired protection secondary to reflux of irritating material into the middle ear, or impaired clearance by the mucociliary system
- May occur in the setting of pressure changes (e.g., scuba diving or air travel) or acute upper airway inflammation (e.g., allergic or infectious rhinosinusitis, acute otitis media [OM])
- Chronic ETD may lead to a retracted tympanic membrane, recurrent serous effusion, recurrent OM, adhesive OM, chronic mastoiditis, or cholesteatoma.

- System(s) affected: auditory
- Synonym(s): auditory tube dysfunction; ET disorder; blocked ET; patulous ET

ALERT

- Sudden sensorineural hearing loss (SSNHL) can be misdiagnosed as ETD.
- A simple 512-Hz tuning fork test lateralizes to the opposite ear in SSNHL and to the affected ear in ETD with conductive hearing loss.
- Any SSNHL is a medical emergency and should be referred to an otolaryngologist immediately.

EPIDEMIOLOGY

Adults: over 2 million health care visits annually
- Median age: 48 years
- Females > males
- Most common comorbidity is acute rhinitis

ETIOLOGY AND PATHOPHYSIOLOGY

- Under normal circumstances, the ET is closed, opening to release a small amount of air to equilibrate middle ear pressure with surrounding atmospheric pressure.
- ETD is failure of the ET, palate, nasal cavities, and nasopharynx to regulate middle ear and mastoid pressure.
- ET functions:
  - Ventilation/regulation of middle ear pressure
– Protection from nasopharyngeal secretions
– Drainage of middle ear fluid
– ET is closed at rest and opens with yawning, swallowing, and chewing.

Cycle of dysfunction: structural or functional obstruction of the ET:
– Negative pressure develops in middle ear.
– Serous exudate is drawn to the middle ear by negative pressure or refluxed into the middle ear if the ET opens momentarily.
– Infection of static fluid causes edema and release of inflammatory mediators, exacerbating the cycle of inflammation and obstruction.

● In children, a horizontal and shorter ET predisposes to difficulties with ventilation and drainage.
● Adenoid hypertrophy can block the torus tubarius (proximal opening of the ET).
● In adults, paradoxical closing of the ET with swallowing occurs in a majority of affected patients.
● Tumors that impair/occlude the ET or that invade the tensor veli palatini to impair normal swallow regulation, can also lead to dysfunction.

Genetics
Twin studies show a genetic component. Specific genetic cause is undefined.

RISK FACTORS
Adult and pediatric:
● Allergic rhinitis, tobacco exposure, gastroesophageal reflux disease (GERD), chronic sinusitis, adenoid hypertrophy or nasopharyngeal mass, neuromuscular disease, altered immunity
● Prematurity and low birth weight, young age, daycare, crowded living conditions, low socioeconomic status, prone sleeping position, prolonged bottle use, craniofacial abnormalities (e.g., cleft palate, Down syndrome)

Pregnancy Considerations
ETD may be exacerbated by rhinitis of pregnancy; symptoms resolve postpartum.

GENERAL PREVENTION
● Control of upper airway inflammation: allergies, infectious rhinosinusitis, GERD
● Autoinsufflation of middle ear (i.e., blow gently against pinched nostril and closed mouth)
● Avoid atmospheric pressure changes (e.g., plane flight, scuba diving) in the setting of acute allergy exacerbation or (upper respiratory infection [URI]).
● Avoid exposure to environmental irritants: tobacco smoke and pollutants.

COMMONLY ASSOCIATED CONDITIONS
● Hearing loss
● OM: acute, chronic, and serous
● Chronic mastoiditis
● Cholesteatoma
● Allergic rhinitis
● Chronic sinusitis/URI
● Adenoid hypertrophy
● GERD
● Cleft palate
● Down syndrome
● Obesity
● Nasopharyngeal carcinoma or other tumor

DIAGNOSIS

HISTORY
● Symptoms of ear pain, fullness, “plugging,” hearing loss, tinnitus, popping or snapping noises, and vertigo
  – Unilateral or bilateral. Evaluate adults with persistent unilateral symptoms for nasopharyngeal tumor.
  – History of previous ear infections, surgeries, head trauma, recent flying or diving
  – Voice change (hypo- or hypernasal voice, consider NP mass or palatal dysfunction)
  – Differentiate patulous dysfunction, in which patient’s own voice and breath sounds are amplified (autophony), from dilatory dysfunction, in which patient complains more of ear pain, “plugged” ear, hearing loss, and tinnitus.

Eustachian Tube Dysfunction Questionnaire is a questionnaire that attempts to quantify ETD in adult patients. Based on presence and intensity of symptoms in past 1 month, severity is rated on 1 to 7 scale. A total score >14.5 categorizes patient as having ETD (1)[B],(2)[B].
  – Pressure in ears in past 1 month?
  – Pain in ears in past 1 month?
  – A feeling that ears are clogged or “under water”?
  – Ear symptoms when you have cold or sinusitis?
  – Crackling or popping sounds in the ears?
  – Ringing in ears?
  – A feeling that your hearing is muffled?

PHYSICAL EXAM
● Pneumatic otoscopy: retracted tympanic membrane, effusion, decreased drum movement
● Toynbee maneuver: View changes of the drum while patient autoinsufflates against closed lips and pinched nostrils; may show various degrees of retraction
  – Entire drum may be retracted and “lateralize” with insufflation.
  – Posterosuperior quadrant (pars flaccida) may form a retraction pocket.
● Tuning fork tests: 512-Hz fork placed on the forehead lateralizes to affected ear (Weber test); the fork will be louder behind the ear on the mastoid than in front of the ear (bone conduction > air conduction, Rinne test) in conductive hearing loss.
● Nasopharyngoscopy: adenoid hypertrophy or nasopharyngeal mass
● Anterior rhinoscopy: deviated nasal septum, polyp, mucosal hypertrophy, turbinate hypertrophy

DIFFERENTIAL DIAGNOSIS
● SSNHL (a medical emergency)
● Tympanic membrane perforation
● Barotrauma
● Temporomandibular joint disorder
● Ménière disease
Superior semicircular canal dehiscence

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- No routine radiologic studies needed if clinical signs/symptoms suggest ETD
- CT scan (not necessary) may show changes related to OM or middle ear/mastoid opacification.
- Functional MRI might determine cause of ETD (in recalcitrant cases), as the ET opening can be visualized during Valsalva.

**Diagnostic Procedures/Other**
- Audiogram may show conductive hearing loss.
- Tympanometry: Type B or C tympanograms indicate fluid or retraction, respectively; negative middle ear peak pressures seen even with normal (type A) tympanograms

**TREATMENT**
- Due to limited high-quality evidence, it is difficult to recommend any one treatment option/intervention as superior (3)[C].
- Use of a “nasal balloon” shown effective for clearing OM with effusion; unclear of benefit for ETD
- General principle is to remove or fix the underlying cause (e.g., infection, tumor, perforation of TM, restore tensor palatini muscle) and reduce or eliminate the cycle of infection/inflammation.
- Although no evidence exists, some consider antibiotics for acute otitis media; decongestants, nasal steroids, antihistamines (if allergic rhinitis is present), and surgery/procedures for recalcitrant cases
- Tympanostomy tubes ± adenoidectomy when indicated for recurrent ear infections or severe progressive retractions

**MEDICATION**
- Antibiotics only if infection is suspected as cause of ETD (4)[A]
- Few data support pharmacologic treatments such as decongestants, nasal steroids, or antihistamines for ETD.
- Medications treat comorbid conditions.
- Decongestants, topical, oral
  - Avoid prolonged use (>3 days); can cause rhinitis medicamentosa
  - Decongestants are most useful for acute ETD related to a resolving URI.
  - Decongestants are not typically used for relief of chronic ETD in children.
    - Phenylephrine: adults and children ≥12 years of age, 1 tablet (10 mg) q4h PRN; children 6 to 11 years of age, 5 mg q4h PRN; children 4 to 5 years of age, 2.5 mg q4h PRN
    - Pseudoephedrine: adults, 60 mg q4–6h PRN; children 6 to 12 years of age, 30 mg q4–6h PRN; children 4 to 5 years of age, 15 mg q4–6h PRN
    - Oxymetazoline: adults and children ≥6 years of age, 1 to 2 sprays each nostril q12h PRN. Limit use to ≤3 days.
      - Phenylephrine: adults, 1 to 2 sprays each nostril q4h PRN. Limit use to ≤3 days.
- Nasal steroids (may be beneficial for those with allergic rhinitis) (5)[A]
– Beclomethasone (Beconase, Vancenase): adults and children ≥12 years of age, 1 to 2 sprays each nostril BID; children 6 to 11 years of age, 1 spray each nostril BID; not recommended for children <6 years of age
– Budesonide (Rhinocort): adults and children ≥6 years of age, 1 spray each nostril daily
– Ciclesonide (Omnaris) (a prodrug activated on nasal mucosa): adults and children ≥6 years of age, 2 sprays each nostril daily
– Flunisolide (Nasarel, Nasalide): adults and children ≥6 years of age, 2 sprays each nostril daily
– Fluticasone furoate (Veramyst): adults and children ≥12 years of age, 2 sprays each nostril daily; children 2 to 11 years of age, 1 spray each nostril daily
– Fluticasone propionate (Flonase): adults 1 to 2 sprays each nostril daily; children ≥4 years of age, 1 spray each nostril daily
– Mometasone (Nasonex): adults and children ≥12 years of age, 2 sprays each nostril daily; children 2 to 12 years of age, 1 spray each nostril daily
– Triamcinolone (Nasacort): adults and children ≥6 years of age, 1 to 2 sprays each nostril daily; children 2 to 5 years of age, 1 spray each nostril daily

• 2nd-generation H1 antihistamines (may be beneficial for those with ETD and chronic rhinitis)
– Cetirizine (Zyrtec) (tablets, chewable tablets, liquid): adults and children ≥6 years of age, 5 to 10 mg/day PO; children 12 months to 5 years of age: 2.5 mg/day PO, may increase to BID; children 6 to <12 months of age: 2.5 mg/day PO
– Desloratadine (Clarinex) (tablets, RediTabs, liquid): adults and children ≥12 years of age, 5 mg/day PO; children 6 to 11 years of age, 2.5 mg/day PO; children 12 months to 5 years of age, 1.25 mg/day PO; children 6 to 11 months of age, 1 mg/day PO
– Fexofenadine (Allegra) (tablets, RediTabs, liquid): adults and children ≥12 years of age, 60 mg PO BID or 180 mg/day PO; children 2 to 11 years of age, 30 mg PO BID
– Levocetirizine (Xyzal) (tablets, liquid): adults and children ≥12 years of age, 2.5 to 5.0 mg PO every evening; children 6 to 11 years of age, 2.5 mg PO every evening; children 6 months to 5 years of age, 1.25 mg PO every evening

• Antihistamine nasal sprays (may be beneficial for those with ETD and chronic rhinitis)
– Azelastine (Astepro or Astelin): adults and children ≥12 years of age, 1 to 2 sprays each nostril BID; children 6 to 11 years of age, 1 spray each nostril BID
– Olopatadine (Patanase): adults and children ≥12 years of age, 2 sprays each nostril BID; children 6 to 11 years of age, 1 spray each nostril BID

ADDITIONAL THERAPIES
• Any activity that promotes swallowing, such as chewing gum, eating, or drinking, can open the ET and promote relief of symptoms.
• Patients with ETD should refrain from flying during times of nasal congestion or ear infection. If the patient must fly, advise them to take oral and intranasal decongestants an hour prior to take off.
• Patients should refrain from scuba diving.

SURGERY/OTHER PROCEDURES
• Myringotomy and pressure equalization tube placement to ventilate middle ear, relieve pressure, and prevent sequelae of chronically retracted drum
• Patients with ETD during pressure changes may benefit from minimally invasive laser eustachian tuboplasty.
Balloon tuboplasty (limited data in terms of efficacy, safety, and long-term outcomes) (6)[B]

Adenoidectomy if hypertrophied tissue is present
- In children, first set of tubes are typically placed alone. Adenoidectomy is performed with second set of tubes if problems recur.
- Some advocate adenoidectomy even in absence of excess tissue; reduces frequency and number of subsequent tubes

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Osteopathic manipulative treatment (OMT) can be utilized in the treatment of ETD.
- Galbreath technique

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Monitor pressure equalization tubes every 6 to 8 months in children and every 6 to 12 months in adults.
- Monitor tympanic membrane retraction pocket for progression every 6 to 12 months to allow for early intervention for progression in hearing loss, obvious ossicular erosion, or cholesteatoma.

DIET
Breastfeeding is associated with lower incidence of ETD and OM.

PROGNOSIS
If symptoms of ETD persist beyond age 7 years, patient is more likely to have long-term problems and require regular monitoring.

COMPLICATIONS
Morbidity related to hearing compromise or associated sequela of chronic ear infections

Algorithm: Ear Pain/Otalgia

CODES

ICD10

- H69.90 Unspecified Eustachian tube disorder, unspecified ear
- H69.00 Patulous Eustachian tube, unspecified ear
- H68.109 Unspecified obstruction of Eustachian tube, unspecified ear

CLINICAL PEARLS

- ETD can be acute or chronic. Treatment is based on the underlying etiology.
- Rule out SSNHL (medical emergency), which can be misdiagnosed as ETD, especially in patients with unilateral symptoms.
FACTOR V LEIDEN

Christy L. Baggett, DO ● Collin R. Jones, MD ● George G.A. Pujalte, MD, FACSM

BASICS

DESCRIPTION
- Factor V Leiden is a genetic mutation at the activated protein C (APC) cleavage site on the factor V and Va molecule leading to the most common form of inherited thrombophilia.
- System(s) affected: cardiovascular, gastrointestinal, hemo/lymphatic/immunologic, nervous, pulmonary, reproductive
- Synonym(s): factor V Leiden thrombophilia; factor V Leiden mutation, hereditary APC resistance

Pediatric Considerations
Potential for increased thrombosis risk in patients with factor V Leiden and concomitant risks

Pregnancy Considerations
- Recurrent pregnancy loss is a possible complication.
- Increased thrombotic risk in pregnancy and postpartum (additive) especially in homozygous state
- Possible increased risk of IUGR, preeclampsia, placental abruption: evidence mixed
- Women with a history of adverse pregnancy outcomes should be tested for thrombophilia if they are planning a future pregnancy (1).

EPIDEMIOLOGY

Prevalence
Studies estimate ~5–8% occurrence of heterozygosity in Caucasians, Hispanic Americans ~2%, African American ~1%, and Asian Americans ~0.45%.

ETIOLOGY AND PATHOPHYSIOLOGY
- Factor V circulates in the plasma. When exposed to tissue factor, factor V amplifies the production of thrombin, which further promotes clotting by activating factor V into procoagulant factor Va.
- For balance, thrombin also promotes APC production, which will cleave and inactivate factor V, Va, and VIII, thereby keeping the clotting cascade in check (negative feedback loop).
- In factor V Leiden, a point mutation at the binding site of APC (Arg506Glu) renders it less able to cleave factor V or Va. This, in turn, reduces the anticoagulant role of factor V as a cofactor to APC and increases the procoagulant role of activated factor V because there is now 20-fold slower degradation of factor Va.

RISK FACTORS
- Risk for venous thromboembolism (VTE) is ~7-fold in heterozygous and ~80-fold in homozygous factor V Leiden individuals, compared with individuals without the mutation (2). This risk is compounded/increased by the presence of the following:
  - Having non-O blood type (A, B, or AB): 2- to 4-fold
– Oral contraceptives: homozygotes up to 100-fold; heterozygotes, 35-fold. The increased risk is halved when the patient uses desogestrel-containing oral contraceptives.
– Hormone replacement therapy (HRT) and selective estrogen receptor modulators (SERMs) both increase the risk of thrombosis; in patients with factor V Leiden, that risk is compounded.
– In men with an underlying thrombophilia, testosterone therapy can promote VTE (3).
– Pregnancy and homozygous factor V Leiden increase the risk of thrombosis 7- to 16-fold during pregnancy and the puerperium.
– Those with combined thrombophilias and end-stage renal disease are at risk for developing calciphylaxis (4).

Data are conflicting with regard to risk for recurrent VTE for patients with factor V Leiden but trend toward an increased risk (5,6).

GENERAL PREVENTION

ALERTr
Patients with factor V Leiden without thrombosis do not require prophylactic anticoagulation.

COMMONLY ASSOCIATED CONDITIONS
Venous thrombosis

DIAGNOSIS

HISTORY
● Previous thrombosis
● Family history of thrombosis

PHYSICAL EXAM
● Family history of factor V Leiden mutation
● Findings suggestive of VTE in any form (DVT, PE, cerebral thrombosis): 10–26% of patients with VTE are carriers of the factor V Leiden mutation.
● Thrombosis in unusual locations, such as the sagittal sinus or mesentery and portal systems, although these are less common in patients with factor V Leiden than in patients with deficiency of protein C or S
● There is a weak, however significant, association between procoagulant states (including factor V Leiden) and coronary events in younger patients (4).

DIFFERENTIAL DIAGNOSIS
● Protein C deficiency
● Protein S deficiency
● Antithrombin deficiency
● Other causes of APC resistance (e.g., antiphospholipid antibodies)
● Dysfibrinogenemia
● Dysplasminogenemia
● Homocystinemia
● Prothrombin 20210 mutation
● Elevated factor VIII levels
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- For evaluation of a new clot in patient at risk: CBC with peripheral smear, PT/INR, activated partial thromboplastin time (aPTT), thrombin time, lupus anticoagulant, antiphospholipid antibodies, factor VIII, anticardiolipin antibody, anti-β2 glycoprotein I antibody, APC resistance, protein S antigen and resistance, antithrombin III assay, fibrinogen, factor V Leiden, prothrombin G20210A
- Genetic test: DNA-based test for factor V mutation; will be unaffected by anticoagulation and other drugs
- Functional test: plasma-based coagulation assay using factor V–deficient plasma to which patient plasma is added along with purified APC. The relative prolongation of the aPTT is used to assay for the defect. Heparin, direct thrombin inhibitors, and factor Xa inhibitor may cause false-negative results. In the absence of exposure to anticoagulants, functional testing is preferred to genetic testing due to cost and time to diagnosis (5) [A].
- Extremity US for DVT
- V/Q scan or spiral CT for PE

Follow-Up Tests & Special Considerations
- US may not show DVT acutely; repeat in 5 to 7 days if strong suspicion.
- V/Q scan for evaluation of PE may be difficult to interpret in smokers or those with underlying lung disease.

Diagnostic Procedures/Other
- Magnetic resonance angiography (MRA), venography, or arteriography to detect thrombosis

TREATMENT

Only indicated if with thrombotic event

GENERAL MEASURES
- Like general VTE treatment, patients with factor V Leiden and a first thrombosis should be anticoagulated initially with heparin or low-molecular-weight heparin (LMWH) and warfarin for at least 3 months.
- Factor Xa inhibitors are FDA-approved for VTE/PE prophylaxis and treatment in patients without kidney disease. These have the benefit of not requiring lab monitoring or dietary limitations. For patients with factor V Leiden and recurrence of DVT/PE, factor Xa inhibitors are indicated for prophylaxis (7).
- Treatment with LMWH is recommended over unfractionated heparin, unless the patient has severe renal failure (6) [A].
- Treat as outpatient, if possible (6) [A].
- Initiate warfarin with LMWH on the first treatment day and discontinue LMWH after minimum of 5 days and when INR >2 for 2 consecutive days (6) [A].
- Patients should be maintained on warfarin with an INR of 2 to 3 for at least 3 months (6) [A].
- For those patients with recurrence, the risks and benefits of indefinite anticoagulation need to be assessed and considered.

MEDICATION
First Line

- **LMWH:**
  - Enoxaparin (Lovenox): 1 mg/kg SC BID; start warfarin simultaneously; continue enoxaparin for minimum of 5 days and until INR is >2 for 2 consecutive days, at which time enoxaparin can be stopped.
  - Fondaparinux (Arixtra): 5 mg (body weight <50 kg), 7.5 mg (body weight 50 to 100 kg), or 10 mg (body weight >100 kg) SC daily
  - Tinzaparin (Innohep): 175 anti-Xa IU/kg SC daily for minimum of 5 days and patient is adequately anticoagulated with warfarin (INR of at least 2 for 2 consecutive days)
  - Dalteparin (Fragmin): 200 IU/kg SC daily

- **Oral anticoagulant**
  - Warfarin (Coumadin) PO with dose adjusted to an INR of 2 to 3 (3)[A]
    - Apixaban (Eliquis): treatment dose: 10 mg BID × 7 days and then 5 mg BID × 3 to 6 months. Nonatrial fibrillation DVT prophylaxis: 2.5 mg BID
    - Rivaroxaban (Xarelto): treatment dose: 15 mg BID × 7 days and then 20 mg daily × 3 to 6 months. Nonatrial fibrillation prophylaxis: 10 mg daily

- **Contraindications**
  - Active bleeding precludes anticoagulation.
  - Risk of bleeding is a relative contraindication to long-term anticoagulation.
  - Warfarin is contraindicated in patients with history of warfarin skin necrosis (6)[A].
  - Warfarin is contraindicated in pregnancy.

- **Precautions**
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Avoid IM injections. Periodically check stool and urine for occult blood; monitor CBCs, including platelets.
  - Heparin: thrombocytopenia and/or paradoxical thrombosis with thrombocytopenia
  - Warfarin: necrotic skin lesions (typically breasts, thighs, or buttocks)
  - LMWH: Adjust dosage in renal insufficiency; may also need dose adjustment in pregnancy

- **Significant possible interactions**
  - Agents that intensify the response to oral anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfipyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen
  - Agents that diminish the response to anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

Second Line

- Heparin 80 mg/kg IV bolus followed by 18 g/kg/hr continuous infusion
- Adjust dose depending on aPTT.
- In patients requiring large daily doses of heparin, measure an anti-Xa level for dose guidance.
- Alternatively, for outpatients, weight-adjusted subcutaneous unfractionated heparin with 333 U/kg first and then 250 U/kg, without monitoring (6)[A]

- Consider deficiency of antithrombin as a comutation in patients with significant elevated heparin requirements.

**ISSUES FOR REFERRAL**
Recurrent thrombosis on anticoagulation
Difficulty anticoagulating
Genetic counseling
Homozygous state in pregnancy

SURGERY/OTHER PROCEDURES
Anticoagulation must be held for surgical interventions.
For most patients with DVT, recommendations are against routine use of inferior vena cava filter in addition to anticoagulation, except when there is contraindication for anticoagulation (6)[A].
Thrombectomy may be necessary in some cases.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Admission criteria/initial stabilization: complicated thrombosis, such as PE
Nursing
  – Teach LMWH and warfarin use.
  – See earlier for drug interactions.
Discharge criteria: stable on anticoagulation

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Warfarin use requires periodic (~monthly after initial stabilization) INR measurements, with a goal of 2 to 3 (6)[A].

DIET
No restrictions
Large amounts of foods rich in vitamin K may interfere with anticoagulation with warfarin.

PATIENT EDUCATION
Patients should be educated about the following:
  – Use of oral anticoagulant therapy
  – Avoidance of NSAIDs while on warfarin
The role of family screening is unclear because most patients with this mutation do not have thrombosis. In a patient with a family history of factor V Leiden, consider screening during pregnancy or if considering oral contraceptive use.

PROGNOSIS
Most patients heterozygous for factor V Leiden do not have thrombosis.
Homzygotes have about a 50% lifetime incidence of thrombosis.
Recurrence rates after a first thrombosis are not clear, with some investigators finding rates as high as 5% and others finding rates similar to the general population.
Despite the increased risk for thrombosis, factor V Leiden does not increase overall mortality.

COMPLICATIONS
Recurrent thrombosis
Bleeding on anticoagulation

REFERENCES

ADDITIONAL READING

SEE ALSO

Deep Vein Thrombophlebitis

CODES

ICD10

D68.51 Activated protein C resistance

CLINICAL PEARLS

- Extremely rare in Asian and African populations
- Asymptomatic patients with factor V Leiden do not need anticoagulation.
- For pregnant women homozygous for factor V Leiden but no prior history of VTE, postpartum prophylaxis with prophylactic or intermediate-dose LMWH or vitamin K antagonists with target INR 2 to 3 for 6 weeks is recommended. Antepartum prophylaxis is added if there is...
positive family history of VTE.
Failure to thrive (FTT) is not a diagnosis but a sign of inadequate nutrition in young children manifested by a failure of physical growth, usually affecting weight. In severe cases, decreased length and/or head circumference may develop.

Various parameters are used to define FTT, but in clinical practice, it is commonly defined as either weight or BMI for age that falls below the 5th percentile on more than one occasion or weight that drops two or more major percentile lines on standard growth charts or weight-for-length falls below the 5th percentile.

A combination of anthropometric criteria rather than one criterion should be used to identify children at risk of FTT (1)[C].

**Pediatric Considerations**
- Children with genetic syndromes, intrauterine growth restriction (IUGR), or prematurity follow different growth curves.
- 25% of children will decrease their weight or height crossing ≥2 major percentile lines in the first 2 years of life. These children are failing to reach their genetic potential or demonstrating constitutional growth delay (slow growth with a bone age < chronologic age). After shifting down, these infants grow at a normal rate along their new percentile and do not have FTT.

**Epidemiology**

**Incidence**
- Predominant age: 6 to 12 months; 80% <18 months
- Predominant sex: male = female

**Prevalence**
- As many as 10% of children seen in primary care have signs of growth failure.
- 1–5% of pediatric inpatient admissions are for FTT.
- Occurs more frequently in children living in poverty (1)

**Etiology and Pathophysiology**
- Mismatch between caloric intake and caloric expenditure
- Often grouped into four major categories:
  - Inadequate caloric intake (most frequent)
  - Inadequate caloric absorption
  - Excessive caloric expenditure
  - Defective utilization
- Traditionally, FTT was classified as organic or nonorganic, but most cases are multifactorial.
- FTT often begins with a specific event and may lead to persistent difficulties.
- Causes of FTT can be grouped by pathophysiology (including examples):
  - Inadequate intake: breastfeeding difficulty, incorrect formula preparation, poor transition to food (6 to 12 months), poor feeding habits (e.g., excessive juice, restrictive diets),
mechanical problems (e.g., oromotor dysfunction, congenital anomalies, GERD, CNS, or PNS anomalies), oral aversion, poverty, neglect/abuse, poor parent–child interaction, caregiver feeding style
– Inadequate absorption: necrotizing enterocolitis, short gut syndrome, biliary atresia, liver disease, cystic fibrosis, celiac disease, milk protein allergy, vitamin/mineral deficiency, environmental enteric dysfunction
– Increased expenditure: hyperthyroidism, congenital/chronic cardiopulmonary disease, HIV, immunodeficiencies, malignancy, renal disease, obstructive sleep apnea
– Defective utilization: metabolic disorders, congenital infections (TORCH: toxoplasmosis, other agents, rubella, cytomegalovirus, herpes simplex)

Genetics
Multiple genetic disorders can cause FTT.

RISK FACTORS
• Psychosocial risks (2)
  – Poverty, parent(s) with mental health disorder or cognitive impairment, poor parenting skills or hypervigilant parents, families with unique health/nutritional beliefs, physical or emotional abuse, substance abuse, and social isolation
• Medical risks (2)
  – Intrauterine exposures, history of IUGR (symmetric or asymmetric), congenital abnormalities, oromotor dysfunction, premature or sick newborn, infant with physical deformity, acute or chronic medical conditions, developmental delay, lead poisoning, anemia

Pregnancy Considerations
FTT is linked to intrauterine exposures, IUGR, and prematurity.

GENERAL PREVENTION
• Educate parents on normal feeding and parenting skills.
• Access to supplemental feeding programs (Women, Infants, and Children [WIC])

COMMONLY ASSOCIATED CONDITIONS
Multiple associated conditions as noted above

DIAGNOSIS

HISTORY
• Successful treatment of FTT almost always is accomplished by a careful and detailed history because most cases are due to underfeeding or inappropriate feeding.
• Prenatal and developmental history
• Past medical history: acute/chronic disease affecting caloric intake, digestion, absorption, or causing increased energy need or defective utilization
• Medication history, including complementary and alternative medications
• Family history: stature of parents and growth trajectories of siblings, chronic diseases, genetic disorders, developmental delay
• Diet history from birth: breastfeeding or formula feeding; timing and introduction of solids;
who feeds the child, when, and how often; placement of child during feeds; amounts consumed/caloric intake; beverages consumed; snacking; vomiting or stooling associated with feeds; oral aversions or unusual behaviors during feeding

- Social history: family composition, socioeconomic status, hygiene practices, child-rearing beliefs, stressors, parental depression, parental substance abuse, caretaker personal history of abuse/neglect
- Review of systems: anorexia, activity level, mental status, fevers, dysphagia, vomiting, gastroesophageal reflux, stooling pattern/consistency, dysuria, urinary frequency

**PHYSICAL EXAM**

- A combination of anthropometric criteria, rather than one criterion, should be used, and measurements over time are required for diagnosis (1).
- Accurate measurement of height, weight, and head circumference on National Center for Health Statistics (NCHS) ([https://www.cdc.gov/growthcharts/](https://www.cdc.gov/growthcharts/)) growth charts may be more appropriate for breastfed infants ([http://www.who.int/childgrowth/standards/en/](http://www.who.int/childgrowth/standards/en/)).
- Growth charts exist for many other syndromes/conditions such as Down syndrome, Turner syndrome, and the premature infant.
- Exam should assess for the following:
  - Signs of dehydration or severe malnutrition are as follows:
    - Severity of malnutrition estimated via Gomez classification: Compare current weight for age with expected weight for age (50th percentile): severe, <60% of expected; moderate, 61–75%; mild, 76–90%.
  - Underlying medical disease
  - Dysmorphic features
  - Mental status (alert, responsive to stimuli)
  - Any signs of physical abuse and/or neglect
- Observe interaction with caregivers and feeding techniques, specifically bonding and social/psychological cues.

**DIFFERENTIAL DIAGNOSIS**

Differentiate based on growth patterns.

- FTT classically presents as low weight for age, with normal linear growth and head circumference or low weight for age, followed by decreased linear growth or low weight for age, leading to decreased linear growth and decreased head circumference (without neurologic signs).
  - In this situation, consider differential diagnosis as outlined in “Etiology and Pathophysiology.”
- If low linear growth with normal weight for length or low linear growth and proportionately low weight and decreased head circumference:
  - Consider genetic potential (constitutional short stature or growth delay), genetic syndromes, teratogens, and endocrine disorders.
- If microcephaly with prominent neurologic signs, with poor growth secondary to presumed neurologic disorder:
  - Consider TORCH infections, genetic syndromes, teratogens, and brain injury (i.e., hypoxic/ischemic).

**DIAGNOSTIC TESTS & INTERPRETATION**
Labs useful only in ~1% of cases and are generally not recommended (1,3)[C]
A period of addressing nutritional causes is preferable prior to extensive labs and other workup.

**Initial Tests (lab, imaging)**
Labs should be ordered based on history and physical exam findings and the age of the patient.
- Tests often considered in initial evaluation:
  - CBC, ESR
  - Electrolytes, BUN/creatinine, liver function tests
  - Urinalysis and urine culture
  - Lead level
- Other tests as dictated by the history and exam:
  - TSH, amylase/lipase, serum zinc level, iron studies, karyotype, genetic testing, sweat chloride test, stool for ova and parasite or fat/reducing substances, guaiac, α₁-antitrypsin and elastase, radioallergosorbent test for IgE food allergies, tissue transglutaminase and total IgA (celiac sprue), p-ANCA and anti–Saccharomyces cerevisiae antibodies (for inflammatory bowel disease [IBD]), TB test, HIV, hepatitis A and B, other infections

**Follow-Up Tests & Special Considerations**
- Prospective 3-day food diary for accurate record of caloric intake should be obtained.
- Home visit by a clinician to observe infant feeding, interaction of caretakers, and home environment (3,4)[B]
- Observe breastfeeding and/or formula preparation to ensure adequacy and offer instruction.
- Additional indicated evaluations may be performed by dietitians; occupational, physical, and speech therapists; social workers; developmental specialists; psychiatrists; psychologists; visiting nurses; lactation consultants; and/or child protection services.

**Diagnostic Procedures/Other**
Can consider
- Skeletal survey if suspicion of physical abuse
- Bone age if possible endocrine disorder
- Swallowing studies, small bowel follow-through if possible oromotor dysfunction, GERD, structural abnormalities
- Brain imaging if microcephalic and/or neurologic findings on examination
- Echocardiogram if murmur auscultated

---

**TREATMENT**

**GENERAL MEASURES**
- Treat underlying conditions.
- Caregiver and infant interaction should be evaluated in infants and children with FTT.
- Age-appropriate nutritional counseling should be provided (1)[C].
  - The goal is to improve nutrition to allow catch-up growth (weight gain 2 to 3 times > average for age).
- Calculate energy needs based on recommended energy intake for age and then increase by 50%.
Alternatively, may calculate caloric requirements for infants to achieve catch-up growth
  – kcal/kg/day required = RDA for age (kcal/kg) × ideal weight for height/actual weight,
    where ideal weight for height is the median weight for the patient’s height

Try various strategies to increase caloric intake, such as the following:
  – Optimize breastfeeding support; consider supplementation.
  – Higher calorie formulas
  – Addition of rice cereal or fats to current foods
  – Limit intake of milk to 24 to 32 oz/day.
  – Avoid juice and soda.
  – Vitamin and/or nutritional supplements
  – Assist with social and family problems (WIC, food stamps, and other transitional
    assistance).

Rapid high-calorie intake can cause diarrhea, malabsorption, hypokalemia, and
hypophosphatemia. Therefore, increasing formulas >24 kcal/oz is not recommended.

The target energy intake should be slowly increased to goal over 5 to 7 days.

Catch-up growth should be seen in 2 to 7 days.

Accelerated growth should be continued for 4 to 9 months to restore weight and height.

Consider Visiting Nurse Referral & Social Services evaluation to determine services family
may qualify for.

**MEDICATION**
Use only for identified underlying conditions.

**ISSUES FOR REFERRAL**
  – Refer as indicated for underlying conditions.
  – Multidisciplinary care is beneficial [1][A]. Specialized multidisciplinary clinics may be of
    benefit for children with complicated situations, failure to respond to initial treatment, or when
    the PCP does not have access to specialized services such as nutrition, psychology, PT/OT,
    and speech therapy.

**ADDITIONAL THERAPIES**
In severe cases, nasogastric tube feedings or gastrostomy may be considered.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
  – Most cases of FTT can be managed as outpatients.
  – Hospitalization should be considered if [1][C]:
    – Outpatient management fails.
    – There is evidence of severe dehydration or malnutrition.
    – There are signs of abuse or neglect.
    – There are concerns that the psychosocial situation presents harm to child.
    – During catch-up growth, some children will develop nutritional recovery syndrome:
      o Symptoms include sweating, increased body temperature, hepatomegaly (increased
        glycogen deposits), widening of cranial sutures (brain growth > bone growth), increased
        periods of sleep, fidgetiness, and mild hyperactivity.
    – There may also be an initial period of malabsorption with resultant diarrhea.
  – Catch-up growth should be seen in 2 to 7 days. If this is not seen, reevaluation of causes is
    needed.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- If specific disease is identified, follow up as indicated.
- Close (every 2–4 weeks at first, then 1–2 months if good progress), long-term follow-up with frequent visits is important to create and maintain a healthy, supportive environment (3,4)[B].
- Children with history of FTT are at increased risk of recurrent FTT, and long-term sequelae and growth should be monitored closely (1,4)[B].
- If the family fails to comply, child protection authorities must be notified.

Patient Monitoring
As noted above, long-term follow-up is important.

DIET
Nutritional requirements for a “normal” child:
- Infant
  - 120 kcal/kg/day, decreased to 95 kcal/kg/day at 6 months; if breastfed, ensure appropriate frequency and duration of feeding.
  - Between 6 and 12 months, continue breast milk and/or formula, but puréed foods should be consumed several times a day during this period.
- Toddler
  - Three meals plus two nutritional snacks, 16 to 32 oz of milk per day; avoid juice and soda and feed in a social environment.
  - Do not restrict fat and cholesterol in children <2 years.
- Rate of weight gain expected for age:
  - 0 to 3 months: 26 to 31 g/day
  - 3 to 6 months: 17 to 18 g/day
  - 6 to 9 months: 12 to 13 g/day
  - 9 to 12 months: 9 g/day
  - 1 to 3 years: 7 to 9 g/day

PATIENT EDUCATION
- Counsel parents regarding the need to avoid “food battles,” which worsen the problem.
- Educate parents regarding infant social and physiologic cues, formula/food preparation, proper feeding techniques, and importance of relaxed and social mealtimes.
- When environmental deprivation is identified, educating in a nonpunitive way is essential.
- WIC provides grants to states for supplemental foods, health care referrals, and nutrition education for low-income pregnant, breastfeeding, and nonbreastfeeding postpartum women and to infants and children up to age 5 years at nutritional risk: https://www.fns.usda.gov/wic/women-infants-and-children-wic

PROGNOSIS
- Many children with FTT show adequate improvement in dietary intake with intervention (2)[B].
- Some studies looking at children with FTT have demonstrated an association with later
problems with cognitive development, behavioral issues, and growth, but there is no consensus on these long-term outcomes or their clinical significance (1,4).

- Children with FTT are at increased risk for future undernutrition, overnutrition, and eating disorders.

**COMPLICATIONS**

May be related to underlying disorders.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- R62.51 Failure to thrive (child)
- P92.6 Failure to thrive in newborn

**CLINICAL PEARLS**

- FTT is a sign of inadequate nutrition. It is rarely due to a medical condition.
- Underlying medical and/or social issues are generally suggested by history and physical exam, and extensive laboratory or imaging tests are rarely needed.
- A multidisciplinary team approach to diagnosis and treatment is critical to help children with FTT and their families.
- Prompt diagnosis and intervention is important to decrease the risk of adverse effects.
FEMALE ATHLETE TRIAD
Miranda Gordon-Zigel, MD • Rahul Kapur, MD, CAQSM

BASICS

Syndrome of three interrelated clinical entities: low energy availability (EA) (with or without disordered eating [DE]), menstrual dysfunction (MD), and low bone mineral density (BMD) (1). There is also emerging research to suggest an expanded syndrome referred to as Relative Energy Deficiency in Sport (RED-S), which acknowledges that male athletes maybe at risk (2).

DESCRIPTION

- Female athlete triad was first described in 1992: Patients may meet criteria for only one or two parts of the triad.
- 2014 Female Athlete Triad Coalition consensus statement and the 2007 American College of Sports Medicine (ACSM) position stand suggest (1):
  - Each component of the triad represents a spectrum ranging from health to dysfunction.
  - EA is fundamental to the propagation of the triad.
  - Full recovery is not possible without correction of low EA.
- The International Olympic Committee’s updated position statement from 2014 now considers RED-S to be a more accurate representation of the psychological and physiologic stresses placed on the athlete’s body.
- Metabolic rate, menstrual function, bone health, immunity, protein synthesis, and cardiovascular and psychological health are all effected (2).
- Prevention and early intervention are essential to prevent progression to serious clinical end points of eating disorders, amenorrhea, and osteoporosis.
- RED-S also takes into account the effects of relative energy deficiency on male athletes, who are often affected in weight-sensitive sports (gymnastics, wrestling, cycling, etc.) (2).
- The changes in physiology should be viewed as a spectrum, with normal EA, BMD, and regular menses at one extreme and clinical eating disorders, osteoporosis, and amenorrhea at the other (2).

EA

- Dietary energy intake minus exercise energy expenditure; the core element of the triad
- Represents the amount of dietary energy remaining for bodily functions after correcting for exercise training
- EA (kcal/kg FFM/day) = [EI (kcal/day) − EEE (kcal/day)] where EEE is effective energy expenditure and FFM is fat free mass
- Low EA results in reduced capacity for cellular maintenance, thermoregulation, and growth.
- Low EA serves a causal role in the induction of exercise-associated menstrual disturbances.
- Low EA occurs either intentionally or inadvertently. Examples include increasing training disproportionately to energy intake; DE; and reducing energy intake by restricting, fasting, binging, and purging or use of diet pills, laxatives, diuretics, or enemas. Not all athletes meet diagnostic criteria from Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5) for eating disorders.

MD

- Low EA alters the hypothalamic-pituitary axis, resulting in functional hypothalamic
amenorrhea.

- MD ranges from eumenorrhea to amenorrhea.
- MD includes athletes who have low estrogen levels but still experience menstruation.
- Energy deficit results in MD at ~30 kcal/kg lean body mass per day.
- MD includes luteal suppression (shortened luteal phase, prolonged follicular phase, and decreased estradiol level), anovulation, oligomenorrhea (menstrual cycle >35 days), and primary and secondary hypothalamic amenorrhea.
- Primary amenorrhea (no menarche by age 15 years), although less common, can occur in young athletes. Secondary amenorrhea is defined as the absence of menstrual cycles for >3 months after menarche has been established.
- Although hypothalamic suppression is the most common cause of secondary amenorrhea in these athletes, other causes must be ruled out.

- BMD
  - Ranges from optimal bone health to osteoporosis
  - Peak BMD occurs at 19 years in females and 20.5 years in males.
  - Bone health encompasses bone strength as well as bone quality. The current practice standard (dual energy x-ray absorptiometry [DEXA]) measures bone density, not bone quality. This research may help providers better understand why two athletes with the same BMD may have very different bone fracture histories (3).
  - ACSM position stand recommends using the International Society for Clinical Densitometry (ISCD) guidelines for BMD Z-scores <−2.0 with a history of clinically significant fracture for diagnosis of osteoporosis.
  - Because most athletes have a higher BMD than nonathletes, ACSM recommends further workup for any athlete with a Z-score <−1, even in the absence of fracture.

- Endothelial dysfunction
  - Emerging evidence suggests that the female athlete triad is associated with endothelial dysfunction. Reduced levels of estrogen alter vasodilation. Athletic amenorrhea is associated with reduced brachial artery flow-mediated dilation, which has a 95% positive predictive value for coronary endothelial dysfunction. Consequences include decreased blood flow to muscles during exercise and accelerated atherosclerosis. In the future, this clinical syndrome may be considered a tetrad (4).

**EPIDEMIOLOGY**

**Prevalence**

- Overall prevalence: 0–16% of female athletes (5). Prevalence of two criteria varies: MD + BMD 0–8% (n = 460), MD + LE 18% (n = 80), and BMD + LE 4% (n = 80) (3).
- DE higher than general population (3)
- MD: Prevalence of secondary amenorrhea is as high as 60% in female athletes compared to 2–5% in the general population (3).
- Bone health: Using the World Health Organization (WHO) criteria for low BMD, prevalence of osteopenia (T-score between −1 and −2) ranges from 0% to 40% in female athletes, as compared to ~12% in the general population (3).

**ETIOLOGY AND PATHOPHYSIOLOGY**

- In functional hypothalamic amenorrhea, low EA disrupts the hypothalamic-pituitary-ovarian axis, decreasing pulsatile gonadotropin-releasing hormone (GnRH) release (5).
- Low GnRH levels decrease luteinizing hormone (LH) and follicle-stimulating hormone (FSH)
levels, decreasing estrogen production with resultant MD.

- Estrogen deficiency negatively affects bone density. A chronic state of malnutrition reduces the rate of bone formation and increases the rate of bone resorption. Changes in bone metabolism occur within 5 days of reductions in EA.

**RISK FACTORS**

- History of menstrual irregularities and amenorrhea; history of stress fractures and recurrent or nonhealing injuries; history of critical comments about eating or weight from parent or coach; history of depression; history of dieting; personality factors, including perfectionism and/or obsessiveness, overtraining, and inappropriate coaching behaviors (1)

- Lean physique, sports with an aesthetic component (ballet, figure skating, gymnastics, distance running, diving, and swimming), or sports with weight classifications (martial arts and wrestling). Frequent weigh-ins, consequences for weight gain, and win-at-all-cost attitude all increase risk (2).

- A lack of family or social support; intense training hours; social isolation, or entering a new environment (boarding school or college); an athlete with comorbid psychological conditions (anxiety, depression, and/or obsessive-compulsive disorder)

**GENERAL PREVENTION**

- Education of athletes (middle school through college), coaches, trainers, parents, and physicians. Young athletes are extremely impressionable and may turn negative comments and unhealthy advice into maladaptive eating and exercising habits.

- General screening during preparticipation exam (PPE) and annual physicals are endorsed by AAP, AAFP, ACSM, AOSSM, and AMSSM (6).

- Female Athlete Triad Coalition has 11-question screening to use during PPE (1).

- Screen athletes presenting with “red flag” conditions such as fractures, weight changes, fatigue, amenorrhea, bradycardia, orthostatic hypotension, syncope, arrhythmias, electrolyte abnormalities, or depression.

**COMMONLY ASSOCIATED CONDITIONS**

- Anorexia nervosa, bulimia nervosa, avoidant or restrictive food intake disorder, and other psychological disorders, including low self-esteem, depression, and anxiety (5)

- Low BMD predisposes athletes to stress fractures and may not be fully reversible. This may lead to a higher rate of fractures after menopause.

**DIAGNOSIS**

- The female athlete triad is a clinical diagnosis based primarily on patient history; screening for the female athlete triad at annual sports physicals or during routine exams and acute visits if there are concerns (1,5)[A]

- EDE-17 is the gold standard for eating disorder diagnosis.

**HISTORY**

Assess menstrual history (including hormonal contraceptive use), fracture history, and symptoms of depression. Assess dietary practices, eating behaviors, and history of weight changes. Dietary intake logs and a nutritional assessment by a sports dietitian can help. Assess body image, fear of weight gain, fluctuations in weight, history of DE, and use of laxatives, diet pills, or enemas.
PHYSICAL EXAM
- Height, weight, body mass index (BMI) <17.5% kg/m^2, <85% of expected body weight in adolescents, or ≥10% weight loss in 1 month (1)
- Common findings include bradycardia, orthostatic hypotension, hypothermia, cold or cyanotic extremities, lanugo, parotid gland enlargement or tenderness, epigastric tenderness, eroded tooth enamel, and knuckle or hand calluses (Russell sign).
- Patients with amenorrhea should undergo a pelvic exam to verify the presence of a uterus and evaluate for outflow tract abnormalities. Vaginal atrophy may be present if the patient is in a low estrogen state.

DIFFERENTIAL DIAGNOSIS
Screen for anorexia nervosa, bulimia nervosa, avoidant/restrictive food intake disorder, and rumination disorder using the DSM-5 criteria. Rule out the following in amenorrheic patients:
- Pregnancy
- Endocrine abnormalities: thyroid dysfunction, Cushing syndrome
- Hypothalamic dysfunction: psychological stress-induced amenorrhea, medication-induced amenorrhea, Kallmann syndrome
- Pituitary dysfunction: prolactinoma, Sheehan syndrome, sarcoidosis, empty sella syndrome
- Ovarian dysfunction: polycystic ovarian syndrome, premature ovarian failure, menopause, gonadal dysgenesis, Turner syndrome, ovarian neoplasm, autoimmune disease
- Uterine dysfunction: Asherman syndrome, absence of uterus

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Basic metabolic panel, magnesium, phosphorus, albumin, CBC with differential, ESR, thyroid-stimulating hormone (TSH), calcium, 25-OH vitamin D, and urinalysis (1,5)
- Evaluation for secondary amenorrhea includes urine hCG and serum FSH, LH, prolactin, and TSH.
- Pelvic ultrasound in patients with hyperandrogenism to exclude polycystic ovaries or virilizing ovarian tumors
- ECG to rule out prolonged QT interval

Follow-Up Tests & Special Considerations
- BMD testing by DEXA is based on a risk stratification model (1). Risk factors include DE, eating disorders >6 months, hypoestrogenism, amenorrhea, oligomenorrhea, and/or in patients with a history of stress fractures or fractures from minimal impact.
- If components of the triad persist, ISCD 2013 guidelines suggest reevaluation by the same DEXA machine every 1 to 2 years.

TREATMENT
- The goal is to optimize nutritional status and treat maladaptive behavioral disorders (1,3)[A].
- A multidisciplinary team including a physician, registered dietitian, and behavioral health provider. Build open lines of communication with coaches, trainers, and family.
- A positive EA of >30 kcal/kg of fat-free muscle mass per day is sufficient to restore menses (5)[A].
Physically active females should strive for an EA of >45 kcal/kg of fat-free muscle mass per day (1)[A].

MEDICATION
First Line
- Increasing EA through appropriate nutrition is the best strategy for normalizing gonadotropin pulsatility and release. The use of combination oral contraceptive pills (cOCPs), hormone replacement therapy (HRT), and/or bisphosphonates has not been clearly shown to increase BMD or aid in the restoration of normal menstrual cycling. Transdermal estradiol with cyclic oral progesterone can be considered in patients with particularly low BMD Z-scores and fracture histories who do not respond to 1 year of nonpharmacologic management.
- Transdermal estradiol can also be given to minimize further bone loss in patients >16 years and <21 years who, despite adequate nutrition and body weight gain, continue to have decreasing BMD and functional hypothalamic amenorrhea.
- cOCPs do have potential to mask signs of RED-S and do not correct underlying energy deficiency. They can also suppress androgen release, potentially causing a decrease in BMD (2).

- Provide calcium (1,500 mg/day) and vitamin D supplementation to maintain serum levels within 32 to 50 mg/mL (1)[A].

- In male athletes, with RED-S, testosterone replacement therapy can be helpful in patients with hypogonadism and osteoporosis (2).

Ongoing Care

Patients should have regular follow-up with a multidisciplinary treatment team (6)[A].

- Cognitive-behavioral therapy (CBT) is effective for exercising women with DE and may be more beneficial than nutritional counseling alone in women with DE behavior.

- “Clearance and Return to Play (RTP) Guidelines by Medical Risk Stratification” helps determine when to allow an athlete to return to competition. More research is needed to validate this model (1)[A].

- To continue training and competing, athletes with eating disorders must agree to the following stipulations as part of a behavioral contract: to comply with all treatment strategies; to be closely monitored by health care providers; to place treatment goals over training goals; and to modify the type, duration, and intensity of training or competition as necessary.

- The RED-S Risk Assessment Model can be used to aid decision to clear athletes to return to play (2).

PATIENT EDUCATION

All young female patients should be counseled on the importance of proper nutrition, calcium and vitamin D intake, and the benefits of regular weight-bearing exercise. Patients presenting with ≥1 components of the triad should be educated about the short- and long-term effects of
low BMD (1,3)[A].

- RED-S effects on performance: decrease endurance, increased injury risk, decreased training response, impaired judgment, decreased coordination, decreased concentration, irritability, depression, decreased glycogen stores, decreased muscle strength (2)

**PROGNOSIS**

- The short- and long-term prognosis for patients with female athlete triad depends on time to diagnosis and response to treatment.
- It is estimated that amenorrheic women will lose 2–3% of bone mass per year without intervention.
- With early diagnosis and treatment using a multidisciplinary team, the prognosis for patients with the female athlete triad is good. Patients regain normal menstrual cycling and increase BMD.
- Because the triad often occurs within the age window of optimal bone strengthening, patients with a prolonged disease course may suffer from complications of decreased BMD throughout their adolescent and adult life.
- Patients with DE behaviors often require long-term therapy to manage their disease.

Algorithms: Amenorrhea, Primary (Absence of Menarche by Age 16 Years); Amenorrhea, Secondary; Weight Loss, Unintentional
CODES
ICD10
- F50.9 Eating disorder, unspecified
- N91.2 Amenorrhea, unspecified
- R53.83 Other fatigue

CLINICAL PEARLS
- The female athlete triad consists of low EA (with or without DE), MD, and low BMD. Athletes may exhibit varying degrees of dysfunction in any of these three areas. There is emerging research regarding an expanded syndrome called RED-S.
- Screen at-risk women and men to allow for early diagnosis and intervention.
- Early intervention by a multidisciplinary team, including physicians, registered dietitians, mental health professionals, coaches, trainers, and parents, is the most successful strategy to minimize further bone loss, recover BMD, and regain normal menstrual function.
- Current guidelines recommend screening for abnormal BMD using DEXA studies for patients with DE, eating disorders >6 months, hypoestrogenism, amenorrhea, oligomenorrhea, and/or in patients with a history of stress fractures or fractures from minimal impact.
FEVER OF UNKNOWN ORIGIN (FUO)
Scott T. Henderson, MD

BASICS

DESCRIPTION
- Classic definition
  - Repeated fever >38.3°C
  - Fever duration at least 3 weeks
  - Diagnosis remains uncertain after 1 week of study in the hospital.
- The definition of fever of unknown origin (FUO) has evolved and is based on patient characteristics and presentation. The need for in-hospital evaluation has been eliminated in previously healthy people.
- Some expand the definition to include nosocomial, neutropenic (immunodeficient), and HIV-associated fevers.

EPIDEMIOLOGY

Incidence
The exact incidence is not known

ETIOLOGY AND PATHOPHYSIOLOGY
- >200 causes; each with prevalence of ≤5%
- Most commonly, FUO is an atypical presentation of a common condition.
- Spectrum of causes varies widely.
  - Noninfectious inflammatory diseases are the most frequent causes in high-income countries.
    - Common causes include temporal arteritis, polymyalgia rheumatica, or rheumatoid arthritis.
- Infection
  - Abdominal or pelvic abscesses
  - Amebic hepatitis
  - Catheter infections
  - Cytomegalovirus
  - Dental abscesses
  - Endocarditis/pericarditis
  - HIV (advanced stage)
  - Mycobacterial infection (often with advanced HIV)
  - Osteomyelitis
  - Pyelonephritis or renal abscess
  - Sinusitis
  - Wound infections
  - Other miscellaneous infections
- Neoplasms
  - Atrial myxoma
  - Colorectal cancer and other GI malignancies
  - Hepatoma
  - Lymphoma
- Leukemia
- Solid tumors (renal cell carcinoma)

- **Noninfectious inflammatory disease**
  - Connective tissue diseases
    - Adult Still disease
    - Rheumatoid arthritis
    - Systemic lupus erythematosus
  - Granulomatous disease
    - Crohn disease
    - Sarcoidosis
  - Vasculitis syndromes
    - Giant cell arteritis
    - Polymyalgia rheumatica

- **Other causes**
  - Alcoholic hepatitis
  - Cerebrovascular accident
  - Cirrhosis
  - Medications
    - Allopurinol, captopril, carbamazepine, cephalosporins, cimetidine, clofibrate, erythromycin, heparin, hydralazine, hydrochlorothiazide, isoniazid, meperidine, methyldopa, nifedipine, nitrofurantoin, penicillin, phenytoin, procainamide, quinidine, sulfonamides
  - Endocrine disease
  - Factitious/fraudulent fever
  - Occupational causes
  - Periodic fever
  - Pulmonary emboli/deep vein thrombosis
  - Thermoregulatory disorders

In up to 20–30% of cases, the cause of the fever is never identified despite a thorough workup.

**RISK FACTORS**

- Recent travel (malaria, enteric fevers)
- Exposure to biologic or chemical agents
- HIV infection (particularly in acute infection and advanced stages)
- Elderly
- Drug abuse
- Immigrants
- Young, (typically) female health care workers (factitious fever)

**Geriatric Considerations**
Common infectious causes of FUO in geriatric populations include intra-abdominal abscess, urinary tract infection, tuberculosis (TB), and endocarditis. Other common causes of FUO in patients >65 years include malignancies (particularly hematologic cancers) and drug-induced fever.

**Pediatric Considerations**

~50% of FUO in pediatric cases are infectious. Collagen vascular disease and malignancy are
Inflammatory bowel disease is a common cause of FUO in older children and adolescents.

**DIAGNOSIS**

**HISTORY**
- Onset and pattern of fever
- Constitutional symptoms:
  - Chills, night sweats, myalgias, weight loss with an intact appetite (infectious etiology)
  - Arthralgias, myalgias, fatigue (inflammatory etiology)
  - Fatigue, night sweats, weight loss with loss of appetite (neoplastic etiology)
- Past medical history: chronic infections, abdominal diseases, transfusion history, malignancy, psychiatric illness, and recent hospitalization
- Past surgical history: type of surgery performed, postoperative complications, and any indwelling foreign material
- Comprehensive medication history, including over-the-counter and herbal products
- Family history, such as periodic fever syndromes and recent febrile illnesses in close contacts
- Social history: travel, exposures, living environment, sexual activity, recreational drug use

**ALERT**
Obtain a thorough travel, psychosocial, occupational, sexual, medication and recreational drug use history.

**PHYSICAL EXAM**
Physical findings with high diagnostic yield generally involve skin, eyes, lymph nodes, liver, and spleen. Helpful clues can be found with:
- Funduscopic exam for choroid tubercles or Roth spots
- Temporal artery tenderness
- Oral-mucosal lesions
- Cardiac auscultation for bruits and murmurs
- Pulmonary exam: consolidation or effusion
- Abdominal palpation for organomegaly and tenderness or peritoneal signs
- Rectal examination for blood, fluctuance, and/or tenderness
- Testicular examination
- Lymph node examination
- Skin and nail bed exam for clubbing, nodules, lesions, and erosions
- Focal neurologic signs
- Musculoskeletal exam for tenderness or effusion
- Serial exams help identify evolving physical signs (e.g., findings associated with endocarditis).

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- CBC, C-reactive protein, ESR
- Peripheral blood smear
- Electrolytes, BUN, and creatinine; LFT; calcium
- Lactate dehydrogenase
Follow-Up Tests & Special Considerations

- HIV testing
- Blood cultures (not to exceed six sets)
- Urinalysis and urine culture
- Chest x-ray
- CT or MRI of abdomen and pelvis (with directed biopsy, if indicated) (1)[C]

- Rheumatoid factor and antinuclear antibody test
- Serologies: Epstein-Barr, hepatitis, syphilis, Lyme disease, Q fever, cytomegalovirus, brucellosis, amebiasis, coccidioidomycosis
- Serum ferritin
- Serum procalcitonin
- Serum protein electrophoresis
- AFB smear
- Sputum and urine cultures for TB
- TB testing
  - Tuberculin skin test
    - May not be helpful if anergic or acute infection
    - If test negative, repeat in 2 weeks.
  - Interferon gamma release assay (IGRA)
    - Preferred in those likely to be infected with TB and/or who are BCG-vaccinated
- Thyroid function tests
- Technetium-based scan (infection tumor) (1)[B]
- FDG-PET/CT scan if infectious process, inflammatory process, or tumor suspected; PET scans have a high negative predictive value and good sensitivity (but may have false positives) (2)[A].
- Ultrasound of abdomen and pelvis (with directed biopsy, if indicated) if renal obstruction or biliary pathology suspected
- Echocardiogram if endocarditis, atrial myxomas, or pericardial effusion is suspected
- Lower extremity Doppler if deep vein thrombosis/pulmonary embolism suspected
- CT scan of chest if pulmonary embolism suspected
- Indium-labeled leukocyte scanning if inflammatory process or occult abscess suspected
- Bone scan if osteomyelitis or metastatic disease suspected

Diagnostic Procedures/Other

- Liver biopsy if granulomatous disease suspected (1)[C]
- Temporal artery biopsy, particularly in the elderly
- Lymph node, muscle, or skin biopsy, if clinically indicated
- Bone marrow aspiration biopsy with smear, culture, histologic examination, and flow cytometry
- Lumbar puncture, if clinically indicated

TREATMENT

GENERAL MEASURES

- Treatment depends on the specific etiology.
Therapeutic trials are a last resort and should be as specific as possible based on available clinical evidence. Avoid “shotgun” approaches because they obscure the clinical picture, have untoward effects, and do not provide a diagnostic solution (1)[C].

MEDICATION
First Line
- First-line drugs depend on the diagnosis.
- Evidence does not support isolated treatment of fever (3)[C].

Second Line
Consider a therapeutic trial only if the patient has localizing symptoms associated with the fever or continues to decline. Consultation with appropriate specialists (infectious disease, rheumatology) is recommended in this case.
- Antibiotic trial based on patient’s history and suspected culture negative endocarditis
- Antituberculous therapy if there is a high risk for TB pending definitive culture results
- Corticosteroid trial based on patient’s history (once occult malignancy is ruled out) if temporal arteritis is suspected

ALERT
If a steroid trial is initiated, patient may have a relapse after treatment or if certain conditions (e.g., TB) have been undiagnosed.

ADDITIONAL THERAPIES
Febrile patients have increased caloric and fluid demands.

SURGERY/OTHER PROCEDURES
The need for exploratory laparotomy has been largely eliminated with the advent of more sophisticated tests and imaging modalities.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Reserved for the ill and debilitated
- Consider if factitious fever has been ruled out or an invasive procedure is indicated.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
If the etiology of the fever remains unknown, repeat the history, physical exam, and screening lab studies.

DIET
No specific dietary recommendations have been shown to ameliorate undiagnosed fever.

PATIENT EDUCATION
Maintain an open line of communication between physician and patient/family as the workup progresses:
- The extended time required in establishing a diagnosis can be frustrating.
PROGNOSIS

- Depends on etiology and age
  - Patients with HIV have the highest mortality.
- Prognosis worse if delay in diagnosis
- Spontaneous remission is not uncommon in patients with unknown cause of FUO after a through workup including a negative FDG-PET/CT scan
- 1-year survival rates (reflecting deaths due to all causes)

COMPLICATIONS

Depends on etiology

Pregnancy Considerations

Fever increases the risk of neural tube defects in pregnancy and can also trigger preterm labor.

CODES
ICD10
R50.9 Fever, unspecified

CLINICAL PEARLS

- A sequential approach to FUO based on a careful history, physical examination, with targeted testing and imaging typically yields an appropriate diagnosis and avoids excessive nontargeted testing.
- Empiric therapy is indicated only for carefully defined circumstances.
- FUO cases that defy precise diagnosis after intensive investigation and prolonged observation generally have a favorable prognosis.
- FUO in older persons may represent an atypical presentation of a common disease.
- The most common causes of FUO in high-income countries are noninfectious inflammatory diseases and idiopathic causes.
FIBROCYSTIC CHANGES OF THE BREAST
Sharon L. Koehler, DO, FACS

BASICS

DESCRIPTION
- Fibrocystic changes (FCC) are not a disease but refers to a constellation of benign, nonproliferative histologic findings. It is the most frequent female benign clinical breast finding.
- FCC are seen clinically in up to 50% and histologically in up to 90% of women (1).
- FCC may also be described as aberrations of normal development and evolution.
- The most common symptoms are cyclic pain, tenderness, swelling, and fullness.
- The breast tissue may feel dense with areas of thicker tissue having an irregular, nodular, or ridge-like surface.
- Women may experience sensitivity to touch with a burning sensation. For some, the pain is so severe that it limits exercise or the ability to lie prone. Usually affects both breasts, most often in the upper outer quadrant where most of the milk-producing glands are located.
- Histologically, in addition to macrocysts and microcysts, FCC may contain solid elements including adenosis, sclerosis, apocrine metaplasia, stromal fibrosis, and epithelial metaplasia and hyperplasia.
  - Depending on the presence of epithelial hyperplasia, FCC is classified as nonproliferative, proliferative without atypia, or proliferative with atypia (2).
  - Nonproliferative lesions are generally not associated with an increased risk of breast cancer.
- System(s) affected: endocrine/metabolic, reproductive
- Synonym(s): diffuse cystic mastopathy; fibrocystic disease; chronic cystic mastitis; mammary dysplasia

EPIDEMIOLOGY
FCC occurs with great frequency in the general population. It affects women between the ages of 25 and 50 years, and it is rare below the age of 20 years.

Incidence
Unknown but very frequent

Prevalence
Up to 1/3 of women age 30 to 50 years have cysts in their breasts (2). It most commonly presents in the 3rd decade, peaks in the 4th decade when hormonal function is at its peak, and sharply diminishes after menopause.
- With hormone replacement therapy, FCC may extend into menopause.
- Less common in East Asian races

ETIOLOGY AND PATHOPHYSIOLOGY
- FCC originates from an exaggerated response of breast stroma and epithelium to a variety of circulating and locally produced hormones (mainly estrogen and progesterone) and growth factors.
- Cysts may form due to dilatation of the lobular acini possibly due to imbalance of fluid
secretion and resorption or due to obstruction of the duct leading to the lobule.

**RISK FACTORS**
- In many women, methylxanthine-containing substances (e.g., coffee, tea, cola, chocolate) can potentiate symptoms of FCC, although a direct causality has not been established.
- Diet high in saturated fats may increase risk of FCC.

**COMMONLY ASSOCIATED CONDITIONS**
FCC categorized as proliferative with atypia confers a higher risk of breast cancer.

**DIAGNOSIS**

**HISTORY**
- Obtain personal history of breast biopsy and family history of breast disease (benign or malignant). It is important to ascertain if the patient has a known family history of BRCA1- or BRCA2-related cancer.
- Inquire regarding pertinent signs/symptoms, such as breast pain, engorgement, nipple discharge, palpable lumps, and tenderness.
  - Symptomatically, the condition is manifested as premenstrual cyclic mastalgia, with pain and tenderness to touch.

**PHYSICAL EXAM**
- The patient should be examined in the following positions while disrobed down to the waist:
  - With the patient standing with arms at sides, observe for elevation of the level of a nipple, dimpling, bulging, and peau d’orange.
  - With the patient’s arms raised above her head, observe for dimpling and elevation/retraction of the nipple (may accentuate a mass fixed to the pectoral fascia). If so, have the patient push her hands down against her hips to flex and tense the pectoralis major muscles; move the mass to determine fixation to the underlying fascia.
  - If the patient has large and pendulous breasts, ask her to lean forward, so that her breasts hang free from the chest wall (retraction and masses may become more evident).
  - Axillary lymph nodes are evaluated with the patient sitting up, the arm supported by the examiner’s arm while finger pads gently palpate the axilla from the posterior axillary line to the pectoralis.
  - With the patient lying supine, palpate with the pads of the three middle fingers (with varying pressures from light, to medium, to deep), rotating the fingers in small circular motions and moving in vertical overlapping passes from rostral to caudal and then back to caudal to rostral in the next pass. The lateral half of the breast is best palpated with the patient rolled onto the contralateral hip and the medial half with the patient supine, both with the ipsilateral hand behind the head. The entire breast from the 2nd to 6th rib and from the left sternal border to the midaxillary line must be palpated against the chest wall.
- Be certain to examine the creases under and between the breasts. If the patient has noted a lump, ask her to point it out; always palpate the opposite breast first.
- Patients with FCC have clinical breast findings that range from mild alterations in texture to dense, firm breast tissue with palpable masses.

**DIFFERENTIAL DIAGNOSIS**
- Pain
  - Mastitis
  - Costochondritis
  - Pectoralis muscle strain
  - Neuralgia
  - Breast cancer
  - Angina pectoris
  - Gastroesophageal reflux (GERD)
  - Superficial phlebitis of the thoracoepigastric vein (Mondor disease)
- Masses
  - Breast cancer
  - Sebaceous cyst
  - Fibroadenoma
  - Lipoma
  - Fat necrosis
  - Phyllodes tumor
  - Granuloma
- Skin changes
  - Breast cancer (peau d’orange: thickened skin similar to peel of an orange)
  - Eczema
  - Infection
  - Fungus
  - Paget disease

**DIAGNOSTIC TESTS & INTERPRETATION**
- Evaluation should focus on excluding breast cancer.
- Testing may be conducted based on a level of clinical suspicion.
- FCC can be evaluated with mammogram, although dense breast tissue may appear normal in women <35 years of age.
- Ultrasound (US) is the most important method in assessing a cyst.

**Initial Tests (lab, imaging)**
- On mammogram, FCC appears as nodular densities of breast tissue; solitary cysts can appear as round or ovoid or well-circumscribed masses, usually with low to intermediate density. FCC may also contain calcifications.
- On US, if a simple cyst is demonstrated as an anechoic structure with imperceptible wall and posterior acoustic enhancement, benign diagnosis is confirmed and no further imaging or intervention is indicated. However, if the cyst appears to be thick-walled and/or contains internal echoes, differential diagnosis should include a complicated cyst, an abscess, a galactocele, or a focal duct ectasia in the appropriate clinical contexts.
- MRI is indicated in patients with BRCA1 or BRCA2 mutation or in any woman with ≥25% lifetime risk for breast cancer. Additionally, MRI may be indicated for extremely dense breasts as well as inconclusive findings on other breast imaging.
- On MRI, cystic changes are well-circumscribed lesions of high-signal intensity on T2-weighted sequences and of low-signal intensity on T1-weighted images (2).

**Diagnostic Procedures/Other**
Fine-needle aspiration (FNA) biopsy:
- Allows differentiation of cystic and solid lesions
- Aspirate may be straw-colored, dark brown, or green.
- Cells sent for cytology can reveal cancer with high accuracy.
- Low morbidity

If mass disappears, no further evaluation necessary (including cytologic evaluation of aspirated fluid).

On the basis of the presence and degree of epithelial hyperplasia, FCC is comprised of nonproliferative (approximately 65% of the total), proliferative without atypia (approximately 30% of the total), and proliferative with atypia (approximately 5–8% of the total) (3).

**Test Interpretation**

Certain histologic changes in the setting of FCC confer an increased risk for breast cancer:
- Nonproliferative changes: relative risk of 1.2 to 1.4
- Proliferative disease (PD) without atypia: relative risk of 1.7 to 2.1
- PD with atypia: relative risk ≥4 (4)

**TREATMENT**

After ruling out malignancy by means of examination and/or imaging and diagnostic procedures, FCC may not require treatment and often resolves with time.

Cool compresses, avoiding trauma, and around-the-clock wearing of a well-fitting, supportive brassiere may be useful for symptom relief.

Reduction in caffeine, additional supplementation with vitamin E, and/or evening primrose oil have been advocated. Recent trials have not proven benefit (2).

**MEDICATION**

**First Line**

Analgesics and anti-inflammatory drugs are used to reduce cyclic breast pain and swelling. This includes oral and topical NSAIDs or acetaminophen.

- Acetaminophen: 1,000 mg every 6–8 hours; maximum daily dose of 3,000 mg unless directed by health care provider
- Ibuprofen: 400 mg every 4 to 6 hours as needed
- Naproxen: 500 mg every 12 hours as needed

**Second Line**

Oral contraceptives (OCPs) may be useful in modulating symptoms or in preventing the development of new changes in females with cyclic symptoms.

For severe pain, consider the following (5,6)[B]:
- Danazol is effective for reducing breast pain and tenderness but has androgenic effects and is associated with hepatotoxicity and teratogenicity, which limits its use. This drug is administered orally at a dosage of 100 to 400 mg/day in 2 divided doses.
- Tamoxifen 10 mg/day for 3 to 6 months. Along with teratogenicity, this selective estrogen receptor modulator (SERM) can increase the risk of thromboembolism and endometrial carcinoma in treated females.
- Several other medications, such as bromocriptine and GnRH agonists have been studied but are associated with toxicities.
ISSUES FOR REFERRAL
- If discrete palpable lesion in a woman <35 years: US, then refer to a surgeon
- If discrete palpable lesion in a woman >35 years: diagnostic mammography ± US, then refer to surgeon

SURGERY/OTHER PROCEDURES
- Breast cyst aspiration can be both diagnostic and therapeutic.
- Core-needle biopsies performed under stereotactic guidance with vacuum assistance has similar accuracy in distinguishing between malignant and benign lesions compared to open surgical biopsy (7)[A].
- Biopsy results must be assessed for concordance.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- The use of vitamin E has shown effectiveness in treating breast pain due to FCC (4)[B].
- Little evidence supports the use of evening primrose oil for FCC.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Condition is benign, chronic, and recurrent.

Patient Monitoring
- Follow-up times are variable, depending on the clinical situation and pertinent family history.
- US is useful to differentiate cysts from solid lesions and in evaluating women <35 years of age for FCC but is not useful for screening.
- Screening mammograms: Refer to the USPSTF, ACOG, or ACS recommendations for screening schedules.

DIET
The role of caffeine consumption in the development and treatment of FCC has never been proven; however, some patients report relief of symptoms after abstinence from coffee, tea, and chocolate.

PATIENT EDUCATION
- Patient information on fibrocystic breasts from the Mayo Foundation for Medical Education and Research: www.mayoclinic.com/health/fibrocystic-breasts/DS01070
- Information on breast cancer prevention from the National Cancer Institute: www.cancer.gov
- Information on fibrocystic breasts from the American Cancer Society: www.cancer.org/Healthy/FindCancerEarly/WomensHealth/Non-CancerousBreastConditions/non-cancerous-breast-conditions-fibrocystic-changes

REFERENCES

ADDITIONAL READING

CODES
ICD10
- N60.19 Diffuse cystic mastopathy of unspecified breast
- N60.09 Solitary cyst of unspecified breast
- N60.29 Fibroadenosis of unspecified breast

CLINICAL PEARLS
- FCC of the breast comprise a spectrum of histopathologic changes that are a common finding
in reproductive-age women. The former term of fibrocystic disease is a misnomer.

- Atypia, as demonstrated histopathologically, confers an increased cancer risk.
- NSAIDs are the first-line treatment.
- OCPs, danazol, and tamoxifen are second-line treatments, with considerable adverse effects.
- Consultation with a breast specialist is recommended for symptomatic disease refractory to simple measures, or for diagnostic issues.
FIBROMYALGIA
F. Stuart Leeds, MD, MS

BASICS

DESCRIPTION
- Chronic, widespread noninflammatory musculoskeletal pain syndrome with multisystem manifestations. Although the specific pathophysiology has not been fully elucidated, it is generally thought to be a disorder of altered central pain regulation.
- Synonym(s): FMS; fibrositis, fibromyositis (misnomers); "psychogenic rheumatism" (archaic and inaccurate)

EPIDEMIOLOGY

Incidence
- Predominant sex: female (70–90%) > male (1)
- Predominant age range: 20 to 65 years

Prevalence
2–5% of adult U.S. population (2); 8% of primary care patients

ETIOLOGY AND PATHOPHYSIOLOGY

- Idiopathic; appears to be a primary disorder of central pain processing (central sensitization) with afferent augmentation of peripheral nociceptive stimuli
- Alterations in neuroendocrine, neuromodulation, neurotransmitter, neurotransporter, biochemical, and neuroreceptor function/physiology
- Sleep abnormalities—α-wave intrusion
- Inflammation is not a feature of fibromyalgia.

Genetics
- Genetics
  - High familial aggregation
  - Inheritance is unknown but likely polygenic.
  - Odds ratio may be as high as 8.5 for a first-degree relative of a familial proband.
- Environmental—several triggers have been described:
  - Physical trauma or severe illness
  - Stressors (e.g., work, family, life events, and physical or sexual abuse)
  - Viral and bacterial infections

RISK FACTORS
- Female gender
- Poor functional status
- Negative/stressful life events
- Low socioeconomic status

GENERAL PREVENTION
No known strategies for prevention
COMMONLY ASSOCIATED CONDITIONS

- Often a comorbid condition with other rheumatologic or neurologic disorders
- Obesity is common and associated with increased severity of symptoms.

DIAGNOSIS

- Original 1990 American College of Radiology (ACR) criteria, still widely used: (i) pain in all four quadrants > 3 months, (ii) axial (neck/spine) involvement, (iii) tender points ≥11
- 2010–11 ACR criteria, revised in 2016
  - Based on Widespread Pain Index (WPI) and Symptom Score (SS)
  - Generalized pain present in 4/5 body regions, and
  - Must have WPI ≥7 + SS ≥5, or WPI 4–6 and SS ≥9, and
  - Symptoms for >3 months
  - Fibromyalgia may be diagnosed irrespective of other active disease entities (i.e., it need not be the only explanation for the patient’s symptoms)
- WPI/SS patient scoring and diagnosis tool: https://neuro.memorialhermann.org/uploadedFiles/_Library_Files/MNII/NewFibroCriteriaSurv
- The Visual Analogue Scale Fibromyalgia Impact Questionnaire (VASFIQ) is recommended for initial and serial assessment of patient’s functional status: http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3383533/figure/fig1-1759720X11416863/.

HISTORY

- Invariant symptoms include
  - Chronic widespread pain ≥3 months: bilateral limbs and in the axial skeleton
  - Fatigue and sleep disturbances
- Often present:
  - Mood disorders, including depression, anxiety, and panic symptoms
  - Cognitive impairment: qualitatively different from that seen in isolated mood disorders (“fibro fog”)
  - Headaches: typically, tension and migraine types
  - Other regional pain syndromes, such as irritable bowel syndrome, chronic pelvic pain, vulvodynia, and interstitial cystitis
  - Paresthesias, often “nonanatomic”
  - Exercise intolerance, dyspnea, and palpitations
  - Sexual dysfunction
  - Ocular dryness
  - “Multiple chemical sensitivity” and an increased tendency to report drug reactions
  - Impaired social/occupational functioning
  - Symptoms can wax and wane on a day-to-day basis, varying in quality, intensity, and location.

PHYSICAL EXAM

- Classic fibromyalgia trigger points (TPs): 9 symmetric pairs (5 anterior, 4 posterior).
- The presence of ≥11 TPs carries a sensitivity of 88% and specificity 81% for the disease
- TPs in fibromyalgia are distinct from the “trigger points” found in myofascial pain syndromes and are not sites for therapeutic injection
Examine joints for swelling, tenderness, erythema, decreased range of motion, crepitus, and cystic or mass lesions. These are typically absent in fibromyalgia.

Document absence of inflammatory features (e.g., no synovitis, enthesopathy, dermatologic, or ocular findings)

Neurologic exam: may demonstrate generalized or “nonanatomic” dysesthesia, hyper- or hypoesthesia

**DIFFERENTIAL DIAGNOSIS**

- Rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), sarcoidosis, and other inflammatory connective tissue disorders
- Diffuse/advanced osteoarthritis (OA)
- Seronegative spondyloarthropathies (AS, psoriatic arthritis, etc.)
- Polymyalgia rheumatica
- Inherited myopathies
- Drug-induced and endocrine myopathies
- Viral/postviral polyarthralgia
- Anemia and iron deficiency
- Electrolyte disturbances: Mg, Na, K, Ca
- Obstructive sleep apnea
- Restless leg syndrome
- Osteomalacia/vitamin D deficiency
- Opioid-induced hyperalgesia
- Hypothyroidism
- Multiple sclerosis
- Lyme disease
- Hepatitis B and C (chronic)
- Inclusion-body myositis
- Spinal stenosis/neuropathies
- Generalized muscular deconditioning
- Peripheral vascular disease
- Somatoform disorder
- Overlap syndromes
  - Chronic fatigue syndrome/chronic fatigue immune dysfunction syndrome (CFIDS)
  - Myofascial pain syndrome (more anatomically localized than fibromyalgia, but they may co-occur)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- CBC with differential, erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP), CPK, thyroid-stimulating hormone (TSH), comprehensive metabolic profile; consider 25-OH vitamin D, Mg, vitamin B₁₂, folate, and urine drug screen.
- Antinuclear antibody (ANA), rheumatoid factor (RF), and other rheumatologic labs generally unnecessary, unless there is evidence of an inflammatory connective tissue disorder
- Imaging is not indicated, except to exclude other specific diagnoses.

**Diagnostic Procedures/Other**

- Sleep studies may be indicated to rule out obstructive sleep apnea or narcolepsy.
Consider psychiatric or neuropsychiatric evaluation for mood disorders and cognitive disturbances.

**TREATMENT**

Evidence-based interventions:

- Include both medication and nonpharmacologic interventions. In general, a partial or complete remission can only be achieved with committed changes in lifestyle, including regular exercise, proper sleep hygiene, and smoking cessation.

- Nonpharmacologic
  - Educate about diagnosis, signs, symptoms, and treatment options: Online resources include:
    - [www.fmaware.org](http://www.fmaware.org)
    - [http://www.fibromyalgiaforums.org/](http://www.fibromyalgiaforums.org/)
  - VASFIQ for initial assessment and interval evaluation during treatment
  - Cognitive-behavioral therapy (CBT) improves mood, energy, pain, and functional status
  - Acceptance and Commitment Therapy (ACT)
  - Aerobic exercise: moderately intense, with gradual titration to minimize symptom exacerbation (“start low and slow”)
  - Strength/resistance training—mild to moderate
  - Tai chi—equal or superior to aerobic exercise (3)[B]
    - Aquatic exercise training
    - Mixed exercise training (combined aerobic, resistance, flexibility)
    - Weight loss may augment the benefits of exercise
    - Sleep hygiene
    - Mitigate/eliminate tobacco, alcohol, and substance use

- Pharmacologic
  - Three FDA-approved drugs: duloxetine, milnacipran, and pregabalin; others are off-label.
    - Recent studies suggest that these agents, when used as monotherapy, only benefit a minority of responders.
    - **Caution:** Fibromyalgia patients are frequently treated with multidrug regimens; monitor closely for drug interactions, sedative, serotonergic, and anticholinergic effects.

**MEDICATION**

**First Line**

- Amitriptyline 10 to 50 mg PO at bedtime to treat pain, fatigue, and sleep disturbances (4)[A]. Other TCAs (imipramine, desipramine, nortriptyline) may be similarly effective.
- Duloxetine initially 30 mg/day for 1 week and then increase to 60 mg/day as tolerated. Taper if discontinued (4)[A].
- Milnacipran day 1: 12.5 mg/day; days 2 to 3, begin dividing doses: 12.5 mg BID; days 4 to 7: 25 mg BID; after day 7: 50 mg BID; max dose 100 to 200 mg BID. Taper if discontinued (4)[A].
- Pregabalin: Start with 75 mg BID, titrate over 1 week to 150 mg BID; max dose 450 mg/day (some authorities recommend up to 600 mg daily) divided BID–TID (4)[A]
- Cyclobenzaprine 5 mg qHS; titrate to 10 mg BID–TID as tolerated.

**Second Line**
Gabapentin: Start at 300 mg HS, titrate to 1,200 to 2,400 mg/day divided BID–TID; max dose 3,600 mg daily
- Venlafaxine XR 37.5 to 225 mg; likely to be as effective as other SNRIs ( duloxetine, milnacipran)
- Tramadol 50 to 100 mg q6h; likely more effective in combination with acetaminophen
- Quetiapine 25 to 100 mg qHS (5)[B]
- Several agents have shown some promise of benefit, albeit with limited evidence, including pramipexole, memantine, low-dose naltrexone, medical cannabis, and hyperbaric O₂ therapy.
- Cholecalciferol may be beneficial in patients with low 25-OH vitamin D levels.

ISSUES FOR REFERRAL
In cases of unclear diagnosis or poor response to therapy, refer to rheumatology, neurology, and/or pain management.

ADDITIONAL THERAPIES
- Trigger point (not tender point) injections for regional myofascial dysfunction may provide relief.
- Multidisciplinary rehab (specialized clinic with physical medicine and therapy, occupational therapy, and integrated pain management)
- Ineffective or dangerous treatment modalities
  - NSAIDs, full-agonist opioids (except in refractory cases), benzodiazepines, SSRIs (although may have efficacy in combination therapy with TCAs or pregabalin), magnesium, guaifenesin, thyroxine, corticosteroids, DHEA, valacyclovir, interferon, calcitonin, nabilone, and antiepileptic agents (other than those listed above) (5)[A]
  - Fibromyalgia often presents concurrently with other pain syndromes that may respond to NSAIDs, corticosteroids, opioids, and other agents.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Acupuncture and electroacupuncture, biofeedback, hypnotherapy
- Balneotherapy (mineral-rich baths)
- Yoga, tai chi (3)[B], and qi gong
- Mindfulness-based meditation
- Topical phototherapy
- Myofascial massage—short- to medium-term benefit
- Limited double-blind trials have shown effectiveness of supplementation with S-adenosyl-l-methionine and acetyl-L-carnitine
- Weak evidence for transcranial direct current and other forms of cranial electrical stimulation
- Likely to be ineffective: chiropractic treatment, multivitamin therapy, homeopathy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- For efficacy of initial therapy: at 2- to 4-week intervals, then every 1 to 6 months, tailored to patient’s needs
- Advance exercise gradually to maintain tolerability.
**DIET**
No specific diet is recommended, but patient should make healthy choices and address negative dietary habits. Caloric or carbohydrate restriction may be helpful in obese patients.

**PROGNOSIS**
- 50% with partial remission after 2 to 3 years of therapy; complete remission possible but rare
- Typically has fluctuating, chronic course
- Poorer outcomes tied to greater duration and severity of symptoms, depression, obesity, insufficient engagement and “ownership” of the treatment plan, advanced age, and lack of social support.

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**
Algorithm: Fatigue

**CODES**
- ICD10
  - M79.7 Fibromyalgia

**CLINICAL PEARLS**
- Fibromyalgia is a disease of central sensitization; it is not a somatoform disorder and is not merely a manifestation of depression or anxiety. As with all chronic pain syndromes,
fibromyalgia is frequently associated with mood and anxiety disorders.

- Use ACR criteria to make the formal diagnosis of fibromyalgia.
- The best clinical outcomes occur in patients who understand their illness and actively engage in a multimodal treatment plan that includes exercise, sleep hygiene, and other lifestyle modifications, along with appropriate pharmacotherapy and CBT.
FOLLICULITIS
David C. Cadena Jr., MD

BASICS

DESCRIPTION
● Inflammation of a hair follicle (1). Subtypes include perifolliculitis and pseudofolliculitis, which occur around the follicle.
● Can occur anywhere on the body where hair is found
● Most frequent symptom is pruritus.
● Painless or tender pustules, vesicles, or pink/red papulopustules up to 5 mm in size
● Most commonly infectious in etiology:
  – *Staphylococcus aureus* bacteria
  – *Pseudomonas aeruginosa* infects areas of the body exposed to poorly chlorinated hot tubs, pools, or contaminated water.
  – *Aeromonas hydrophila* with recreational water exposure
  – Fungal (*dermatophytic, Pityrosporum, Candida*)
  – *Viral* (*VZV, herpes simplex virus [HSV]*)
  – Parasitic (*Demodex* spp. mites, *schistosomes*)
● Noninfectious types
  – Acneiform folliculitis
  – Actinic superficial folliculitis
  – Acne vulgaris
  – Keloidal folliculitis
  – Folliculitis decalvans
  – Perioral dermatitis
  – *Fox-Fordyce disease*
  – Pruritus folliculitis of pregnancy
  – Eosinophilic pustular folliculitis (three variants: Ofuji disease in patients of Asian descent, HIV positive/immunocompromised, infantile)
  – Toxic erythema of the newborn
  – Eosinophilic folliculitis (seen in HIV positive/immunocompromised)
  – Follicular mucinosis
● Skin disorders that may produce a follicular eruption:
  – Pseudofolliculitis barbae: similar in appearance; occurs after shaving; affects the face, scalp, pubis, and legs; known as razor bumps, occurs frequently in black men
  – *Atopic dermatitis*
  – *Follicular psoriasis*
  – *Rosacea*

EPIDEMIOLOGY
Affects persons of all ages, gender, and race. African ethnicities more predisposed to certain types of folliculitis

ETIOLOGY AND PATHOPHYSIOLOGY
Predisposing factors to folliculitis
- Chronic staphylococcal carrier
- Diabetes mellitus
- Malnutrition
- Pruritic skin disease (e.g., scabies, eczema)
- Exposure to poorly chlorinated swimming pools/hot tubs or water contaminated with P. aeruginosa, A. hydrophila, or schistosomes
- Occlusive corticosteroid use (for multiple hours)
- Bacteria
  - Most frequently due to S. aureus (increasing number of methicillin-resistant S. aureus [MRSA] cases)
  - Also due to Streptococcus species, Pseudomonas (following exposure to water contaminated with the species), or Proteus
  - May progress to furunculosis (painful pustular nodule with central necrosis that leaves a permanent scar after healing)
- Fungal
  - Dermatophytic (tinea capitis, tinea corporis, tinea pedis)
  - Pityrosporum (Pityrosporum orbiculare) commonly affecting teenagers and men, predominantly on upper chest and back
  - Candida albicans, although rare, has been reported with broad-spectrum antibiotic use, glucocorticoid use, immunosuppression, and in those who abuse heroin, resulting in candidemia that leads to pustules and nodules in hair-bearing areas.
- Viral
  - HSV
  - Molluscum contagiosum
- Parasitic
  - Demodex spp. mites (most commonly Demodex folliculorum), common around nasolabial area
  - Schistosomes (swimmer’s itch)
- Acneiform type commonly drug induced (systemic and topical corticosteroids, lithium, isoniazid, rifampin), EGFR inhibitors
- Severe vitamin C deficiency, scurvy
- Actinic superficial type occurs within 24 to 48 hours of exposure to the sun, resulting in multiple follicular pustules on the shoulders, trunk, and arms.
- Acne vulgaris
- Keloidal folliculitis is a chronic condition affecting mostly black patients; involves the neck and occipital scalp, resulting in hypertrophic scars and hair loss; usually consequence of uncontrolled folliculitis barbae
- Folliculitis decalvans is a chronic folliculitis that leads to progressive scarring and alopecia of the scalp.
- Rosacea consists of papules, pustules, and/or telangiectasias of the face; individuals are genetically predisposed; can be confused with folliculitis
- Fox-Fordyce disease affects the skin containing apocrine sweat glands (i.e., axillae), resulting in chronic pruritic, annular, follicular papules.
- Eosinophilic pustular folliculitis has three variants: classic (Ofuji disease), associated with HIV infection, and infantile.
Toxic erythema of the newborn is a self-limiting pustular eruption usually appearing during the first 3 to 4 days of life and subsequently fading in the following 2 weeks.

Malassezia infections in adult males with lesions on trunk (2)

**RISK FACTORS**
- Hair removal (shaving, plucking, waxing, epilating agents)
- Other pruritic skin conditions: eczema, scabies
- Occlusive dressing or clothing
- Personal carrier or contact with MRSA-infected persons
- Diabetes mellitus
- Immunosuppression (medications, chemotherapy, HIV)
- Use of hot tubs or saunas
- Use of EGFR inhibitors
- Chronic antibiotic use (gram-negative folliculitis)
- Tattoo recipient

**GENERAL PREVENTION**
- Good hygiene practices
  - Wash hands frequently.
  - Antimicrobial soap
  - Wash towels, clothes, and linens frequently with hot water to avoid reinfection.
- Good hair removal practices
  - Exfoliate beforehand.
  - Use witch hazel, alcohol, or Tend Skin afterward.
  - Shave in direction of hair growth; use shaving gel and moisturizer.
  - Decrease frequency of shaving.
  - Use clippers primarily or single-blade razors if straight shaving is desired.

**COMMONLY ASSOCIATED CONDITIONS**
- Impetigo
- Scabies
- Acne
- Follicular psoriasis
- Eczema
- Xerosis
- Staphylococcus/MRSA colonization

**DIAGNOSIS**

**HISTORY**
- Recent use of hot tubs, swimming pools, topical corticosteroids, certain hair styling and shaving practices, antibiotics or systemic steroids
- HIV status
- History of STDs (specifically syphilis)
- MRSA exposures/carrier status
- Home and work environment (risk/exposure potential)
- Pityrosporum folliculitis occurs more often in warm, moist climates.
Inquire about the timeline in which the lesions have occurred, including previous similar episodes.

**PHYSICAL EXAM**
- Characteristic lesions are 1- to 5-mm–wide vesicles, pustules, or inflamed papules with surrounding erythema.
- Rash occurs on hair-bearing skin, especially the face (beard), proximal limbs, scalp, and pubis.
- Pseudomonal folliculitis appears as a widespread rash, mainly on the trunk and limbs.
- In pseudofolliculitis barbae, the growing hair curls around and penetrates the skin at shaved areas.

**DIFFERENTIAL DIAGNOSIS**
- Acne vulgaris/acneiform eruptions
- Arthropod bite
- Contact dermatitis
- Perioral dermatitis
- Cutaneous candidiasis
- Milia
- Atopic dermatitis
- Follicular psoriasis
- Hidradenitis suppurativa

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Diagnosis is usually made clinically, taking risk factors, history, and locations of lesions into account.
- Culture and Gram stain may be done for larger lesions lancing or unroofing the pustule.
- KOH preparation as well as Wood lamp fluorescence to identify Candida or yeast
- Tzanck smear where suspicion of herpetic simplex viral folliculitis is high
- Ultrasound can be performed for questionably deeper seeding infections.

**Follow-Up Tests & Special Considerations**
- If risk factors or clinical suspicion exist, consider serologies for HIV or syphilis.
- If recurrent, consider HIV testing and A1C/fasting blood sugar testing to evaluate for diabetes.
- Consider punch biopsy with uncertain diagnosis.
- Treat positive bacterial culture according to sensitivities.
- Positive HIV serology: Follow up with CD4 count and punch biopsy to rule out eosinophilic folliculitis.

**TREATMENT**

**GENERAL MEASURES**
- Lesions usually resolve spontaneously.
- Avoid shaving and waxing affected areas (3)[C].
- Warm compresses may be applied TID.
- Systemic antibiotics are typically unnecessary.
- Topical mupirocin may be used in presumed S. aureus infection (4)[B].
Topical antifungals for fungal folliculitis (2)[B]

Preventive measures:
- Antibacterial soaps (Dial soap, chlorhexidine, or benzoyl peroxide wash when showering/bathing)
- Bleach baths (1/2 cup of 6% bleach per standard bathtub and soak for 5 to 15 minutes followed by water, rinse 1 to 2 times a week)
- Keep skin intact; daily skin care with noncomedogenic moisturizers; avoid scratching.
- Avoid trauma to skin: Use an electric razor as able.
- Clean shaving instruments daily or use disposable razor, disposing after one use (5)[B].
- Change washcloths, towels, and sheets daily.

MEDICATION
Antiseptic and supportive care is usually enough. Systemic antibiotics may be used with questionable efficacy.

First Line
- Staphylococcal folliculitis
  - Mupirocin ointment applied TID for 10 days
  - Cephalosporin (cephalexin): 250 to 500 mg PO QID for 7 to 10 days
  - Dicloxacillin: 250 to 500 mg PO QID for 7 to 10 days
- For MRSA
  - Bactrim DS: 1 to 2 tablets (160 mg/800 mg) BID PO for 5 to 10 days
  - Clindamycin: 300 mg PO TID for 10 to 14 days
  - Minocycline: 200 mg PO initially and then 100 mg BID for 5 to 10 days
  - Doxycycline: 50 to 100 mg PO BID for 5 to 10 days
- Pseudomonas folliculitis
  - Topical dilute acetic acid baths
  - Ciprofloxacin: 500 to 750 mg PO BID for 7 to 14 days only if patient is immunocompromised or lesions are persistent
- Eosinophilic folliculitis/eosinophilic pustular folliculitis
  - HAART treatment for HIV positive–related causes. Consider referral to appropriate treatment center.
  - High-potency topical corticosteroids for inflammation
  - Antihistamines (hydroxyzine, cetirizine) to control itching
  - Can consider: tacrolimus topically BID or
  - Isotretinoin 0.5 mg/kg/day PO with caution
  - Itraconazole or metronidazole

Fungal folliculitis
- Topical antifungals: ketoconazole 2% cream or shampoo or selenium sulfide shampoo daily or
- Econazole cream applied to affected area BID for 2 to 3 weeks
  - Systemic antifungals for relapses fluconazole (100 to 200 mg/day for 3 weeks) or
  - itraconazole (200 mg/day for 1 week) or griseofulvin (500 mg/day for 2 to 4 weeks)
  - Do not use oral ketoconazole due to risk of liver failure.

Parasitic folliculitis
- 5% permethrin: Apply to affected area, leave on for 8 hours, and wash off.
- Ivermectin: 200 µg/kg PO and repeat in 1 to 2 weeks if topical application unsuccessful.
Herpetic folliculitis
- Valacyclovir: 500 mg PO TID for 5 to 10 days or
- Famciclovir: 500 mg PO TID for 5 to 10 days or
- Acyclovir: 200 mg PO 5 times daily for 5 to 10 days

ISSUES FOR REFERRAL
Unusual or persistent cases should be biopsied and then referred to dermatology.

ADDITIONAL THERAPIES
- Stay informed: Testing strips can be used to test hot tubs and pools. This will help determine proper chlorine levels.
- Both hot tubs and pools should have a pH level of 7.2 to 7.8.

SURGERY/OTHER PROCEDURES
Incision and drainage is unlikely to be necessary and typically not preferred due to potential for scar formation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Resistant cases should be followed every 2 weeks until cleared.
- Consider prompt system therapy for worsening cases.

DIET
Caloric monitoring for obese patients; weight reduction will decrease risk of skin trauma and distension.

PATIENT EDUCATION
- Avoid shaving in involved areas.
- Monitor hot tub and pools.

PROGNOSIS
- Usually resolves with treatment; however, S. aureus carriers may experience recurrences.
- Mupirocin nasal treatment for carrier status and for family/household members might be helpful.
- Resistant or severe cases may warrant testing for diabetes mellitus or immunodeficiency (HIV).

COMPLICATIONS
- Primary complication is recurrent folliculitis.
- Extensive scarring with hyperpigmentation
- Progression to furunculosis or abscesses

REFERENCES

ADDITIONAL READING

SEE ALSO

Algorithm: Rash

CODES

ICD10
- L73.9 Follicular disorder, unspecified
- L66.2 Folliculitis decalvans
- L73.8 Other specified follicular disorders

CLINICAL PEARLS
• Folliculitis lesions are typically 1- to 5-mm clusters of pruritic erythematous papules and pustule surrounding hair follicles.
• Most commonly due to S. aureus. If community has increased incidence of MRSA, consider anti-MRSA treatment.
  – It is extremely important to educate patients on proper hygiene and skin care techniques to prevent chronic or recurrent cases.
Food Allergy
Stanley Fineman, MD

Basics

Description
- Hypersensitivity reaction related to certain food exposures
- System(s) affected: gastrointestinal (GI), hemic/lymphatic/immunologic, pulmonary, skin/exocrine
- Synonym(s): allergic bowel disease; dietary protein sensitivity syndrome

Epidemiology
- Predominant age: all ages but more common in infants and children
- Predominant sex: male > female (2:1)

Incidence
~2.5% of infants experience hypersensitivity reactions to cow’s milk in their 1st year of life (1)[B].

Prevalence
- The prevalence of IgE-mediated food allergy assessed by food challenge is 3% (1)[B].
- The self-reported prevalence of food allergy is 12% in children and 13% in adults (1)[B].
- In young children, the most common food allergies are cow’s milk (2.5%), egg (1.3%), peanut (0.8%), and wheat (0.4%) (2)[B].
- Adults more commonly have allergies to shellfish (2%), peanuts (0.6%), tree nuts (0.5%), and fish (0.4%).
- Food allergy is frequently a transient phenomenon; only 3–4% of children >4 years of age have persisting food allergy (2)[B].
- 20% of children with peanut protein allergy may outgrow their sensitivity by school age.

Etiology and Pathophysiology
Allergic response triggered by immunologic mechanisms (e.g., IgE-allergic response) or non–immunologic-mediated mechanisms
- Any ingested substance can cause allergic reactions:
  - Most commonly implicated foods include cow’s milk, egg whites, wheat, soy, peanuts, fish, tree nuts (walnut and pecan), and shellfish.
- Several food dyes and additives may elicit non–IgE-mediated allergic-like reactions.

Genetics
In families with a history of food hypersensitivity, the probability of food allergy in subsequent siblings may be as high as 50%.

Risk Factors
- Patients with allergic or atopic predisposition have increased risk of hypersensitivity reaction to food.
- Family history of food hypersensitivity
GENERAL PREVENTION

- Avoid the offending food.
- In patients at risk for anaphylaxis, epinephrine autoinjectors should be readily available.

DIAGNOSIS

HISTORY

- Symptoms after food ingestion/exposure—usually within 30 minutes of ingestion but could be delayed 4 to 8 hours
- Document a temporal relationship between symptoms and suspected food. Include manner in which food was prepared and quantity of food ingested
- Differentiate true food allergy/hypersensitivity from food intolerance, which may present with similar symptoms.
  - GI
    - More common: nausea, vomiting, diarrhea, abdominal pain, occult bleeding, flatulence, and bloating
    - Less common: malabsorption, protein-losing enteropathy, eosinophilic enteritis, colitis
  - Skin
    - More common: urticaria/angioedema, atopic dermatitis, pallor, or flushing
    - Less common: contact rashes
  - Respiratory
    - More common: allergic rhinitis, asthma and bronchospasm, stridor, cough, serous otitis media
    - Less common: pulmonary infiltrates (Heiner syndrome), pulmonary hemosiderosis
  - Neurologic
    - Less common: migraine headaches
  - Other
    - Systemic anaphylaxis, vasculitis; ocular injection, conjunctival edema, periorbital swelling
    - Associated factors--exercise; NSAID use; alcohol consumption

PHYSICAL EXAM

- Vital signs; growth parameters
- Signs of allergic disease—pulmonary, skin exam in particular
- Other exam findings based on clinical presentation

DIFFERENTIAL DIAGNOSIS

- GI (irritable bowel syndrome, celiac sprue, dumping syndrome, inflammatory bowel diseases, etc.), dermatologic, respiratory, neurologic, psychiatric (generalized anxiety disorder, personality disorders, etc.)
- Oral allergy syndrome
  - The oral allergy syndrome is the result of cross-reacting proteins in pollens (e.g., patients sensitive to birch tree pollen frequently have cross-reactivity to fresh apples and pears).
- Galactose-α-1,3-galactose (α-gal)
  - Following a lone star tick bite, susceptible patients may develop an IgE sensitivity to α-gal which manifests as delayed anaphylaxis presenting 3 to 6 hours after ingestion of mammalian meat. Diagnosis is by history and confirmed by specific IgE to α-gal (3).
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- CBC with differential: Eosinophilia suggests atopy.
- Serum IgA antitissue transglutaminase (IgA-anti-tTG)
- Epicutaneous (prick or puncture) allergy skin tests document IgE-mediated immunologic hypersensitivity using commercially available extracts (variable sensitivities) or fresh food skin testing.
- Skin testing using the suspect food is helpful. If negative on skin test, an oral challenge may aid in diagnosis. The overall correlation between commercially available allergy skin testing and oral food challenge is 60%, increasing to 90% when fresh food skin testing is done (i.e., the positive skin test correlates with a positive challenge).
  - Skin testing has a high sensitivity (low false-negative rate) but a low specificity (high false-positive rate), so only skin test against antigens found on history (4)[C].
- Food-specific IgE assays (radioallergosorbent test [RAST] and fluorescent enzyme immunoassay [FEI]) detect specific IgE antibodies to offending foods and are less sensitive to skin testing.
  - Using a serum assay alone to diagnose food allergy can result in misdiagnosis of true food allergic sensitivity, particularly in children with atopic dermatitis. Do not use a panel. Test for specific IgE to foods based on patient history.
- Periodic monitoring of peanut-specific IgE levels every 2 years may be helpful. If the level of peanut-specific IgE falls to <0.5 kU/L, a supervised oral challenge can be helpful. Consider a fresh food skin test with peanut protein prior to the oral challenge (4)[B].
- Component-resolved diagnosis (CRD) is a new diagnostic tool that measures specific allergenic proteins in various foods to identify specific IgE to allergenic proteins rather than whole allergen; particularly helpful for certain nuts (e.g., peanuts) (5)[B].
- Patch testing for patients with eosinophilic esophagitis and atopic dermatitis to determine delayed-sensitivity immunologic reactions is of marginal benefit (1)[B].
- Widespread allergy skin testing or serum IgE tests are not recommended because of their poor predictive value without a clinical correlating history (2)[B].
- Leukocyte histamine release assays for circulating immune complexes are of limited clinical use (2)[B].
- Provocative injection and sublingual tests are of little benefit for diagnosis of food allergy.
- The leukocytotoxic assay is unproven (1)[B].
- Other unproven diagnostic procedures that are not recommended include provocative neutralization, lymphocyte stimulation, hair analysis, and applied kinesiology (2)[B].

Diagnostic Procedures/Other
Elimination and challenge testing is best for confirming food allergy:
- Eliminate the suspected food from the diet for 1 to 2 weeks.
- Monitor the patient’s symptoms. If they disappear or substantially improve, perform an oral challenge with the suspected food under medical supervision.
- Optimally, this challenge should be performed in a double-blind, placebo-controlled manner.
- Patients with history of anaphylaxis should not have an oral challenge without a documented lack of IgE sensitivity.
- Most allergic reactions occur within 30 minutes to 2 hours after challenge. Late reactions have been described up to 12 to 24 hours.
Consider referral to gastroenterology for endoscopy and continue monitoring carefully if history and testing are inconclusive.

**Test Interpretation**
Pathologic findings on tissue biopsy are uncommon in food allergies; inflammatory changes can sometimes be seen in the GI tract. The diagnosis of eosinophilic esophagitis is defined by >15 to 20 eosinophils per high-power field on esophageal biopsy (2)[C].

**TREATMENT**

**GENERAL MEASURES**
- Offending food avoidance is the most effective treatment.
- Patients with severe food allergy should be meticulous about food avoidance. They should carry epinephrine for self-administration in the event that the offending food is ingested unknowingly and an immediate reaction develops.
- Immunotherapy may be effective for certain food allergies. Oral immunotherapy (OIT), sublingual immunotherapy (SLIT), and epicutaneous immunotherapy (EPIT) are still considered experimental and are not recommended for patients who are not participating in appropriately controlled and monitored clinical trials.
- Immunotherapy or hyposensitization with food extracts are not recommended. Research studies are in progress, but immunotherapy is considered experimental at this time.

**MEDICATION**
- Patients with significant type 1, IgE-mediated hypersensitivity should have epinephrine available for autoinjection in case of an anaphylactic reaction.
- After receiving epinephrine for a systemic anaphylactic reaction to a food, patients should be monitored in a medical facility (15–25% of patients may require >1 dose of epinephrine).
- Symptomatic treatment for milder reactions with antihistamines is generally adequate.
- Cromolyn is not recommended for use in most patients with food allergy.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Benefits of herbal medicines in food allergy are inconclusive.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
As needed

**DIET**
- As determined by tests and clinical evaluation
- Strict avoidance of offending food

**PATIENT EDUCATION**
- Dietary counseling is advised to maintain a nutritionally sound diet avoiding foods to which the patient is sensitive.
PROGNOSIS

Most infants outgrow food hypersensitivity by 2 to 4 years:
- It may be possible to reintroduce the offending food cautiously into the diet (especially if a particular food is difficult to avoid). Check food-specific IgE by fresh food allergy skin test to ensure negative prior to oral challenge.
- 20% of peanut allergies resolve by age 5 years.
- 42% of children with egg allergy and 48% of children with milk allergy develop clinical tolerance and lose their sensitivity over time (1)[C].

Adults with food hypersensitivity (particularly to milk, fish, shellfish, or nuts) tend to maintain their allergy for many years (2)[B].

COMPLICATIONS

- Anaphylaxis
- Angioedema
- Bronchial asthma
- Enterocolitis
- Eosinophilic esophagitis
- Eczematoid lesions

Anaphylaxis; Celiac Disease; Irritable Bowel Syndrome

CODES

ICD10
- T78.1XXA Oth adverse food reactions, not elsewhere classified, init
- T78.00XA Anaphylactic reaction due to unspecified food, init encntr
- L27.2 Dermatitis due to ingested food

CLINICAL PEARLS
- Up to 20% of children with peanut allergy may outgrow their sensitivity.
- Oral itching following ingestion of fresh fruit may be a warning for anaphylaxis.
- Maternal dietary restrictions during pregnancy and lactation do not appear to prevent atopic disease in infants.
- Breastfeeding is recommended for the first 6 months of life, particularly when there is a family history of atopy and food allergy.
- Delaying the introduction of solid foods beyond 6 months does not appear to have a significant protective effect on the development of allergies.
- Children 4 to 11 months of age with eczema or other food allergy may benefit from early introduction of peanut protein. Consider allergy skin testing prior to introducing peanut protein.
FOOD POISONING, BACTERIAL
Michael B. Kalinowski, DO, MS ● Irfan H. Siddiqui, MD

BASICS

DESCRIPTION
● Results from the consumption of contaminated food or water
● Symptoms commonly include vomiting, diarrhea, dehydration, abdominal discomfort, and fever (1).
● Foodborne illness may be caused by bacterial, parasitic, or viral infection (2).

EPIDEMIOLOGY
● The cause is unclear in up to 80% of foodborne illness.
● Bacterial pathogens most commonly contributing to foodborne illness are Salmonella (nontyphoidal), Campylobacter, Clostridium perfringens, Staphylococcus aureus, Listeria monocytogenes, and Escherichia coli (1).
● Norovirus is the most common viral cause of foodborne illness in the United States (3).

Incidence
Roughly 1 in 6 Americans (48 million) become ill, 128,000 are hospitalized, and 3,000 die of foodborne diseases annually.

ETIOLOGY AND PATHOPHYSIOLOGY
● Short incubation period (1 to 6 hours)
  – Bacillus cereus toxin
    o Toxin can tolerate high temperatures
    o Food sources: improperly cooked rice/fried rice and red meats (2)
    o Symptoms: sudden onset of severe nausea. Vomiting and diarrhea may or may not be present.
  – S. aureus (1)
    o Toxin mediated
    o Food sources: nonrefrigerated or improperly refrigerated meats and potato and egg salads
    o Symptoms: sudden onset of severe nausea and vomiting. Abdominal cramps and fever may be present.
● Medium incubation period (8 to 16 hours)
  – B. cereus (1)
    o Food sources: meat, stews, gravy, vanilla sauce
    o Symptoms: watery diarrhea, abdominal cramps, nausea
  – C. perfringens (1,2)
    o Food sources: dry/precooked or undercooked meats, home-canned goods
    o Symptoms: watery diarrhea, nausea, abdominal cramps
● Long incubation period (>16 hours)
  – Toxin-producing organisms:
    o Clostridium botulinum (1)
      • Food source: commercially canned or improperly home-canned foods
      • Symptoms: vomiting, diarrhea, slurred speech, diplopia, dysphagia, and descending
muscle weakness/flaccid paralysis

- Enterohemorrhagic E. coli (e.g., 0157:H7) (1,2)
  - Food sources: undercooked ground beef, juice, unpasteurized milk, raw produce, and contaminated water
  - Risk factors: childcare centers, nursing homes, extremes of age
  - Symptoms: severe diarrhea that often becomes bloody, abdominal pain, vomiting

- Enterotoxigenic E. coli (“traveler’s diarrhea”) (4)
  - Food sources: food or water contaminated by human feces
  - Symptoms: watery diarrhea, abdominal cramps, tenesmus, fecal urgency, and vomiting

- Vibrio cholerae (2)
  - Food sources: contaminated water, fish, and shellfish, especially food sold by street vendors
  - Symptoms: profuse watery “rice water” diarrhea and vomiting, which can lead to severe dehydration and rapid death

- Invasive organisms
  - Salmonella, nontyphoidal (1,2,3)
    - Food sources: contaminated eggs, poultry; unpasteurized milk or juice, cheese; contaminated raw fruit and vegetables; and contaminated peanut butter
    - Risk factors: contact with animals
    - Symptoms: small volume, mucopurulent and possibly bloody diarrhea; fever; abdominal cramps; vomiting

- Campylobacter jejuni (1,2)
  - Food sources: raw and undercooked poultry, unpasteurized milk, and contaminated meats
  - Symptoms: diarrhea (possibly bloody), cramps, vomiting, fever

- Shigella (1,2)
  - Food sources: contaminated water, raw produce, uncooked foods, foods handled by infected food worker
  - Risk factors: Men who have sex with men (MSM)
  - Symptoms: abdominal cramps, fever, mucopurulent and bloody diarrhea

- Vibrio parahaemolyticus (1,2)
  - Food source: undercooked or raw seafood, especially shellfish
  - Risk factors: cirrhosis
  - Symptoms: nausea, vomiting, diarrhea, abdominal pain

- Vibrio vulnificus (1,2)
  - Food source: undercooked or raw seafood, particularly oysters
  - Symptoms: vomiting, diarrhea, abdominal pain, bacteremia, wound infections; can be fatal in patients with liver disease or those who are immunocompromised

- Yersinia enterocolitica (2)
  - Food sources: undercooked beef and pork, unpasteurized milk, tofu, contaminated water
  - Risk factors: cirrhosis, hemochromatosis, blood transfusion
  - Symptoms: abdominal pain, fever, diarrhea (possibly bloody), vomiting

- L. monocytogenes (1)
  - Food sources: unpasteurized/contaminated milk, soft cheese, and processed deli meats
  - Risk factors: pregnancy
Symptoms: nausea, vomiting, fever, watery diarrhea; pregnant women may have a flu-like illness leading to premature delivery or stillbirth; immunocompromised patients may develop meningitis and bacteremia.

RISK FACTORS
- Recent travel to a developing or underdeveloped countries (3)
- Food handlers, childcare attendees, nursing home residents, recently hospitalized patients or patients recently exposed to antibiotics (2)
- Altered immunity due to underlying disease or use of certain medications, including antacids, H2 blockers, and proton pump inhibitors (3)
- Cross-contamination and subsequent ingestion of improperly prepared and stored foods

GENERAL PREVENTION
- When preparing food:
  - Wash hands, cutting boards, and food preparation surfaces before and after preparing each item
  - Wash fresh produce thoroughly before consuming
  - Keep raw meat, poultry, fish, and their juices away from other food (e.g., salad). Wear gloves when handling raw meats (5).
  - Do not put cooked protein or washed produce into containers or on surfaces where unwashed or raw food was stored.
  - Thoroughly cook meat to the following internal temperatures:
    - Fresh beef, veal, pork, and lamb: 145°F
    - Ground meats and egg dishes: 160°F
    - Poultry: 165°F
    - Cook eggs thoroughly until the yolk is firm.
    - Seafood: 145°F
  - Refrigerate leftovers within 2 to 3 hours in clean, shallow, covered containers. If the temperature is >90°F, refrigerate within 1 hour.
- When traveling to underdeveloped countries:
  - Eat only freshly prepared foods.
  - Avoid beverages and foods prepared with nonpotable water.
  - Other risky foods include raw or undercooked meat and seafood, unpeeled raw fruits, and vegetables.
  - Bottled, carbonated, and boiled beverages are generally safe to drink.
- Improved hygiene and sanitation reduces the risk of traveler’s diarrhea. The prevention strategy “Boil it, Cook it, Peel it, or Forget it” is easy to remember and may be of use, although there is inconsistent and limited evidence to overall benefit (4).
- Chemoprophylaxis for traveler’s diarrhea is recommended for high-risk travelers (e.g., immunocompromised) (4).

DIAGNOSIS

HISTORY
- Onset, duration, frequency, severity, and character (e.g., watery, bloody, mucus-filled) of diarrhea (2)
The definition of diarrhea is >3 or more unformed stools daily or the passage of >250 g of unformed stools per day (3).

Suspect bacterial food poisoning when multiple persons have rapid onset of symptoms after eating the same meal; high fever, blood, or mucus in stool; severe abdominal pain; signs of dehydration; or recent travel to a foreign country (2,3).

Further evaluation and treatment with high fever (≥101.3°F), ≥6 stools per day, blood in the stools, elevated white blood cell count, signs of dehydration, or diarrheal illness that lasts >2 to 3 days (3).

**PHYSICAL EXAM**
- Key signs of dehydration: delayed capillary refill, decreased skin turgor, dry mucous membranes, and orthostatic hypotension (2).
- Fever may suggest invasive or toxin-producing bacteria (2).
- Abdominal exam: Assess for pain, peritoneal signs, and bowel activity to differentiate from other acute abdominal processes (2).
- Rectal exam for blood, rectal pain, stool consistency

**DIFFERENTIAL DIAGNOSIS**
- Other infectious gastrointestinal illnesses (i.e., viral or parasitic)
- Clostridium difficile colitis
- Inflammatory bowel disease
- Appendicitis
- Acute cholecystitis
- Acute diverticulitis
- Acute hepatitis
- Malabsorption

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- For mild, self-limiting illness, a stool culture is not typically necessary and is unlikely to change management (1)[C].
- Testing for fecal leukocytes and fecal occult blood is not mandatory unless patients have fever or bloody diarrhea (5).
- Consider ova and parasites if dehydration, history of foreign travel, or symptoms lasting >2 weeks (3).
- CBC, basic metabolic profile for severe cases with dehydration, inpatient, and nursing home exposure (3)
- Consider endoscopic evaluation for severe cases (3,5,6). Have a low threshold for endoscopy among patients with AIDS and persistent diarrhea (5).
- Abdominal CT may be helpful when intra-abdominal pathology is in the differential and clinical presentation is unclear (3,5).

**Follow-Up Tests & Special Considerations**
Depending on a potential outbreak, epidemiologic investigation may be warranted. Reporting requirements vary by state and organism (1).
**TREATMENT**

Most cases of food poisoning are self-limited and do not require medication.

**MEDICATION**

**First Line**
- Oral rehydration is the first-line therapy for acute diarrheal illness (2,5).
- A balanced oral rehydration solution (ORS) is particularly recommended for elderly or pediatric patients with severe diarrhea, or for travelers with severe, cholera-like watery diarrhea (6)[B].
- Most patients with mild illness do not need formal ORS and can rehydrate with fluids and salt-rich foods (6).
- Empiric antibiotic therapy is not recommended for most cases of acute diarrhea (unless traveler’s diarrhea is suspected) (6)[A].

**Second Line**
Consider antibiotics only for patients with severe illness requiring hospitalization and those with fever and hematochezia or when diagnostic testing confirms a bacterial source (1). Pathogen-specific therapy:
- B. cereus (2)
  - Supportive care only
- C. jejuni (2,3)
  - Mild: supportive care only—antibiotics may induce resistance
  - Severe: azithromycin 500 mg/day for 3 to 5 days. Fluoroquinolones are no longer recommended due to resistance (1).
- C. botulinum
  - Supportive care only. Antitoxin can be helpful early during illness.
- C. perfringens
  - Supportive care only
- Enterohemorrhagic E. coli (e.g., 0157:H7) (3)
  - Supportive care only. Closely monitor renal function, hemoglobin, and platelets. Infection associated with hemolytic uremic syndrome (HUS). Avoid antibiotics because they may increase risk.
- Enterotoxigenic E. coli (common cause of traveler’s diarrhea) (2,3,4)
  - Generally self-limited. Antibiotics shorten course of illness (4)[A].
  - Ciprofloxacin 500 mg BID or 750 mg daily for 1 to 3 days; azithromycin 1 g × single dose or daily for 3 days; or rifaximin 200 mg TID for 3 days
- Salmonella, nontyphoidal (2,3,4,6)
  - No therapy in mild disease (Antibiotics may lengthen shedding.)
  - Moderate: ciprofloxacin 500 mg BID for 5 to 7 days, levofloxacin 500 mg daily for 7 to 10 days, or TMP/SMX DS 160/800 mg BID for 5 to 7 days
  - Severe diarrhea, immunocompromised, systemic signs, positive blood cultures: IV ceftriaxone 1 to 2 g daily for 7 to 10 days
- Shigella (2,3,6)
  - Ciprofloxacin 500 mg BID or 750 mg daily for 3 days, or 2 g single dose; alternative options: azithromycin (drug of choice secondary to quinolone resistance) 500 mg BID for 3
days, TMP/SMX DS 160/800 mg BID for 5 days, or ceftriaxone 2 to 4 g single dose

- S. aureus (3)
  - Supportive care only
- Noncholeraic Vibrio (3)
  - Ciprofloxacin 750 mg daily for 3 days or azithromycin 500 mg daily for 3 days
- V. cholerae (3)
  - Doxycycline 300 mg 1-time dose in most cases, or tetracycline 500 mg QID for 3 days, or erythromycin 250 mg TID for 3 days, or azithromycin 1,000 mg as single dose or 500 mg/day for 3 days
- Yersinia (2)
  - Usually supportive care only
  - Severe: doxycycline combined with aminoglycoside; TMP/SMX DS 160/800 mg BID for 5 days; or ciprofloxacin 500 mg BID for 7 to 10 days

ADDITIONAL THERAPIES

- For severe nausea and vomiting, promethazine is effective in adults. Ondansetron is effective in children (4).
- Loperamide 4 mg initially then 2 mg after each loose stool to a maximum of 8 mg in a 24-hour period may be used unless high fever, bloody diarrhea, and/or severe abdominal pain present (signs of enteroinvasion) (4).
- Bismuth subsalicylate 525 mg QID is moderately effective in traveler’s diarrhea (4,6).
- Evidence for the effectiveness of probiotics and prebiotics is limited and inconsistent. Use is not currently recommended outside of postantibiotic-related infectious diarrhea (5,6).
- Diligent hand washing throughout the course of illness decreases spread (2).

ONGOING CARE

DIET

- Modify food intake when nausea is present or vomiting prevents intake. Drink plenty of fluids in frequent sips.
- As nausea subsides, drink adequate fluids; add in bland, low-fat meals; and rest. Avoid alcohol, coffee, nicotine, and spicy foods.
- Breastfeed nursing infants on demand. Infants and older children should be offered usual food.
- For diarrhea, consider a bland diet.
- Limiting dairy to 24 hours after last diarrhea episode may assist in symptom reduction.

PROGNOSIS

Most infections are self-limited and resolve over several days. Antibiotics for moderate to severe traveler’s diarrhea shorten duration by several days (4).

COMPLICATIONS

- Dehydration (2)
- Hemolytic uremic syndrome following E. coli 0157:H7 infection (3)
- Guillain-Barré syndrome following Campylobacter enteritis (3)
- Reactive arthritis following salmonella, shigella, or yersinia infections (3)
- Postinfectious irritable bowel (3)
REFERENCES

SEE ALSO

Appendicitis, Acute; Botulism; Brucellosis; Dehydration; Diarrhea, Acute; Guillain-Barré Syndrome; Hypokalemia; Intestinal Parasites; Salmonella Infection; Typhoid Fever

CODES

ICD10

- A05.9 Bacterial foodborne intoxication, unspecified
- A02.0 Salmonella enteritis
- A04.5 Campylobacter enteritis

CLINICAL PEARLS

- Consider bacterial food poisoning when multiple patients present with fever and blood/mucus in stool after ingesting the same food or having recently returned from a developing nation.
- Consider culture and antibiotics if there is persistent fever with blood/mucus in stool, concern for sepsis, and/or for symptoms lasting >7 days.
- Withhold antispasmodics and antidiarrheal agents if there is concern for enteroinvasion (high prolonged fever, bloody diarrhea, severe pain, septicemia).
- Consider empiric antibiotic therapy for traveler’s diarrhea in cases of moderate to severe disease.
FROSTBITE
Jeffrey D. Kueter, MD, FAAFP

BASICS

DESCRIPTION
- A severe localized injury due to cold exposure, causing tissue to freeze, resulting in direct cellular injury and progressive dermal ischemia (most commonly of exposed hands, feet, face, and ears)
- Systems affected: integumentary, vascular, muscular, skeletal, nervous
- Synonym: dermatitis congelationis

EPIDEMIOLOGY
- Predominantly adults but can affect all ages
- Predominant sex: male = female

ETIOLOGY AND PATHOPHYSIOLOGY
- Prolonged exposure to cold
- Refreezing thawed extremities
- Ice crystals form intracellularly and extracellularly.
- Vasoconstriction reduces blood flow, and microvascular endothelial injury leads to ischemia.
- Cellular dehydration leads to abnormal electrolyte concentrations and cell death.
- In severe cases, tissue injury extends to muscle and bone leading to necrosis and mummification.
- Rewarming injured endothelium results in edema and bullae.
- Inflammatory mediators such as prostaglandins and thromboxane A2 induce vasoconstriction and platelet aggregation, worsening ischemia.

RISK FACTORS
- Prolonged exposure to below freezing temperatures, especially combined with wind and/or water exposure
- High-altitude activities, such as mountaineering
- Military operations in cold environments
- Constricting or wet clothing with inadequate insulation
- Altered mental status due to alcohol, drugs, or psychiatric illness
- Homelessness
- Previous cold-related injury
- Dehydration and/or malnutrition
- Smoking
- Raynaud phenomenon
- Peripheral vascular disease
- Diabetes

GENERAL PREVENTION
- Dress in layers with appropriate cold weather gear and avoid clothing that is too constricting.
- Cover exposed areas and extremities appropriately.
- Stay dry; avoid alcohol and minimize wind exposure.
- Ensure adequate hydration and caloric intake.
- Use supplemental oxygen at very high altitudes (>7,500 meters).
- Exercise can protect against frostbite by increasing core and peripheral temperatures.
- Appropriate use of chemical or electric hand and foot warmers can help maintain peripheral warmth.

**COMMONLY ASSOCIATED CONDITIONS**
- Hypothermia
- Alcohol or drug abuse

**DIAGNOSIS**

**HISTORY**
- Significant cold exposure—determine length and severity.
- Throbbing pain
- Paresthesias
- Numbness
- Loss of coordination and dexterity

**PHYSICAL EXAM**
- Hands, feet, face, and ears are most commonly affected.
- Before rewarming, skin may be insensate, white or grayish-yellow in color, cyanotic, or hard and waxy to touch.
- After rewarming, immediate physical exam findings can be categorized as:
  - Grade 1: no cyanosis on the extremity
  - Grade 2: cyanosis isolated to the distal phalanx
  - Grade 3: intermediate and proximal phalangeal cyanosis
  - Grade 4: cyanosis over the carpal or tarsal bones (1)[C]
- Frostbite can alternatively be categorized into four degrees (similar to burn injuries):
  - 1st degree: numbness and erythema. A white or yellow, firm, slightly raised plaque develops. No gross tissue infarction occurs; there may be slight epidermal sloughing. Mild edema is common.
  - 2nd degree: superficial skin vesiculation; a clear or milky blisters, surrounded by erythema and edema
  - 3rd degree: deeper hemorrhagic blisters
  - 4th degree: extends through the dermis to involve subcutaneous tissues, with necrosis extending into muscle and bone
- 1st- and 2nd-degree injuries are superficial.
- 3rd- and 4th-degree injuries are deep (2)[C].

**DIFFERENTIAL DIAGNOSIS**
- Frostnip: a superficial cold injury that resolves spontaneously without tissue loss
- Chilblains (pernio): a localized inflammatory reaction to cold and wet exposure without tissue freezing; typically presents as edematous, erythematous to violaceous skin lesions
- Immersion foot (trench foot): inflammatory reaction of the feet to prolonged exposure to cold and moisture
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Baseline labs: complete blood count, comprehensive metabolic panel, UA for myoglobinuria, culture wound if suspected infection
- Technetium (Tc)-99m scintigraphy can identify tissue viability at early stage and identify candidates for thrombolytic therapy.
- MRI/MRA, duplex ultrasonography, and standard or digital subtraction angiography are occasionally used.
- Consider serial photographs at time of injury, at 24 hours, and every several days until hospital discharge.

TREATMENT

GENERAL MEASURES
- Correct hypothermia.
- Assess for additional injuries.
- Remove jewelry from affected extremities.
- Initiate rewarming of affected body part only if there is no risk of refreezing.
- Warm affected parts of body in 37–39°C water for approximately 30 minutes until the involved part takes on a red or purple appearance and becomes pliable to touch.
- A whirlpool bath can help with rewarming.
- Avoid using other heat sources, such as a fire or space heater to rewarm affected parts.
- Apply topical aloe vera gel before dressing.
- Selectively drain clear or cloudy blisters; leave hemorrhagic blisters intact.
- Splint and elevate affected extremity.
- Tetanus prophylaxis
- Oral hydration if patient is alert and has no GI symptoms, otherwise IV hydration with warm normal saline in small boluses
- Daily bathing in warm water with active and passive mobilization
- Dry, loose bulky dressings, including in between fingers/toes (2)[C]

ALERT
- Avoid rubbing the affected area as this can lead to further tissue damage.
- Patients should not walk on a frostbitten foot prior to definitive care.

MEDICATION
- Avoid rubbing the affected area as this can lead to further tissue damage.
- Patients should not walk on a frostbitten foot prior to definitive care.

First Line
- tPA for deep injury, administered (either IV or intra-arterially) within 24 hours of injury may prevent damage from microvascular thrombosis and reduce amputation rates (3)[B],(4)[B],(5)[B].
- Precaution: tPA should not be used with history of recent bleeding, stroke, peptic ulcer, or recent surgery.
- Heparin is recommended as adjunctive therapy in tPA protocols. Heparin is not recommended
as monotherapy (5)[C].
- Consider low-molecular-weight dextran in patients not given other systemic treatments (e.g., tPA) (2)[C].
- Aspirin 250 mg plus buflomedil 400 mg IV followed by 8 days of iloprost 0.5 to 2.0 mg/kg/min for 6 hr/day may reduce amputation rates in patients with frostbite extending to the proximal phalanx (3)[B].
- Update tetanus toxoid (2)[C].
- Ibuprofen 400 mg q12h (inhibit prostaglandins) (2)[C]
- Nonsteroidal anti-inflammatory drug for mild to moderate pain; narcotic analgesia for moderate to severe pain
- Use systemic antibiotics for proven infection. Prophylactic antibiotics are not recommended (2)[C].

Second Line
Pentoxifylline 400 mg q8 hours (6)[C]

ADDITIONAL THERAPIES
- Heated oxygen
- Warm IV fluids

SURGERY/OTHER PROCEDURES
- Urgent surgery is rarely needed.
- Fasciotomy is indicated if the patient develops elevated compartment pressures (2)[C].
- Surgical débridement, as needed, to remove necrotic tissue
- Amputation only if tissues are necrotic: may take 4 to 12 weeks for the demarcation of tissue necrosis to become definitive
- Consider imaging with $^{99m}$Tc bone scan and/or MRA in severe cases to determine extent of injury; assess viability of surrounding tissue and determine need for surgery.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Hospitalization is generally recommended unless no blisters are present after rewarming (e.g., grade 1/1st-degree frostbite) (1)[C],(2)[C].
- Patients are typically best cared for in a hospital with experience treating frostbite injuries (trauma center or burn unit).
- Administer tPA in intensive care setting.
- Ensure proper hydration and nutrition.
- Treat pain (often requires narcotic analgesia).
- Wound care—clean dressings and twice daily whirlpool baths
- Apply aloe vera gel every 6 to 8 hours through resolution of blisters.
- Elevate injured extremities above heart level to minimize edema.
- Physical therapy and early mobilization
- If patient cannot tolerate oral fluids or has altered mental status, give warmed normal saline in small boluses (2)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Protect injured body parts.
- Continue physical therapy.
- Avoid smoking.
- Avoid recurrent cold exposure.
- Ensure properly fitting clothing and footwear.

**Patient Monitoring**
- Follow-up for physical therapy progress, infection, and other complications listed below.
- Monitor growth of affected extremity in pediatric patients.

**Diet**
- As tolerated
- Warm oral fluids

**Patient Education**
Provide education on:
- Protection from cold injuries
- Risk factors for frostbite
- Early signs and symptoms of frostbite
- Field treatment of cold injuries
- Wound care

**Prognosis**
- Grade 1: no amputation and no sequelae
- Grade 2: potential soft tissue amputation and nail sequelae
- Grade 3: potential bone amputation of the digit and functional sequelae
- Grade 4: potential bone amputation of the limb with functional sequelae (1)[C]

**Complications**
- Tissue loss: Distal parts of an extremity may undergo spontaneous amputation.
- Tissue necrosis requiring amputation
- Gangrene
- Hyperhidrosis due to nerve injury
- Decreased hair and nail growth
- Raynaud phenomenon
- Changes in skin color
- Joint stiffness and arthritis
- Chronic regional pain
- Neuropathy
- Localized osteoporosis
- Premature closure of epiphyses in pediatric patients

**References**

**ADDITIONAL READING**

**SEE ALSO**

- Hypothermia
- Algorithm: Hypothermia

**CODES**

**ICD10**

- T33.90XA Superficial frostbite of unspecified sites, init encntr
- T34.90XA Frostbite with tissue necrosis of unsp sites, init encntr
- T33.829A Superficial frostbite of unspecified foot, initial encounter

**CLINICAL PEARLS**

- Frostbite is a tetanus-prone injury. Provide appropriate tetanus prophylaxis.
- Avoid rewarming en route to the hospital if there is a chance of refreezing; rewarm only with water.
- Assess for additional injuries to areas that may be insensate.
- tPA can reduce amputation rates. Use within 24 hours of injury in appropriate clinical settings.
- Early assessment of the degree of tissue involvement is difficult. Delay surgery until a definite tissue demarcation of necrosis occurs (may take 4 to 12 weeks).
FURUNCULOSIS
Zoltan Trizna, MD, PhD

BASICS

DESCRIPTION
- Acute bacterial abscess of a hair follicle (often Staphylococcus aureus)
- System(s) affected: skin/exocrine
- Synonym(s): boils

EPIDEMIOLOGY

Incidence
- Predominant age
  - Adolescents and young adults
  - Clusters have been reported in teenagers living in crowded quarters, within families, or in high school athletes.
- Predominant sex: male = female

Prevalence
Exact data are not available.

ETIOLOGY AND PATHOPHYSIOLOGY

- Infection spreads away from hair follicle into surrounding dermis.
- Pathogenic strain of S. aureus (usually); most cases in United States are now due to community-acquired methicillin-resistant S. aureus (CA-MRSA), whereas methicillin-sensitive S. aureus (MSSA) is most common elsewhere (1).

Genetics
Unknown

RISK FACTORS
- Carriage of pathogenic strain of Staphylococcus sp. in nares, skin, axilla, and perineum
- Rarely, polymorphonuclear leukocyte defect or hyperimmunoglobulin E–Staphylococcus sp. abscess syndrome
- Diabetes mellitus, malnutrition, alcoholism, obesity, atopic dermatitis
- Primary immunodeficiency disease and AIDS (common variable immunodeficiency, chronic granulomatous disease, Chédiak–Higashi syndrome, C3 deficiency, C3 hypercatabolism, transient hypogammaglobulinemia of infancy, immunodeficiency with thymoma, Wiskott-Aldrich syndrome)
- Secondary immunodeficiency (e.g., leukemia, leukopenia, neutropenia, therapeutic immunosuppression)
- Medication impairing neutrophil function (e.g., omeprazole)
- The most important independent predictor of recurrence is a positive family history.

GENERAL PREVENTION
Patient education regarding self-care (see “General Measures”); treatment and prevention are interrelated.
COMMONLY ASSOCIATED CONDITIONS
- Usually normal immune system
- Diabetes mellitus
- Polymorphonuclear leukocyte defect (rare)
- Hyperimmunoglobulin E–Staphylococcus sp. abscess syndrome (rare)
- See “Risk Factors.”

DIAGNOSIS

HISTORY
- Located on hair-bearing sites, especially areas prone to friction or repeated minor traumas (e.g., underneath belt, anterior aspects of thighs, nape, buttocks)
- No initial fever or systemic symptoms
- The folliculocentric nodule may enlarge, become painful, and develop into an abscess (frequently with spontaneous drainage).

PHYSICAL EXAM
- Painful erythematous papules/nodules (1 to 5 cm) with central pustules
- Tender, red, perifollicular swelling, terminating in discharge of pus and necrotic plug
- Lesions may be solitary or clustered.

DIFFERENTIAL DIAGNOSIS
- Folliculitis
- Pseudofolliculitis
- Carbuncles
- Ruptured epidermal cyst
- Myiasis (larva of botfly/tumbu fly)
- Hidradenitis suppurativa
- Atypical bacterial or fungal infections

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Obtain culture if with multiple abscesses marked by surrounding inflammation, cellulitis, systemic symptoms such as fever, or if immunocompromised.

Follow-Up Tests & Special Considerations
- Immunoglobulin levels in rare (e.g., recurrent or otherwise inexplicable) cases
- If culture grows gram-negative bacteria or fungus, consider polymorphonuclear neutrophil leukocyte functional defect.

Test Interpretation
Histopathology (although a biopsy is rarely needed)
- Perifollicular necrosis containing fibrinoid material and neutrophils
- At deep end of necrotic plug, in SC tissue, is a large abscess with a Gram stain positive for small collections of S. aureus.
TREATMENT

GENERAL MEASURES
- Moist, warm compresses (provide comfort, encourage localization/pointing/drainage) 30 minutes QID
- If pointing or large, incise and drain: Consider packing if large or incompletely drained.
- Routine culture is not necessary for localized abscess in nondiabetic patients with normal immune system.
- Sanitary practices: Change towels, washcloths, and sheets daily; clean shaving instruments; avoid nose picking; change wound dressings frequently; do not share items of personal hygiene (2)[B].

MEDICATION

First Line
- Systemic antibiotics usually unnecessary, unless extensive surrounding cellulitis or fever. Other indications include a single abscess >2 cm, immunocompromise.
- If suspecting MRSA, see “Second Line.”
- If multiple abscesses, lesions with marked surrounding inflammation, cellulitis, systemic symptoms such as fever, or if immunocompromised: Place on antibiotics therapy directed at S. aureus for 10 to 14 days.
  - Dicloxacillin (Dynapen, Pathocil) 500 mg PO QID or cephalexin 500 mg PO QID or clindamycin 300 mg TID, if penicillin-allergic

Second Line
- Resistant strains of S. aureus (MRSA): clindamycin 300 mg q6h or doxycycline 100 mg q12h or trimethoprim-sulfamethoxazole (TMP-SMX DS) 1 tab q8–12h or minocycline 100 mg q12h
- If known or suspected impaired neutrophil function (e.g., impaired chemotaxis, phagocytosis, superoxide generation), add vitamin C 1,000 mg/day for 4 to 6 weeks (prevents oxidation of neutrophils).
- If antibiotic regimens fail:
  - May try PO pentoxifylline 400 mg TID for 2 to 6 months
  - Contraindications: recent cerebral and/or retinal hemorrhage; intolerance to methylxanthines (e.g., caffeine, theophylline); allergy to the particular drug selected
  - Precautions: prolonged prothrombin time (PT) and/or bleeding; if on warfarin, frequent monitoring of PT

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Instruct patient to see physician if compresses are unsuccessful.

DIET
Unrestricted
PROGNOSIS
- Self-limited: usually drains pus spontaneously and will heal with or without scarring within several days
- Recurrent/chronic: may last for months or years
- If recurrent, usually related to chronic skin carriage of staphylococci (nares or on skin).
  - Treatment goals are to decrease or eliminate pathogenic strain or suppress pathogenic strain.
  - Culture nares, skin, axilla, and perineum (culture nares of family members)
  - Mupirocin 2%: Apply to both nares BID for 5 days each month.
  - Culture anterior nares every 3 months; if failure, retreat with mupirocin or consider clindamycin 150 mg/day for 3 months.
  - Long-term efficacy of strategies to eliminate carrier state (decolonization) remains unclear.
- Especially in recurrent cases, wash entire body and fingernails (with nailbrush) daily for 1 to 3 weeks with povidone-iodine (Betadine), chlorhexidine (Hibiclens), or hexachlorophene (pHisofHex soap), although all can cause dry skin.

COMPLICATIONS
- Scarring
- Bacteremia
- Seeding (e.g., septal/valve defect, arthritic joint)

REFERENCES

ADDITIONAL READING

SEE ALSO
Folliculitis; Hidradenitis Suppurativa
CODES

ICD10
- L02.92 Furuncle, unspecified
- L02.12 Furuncle of neck
- L02.429 Furuncle of limb, unspecified

CLINICAL PEARLS

- Pathogens may be different in different localities. Keep up-to-date with the locality-specific epidemiology.
- If few, furuncles/furunculosis do not need antibiotic treatment. If systemic symptoms (e.g., fever), cellulitis, or multiple lesions occur, oral antibiotic therapy is used.
- Other treatments for MRSA include linezolid PO or IV and IV vancomycin.
- Folliculitis, furunculosis, and carbuncles are parts of a spectrum of pyodermas.
- Other causative organisms include aerobic (e.g., Escherichia coli, Pseudomonas aeruginosa, and Streptococcus faecalis), anaerobic (e.g., Bacteroides, Lactobacillus, Peptobacillius, and Peptostreptococcus), and Mycobacteria.
- Decolonization (treatment of the nares with topical antibiotic) is only recommended if the colonization was confirmed by cultures because resistance is common and treatment is of uncertain efficacy.
GALACTORRHEA
Kelley V. Lawrence, MD, IBCLC, FAAFP, FABM • Chandini Rathee, MD • Elizabeth Marie Ferruzzi, MD

BASICS
Galactorrhea is a common condition in women.

DESCRIPTION
- Milky nipple discharge not associated with gestation or present >1 year after weaning.
- Galactorrhea does not include serous, purulent, or bloody nipple discharge.
- System(s) affected: endocrine/metabolic, nervous, reproductive

Pregnancy Considerations
- Most cases of galactorrhea during pregnancy are physiologic.
- Pregnancy stimulates lactotroph cells, so pituitary prolactin-secreting macroadenomas may increase by 21% (1)[A].

EPIDEMIOLOGY
- Predominant age: 15 to 50 years (reproductive age)
- Predominant sex: female > male (rare, e.g., in patients with multiple endocrine neoplasia type 1 [MEN1], the most common anterior pituitary tumors are prolactinomas)

Incidence
Prolactinomas, as a cause of galactorrhea, have a 44.4 persons per 100,000 incidence in adults (2).

Prevalence
6.8% of women referred to physicians with a breast complaint have nipple discharge. Another source defines nipple discharge as the chief complaint in 2–5% of women visiting health care providers (3). 20–25% of women experience galactorrhea in their lifetime (4)[C].

ETIOLOGY AND PATHOPHYSIOLOGY
- Lactation is stimulated by prolactin, which is secreted in pulses by the anterior pituitary, and inhibited by dopamine produced in the hypothalamus.
- Galactorrhea results either from prolactin overproduction or loss of inhibitory regulation by dopamine.
  - Afferent neural stimulation
    o Chest wall trauma
    o Chiari-Frommel, del Castillo, and Forbes-Albright syndromes
    o Herpes zoster
    o Nipple stimulation
    o Spinal cord injury
  - Organic hyperprolactinemia
    o Craniopharyngiomas
    o Irradiation
    o Meningiomas or other tumors
- Multiple sclerosis (MS) (with hypothalamic lesion)
- Pituitary stalk compression
- Post-breast augmentation surgery (1%)
- Prolactinoma
- Sarcoid
- Traumatic injury
- Vascular malformations (aneurysms)
  - Functional hyperprolactinemia
    - Adrenal insufficiency
    - Breast tissue with increased sensitivity to prolactin and/or increased prolactin receptors
    - Chronic kidney disease
    - Cirrhosis
    - Hypothyroidism
    - Lung cancer
    - Renal cell cancer
  - Medications/substances:
    - Cardiology
      - α-Methyldopa
      - Reserpine
      - Verapamil
    - GI
      - Domperidone
      - H₂ blockers
      - Metoclopramide
      - Proton pump inhibitors (5)[C]
    - Herbal
      - Anise
      - Barley
      - Blessed thistle
      - Fenugreek seed
      - Fennel
    - Illicit
      - Cocaine
      - Marijuana (4)[C]
  - Infectious disease
    - Isoniazid
    - Protease inhibitors
    - Typical and atypical antipsychotics
  - Pain
    - Opioids
  - Psych/neuro
    - Neuroleptics
    - Stimulants
    - Selective serotonin reuptake inhibitors (SSRIs) (prolactin not always elevated)
    - Tricyclic antidepressants
  - Reproductive
- Estrogens
- Copper intrauterine device
  – Postoperative condition, especially oophorectomy
  – Idiopathic
    o Normal prolactin levels

Genetics
No known genetic component

RISK FACTORS
Female. Certain medications and supplements—see below.

GENERAL PREVENTION
- Frequent nipple stimulation can cause galactorrhea.
- Avoid medications that can suppress dopamine.

COMMONLY ASSOCIATED CONDITIONS
See “Etiology and Pathophysiology.”

DIAGNOSIS
- Findings vary with causes.
- Look for signs/symptoms of associated conditions:
  – Acromegaly
  – Adrenal insufficiency
  – Chest wall conditions
  – Hypothyroidism
  – Polycystic ovarian syndrome

HISTORY
- Usually bilateral milky nipple discharge; may be spontaneous or induced by stimulation
- Determine possibility of pregnancy or recent discontinuation of lactation
- Temporal association with initiation of new medication or supplementation
- Signs of hypogonadism from hyperprolactinemia
  – Oligomenorrhea, amenorrhea
  – Inadequate luteal phase, anovulation, infertility
  – Decreased libido (especially in affected males)
- Mass effects from pituitary enlargement
  – Headache, cranial neuropathies
  – Bitemporal hemianopsia, amaurosis, scotomata

PHYSICAL EXAM
Breast examination should be performed with attention to the presence of spontaneous or induced nipple discharge.

DIFFERENTIAL DIAGNOSIS
- Pregnancy-induced lactation or recent weaning (average duration of lactation after weaning is 40 days, but can be longer in cases of prolonged duration of breastfeeding)
Nonmilky nipple discharge
  – Intraductal papilloma
  – Fibrocystic disease
  – Physiologic (nonmilky) discharge: straw-colored, gray, yellow, green, brown

Purulent breast discharge
  – Mastitis
  – Breast abscess
  – Impetigo
  – Eczema

Bloody breast discharge: Consider malignancy (Paget disease, breast cancer)

**DIAGNOSTIC TESTS & INTERPRETATION**
Perform formal visual field testing if pituitary adenoma suspected.

**Initial Tests (lab, imaging)**
- Prolactin level, thyroid-stimulating hormone, pregnancy test, liver and renal functions
- Situations that may alter lab results:
  - Lab evaluation of prolactin may be falsely elevated by a recent breast examination
  - Vigorous exercise
  - Sexual activity
  - High-carbohydrate diet
  - Consider repeating the test under different circumstances if the value is borderline (30 to 40 ng/ml) elevated

  Prolactin levels may fluctuate (tend to be highest in the early morning). Elevated prolactin levels should be confirmed with at least one additional level drawn in a fasting, nonexercised state, with no breast stimulation (6)[C].

  If a breast mass is palpated in the setting of nipple discharge, evaluation of that mass is indicated with mammogram and/or ultrasound.
  - Consideration for sterile culture of nipple discharge (especially if mastitis/abscess is in the differential).

- Pituitary MRI with gadolinium enhancement if the serum prolactin level is significantly elevated (>200 ng/mL) or if a pituitary tumor is otherwise suspected.

**Follow-Up Tests & Special Considerations**
- Consider evaluation of follicle-stimulating hormone and luteinizing hormone if amenorrheic.
- Consider evaluation of growth hormone levels if acromegaly suspected (1)[A].
- Measure adrenal steroids if signs of Cushing disease present.

**Diagnostic Procedures/Other**
If diagnosis is in question, confirm by microscopic evaluation that nipple secretions are lipoid.

**Test Interpretation**
Results of testing can help to rule out causes and elucidate true etiology.

**TREATMENT**
- Avoid excess nipple stimulation.
• Idiopathic galactorrhea (normal prolactin levels) does not require treatment.
• Discontinue causative medications, if possible.
• If SSRI is implicated, trial of mirtazapine.
• Medication to lower prolactin levels is the preferred therapy, with surgery or radiotherapy for
  patients not responding to medication.
• Medical prolactin-lowering treatment is preferred except for tumors >10 mm (even if
  asymptomatic), which should be removed to reduce pituitary tumor size or prevent progression
  to avoid neurologic sequelae.
• If microadenoma, watchful waiting can be appropriate because 95% do not enlarge.

GENERAL MEASURES
Stop offending/causative agents. Stop manipulation of breast/nipple tissue.

MEDICATION
• Dopamine agonists work to reduce prolactin levels and shrink tumor size. Therapy is
  suppressive, not curative (6)[C].
• Treatment is discontinued when tumor size has reduced or regressed completely or after
  pregnancy has been achieved.
• Dopamine agonists are Class B in pregnancy and may be resumed if a macroadenoma grows
  significantly (1)[A].
• Cabergoline (Dostinex)
  – Start at 0.25 mg PO twice weekly and increase by 0.25 mg monthly until prolactin levels
    normalize. Usual dose ranges from 0.25 to 1.00 mg PO once or twice weekly.
  – More effective and better tolerated than bromocriptine
  – Check erythrocyte sedimentation rate and creatinine at baseline and then periodically.
  – ECG at baseline and every 6 to 12 months
  – DC after prolactin level normal for 6 months
• Bromocriptine
  – Start at 1.25 mg QHS PO with food and increase every 3 to 7 days by 2.5 mg/day until
    therapeutic response achieved (usually 2.5 to 15.0 mg/day).
  – More expensive and more frequent dosing; however, most providers have experience with
    this effective drug.
  – Long-term treatment can cause woody fibrosis of the pituitary gland.
  – Check creatinine, complete blood count, liver function tests, cardiovascular evaluation;
    pregnancy test every 4 weeks during amenorrhea and after menses restored if period is >3
    days late.
• Contraindications are similar for all and include the following:
  – Uncontrolled hypertension
  – Sensitivity to ergot alkaloids
• Precautions
  – Dopamine antagonists may cause nausea, vomiting, psychosis, or dyskinesia.
• Significant possible interactions
  – H₂ blockers, CYP3A4; weak serotonin effect; hypotensive effect
  – For women with microadenomas who do not wish to become pregnant, oral contraceptives
    may be a treatment option.

First Line
Cabergoline (see above)

**Second Line**
Bromocriptine (see above)

**ISSUES FOR REFERRAL**
Consider involvement of neurologist (if imaging reveals a pituitary mass), endocrinology (if labs indicate need for further testing), breast surgeon (if concomitant concerns for abscess or other breast mass/malignancy), dermatology if there are refractory skin changes or skin biopsy needed.

**ADDITIONAL THERAPIES**
See “Complementary & Alternative Medicine” section below.

**SURGERY/OTHER PROCEDURES**
- **Surgery**
  - Macroadenomas need surgery if (i) medical management does not halt growth, (ii) neurologic symptoms persist, (iii) size >10 mm, or (iv) patient cannot tolerate medications; also considered in young patients with microadenomas to avoid long-term medical therapy
  - Transsphenoidal pituitary resection
  - 50% recurrence after surgery
- **Radiotherapy**
  - Radiation is an alternative tumor therapy for macroadenomas not responsive to other modes of treatment:
    - 20–30% success rate
    - 50% risk of panhypopituitarism after radiation
    - Risk of optic nerve damage, hypopituitarism, neurologic dysfunction, and increased risk for stroke and secondary brain tumors

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Alternative modalities used to cease milk production include: ingestion of peppermint, parsley, and/or sage on a regular basis; topical application of cabbage leaves over all breast tissue, refreshing with new leaves every 10–15 min; there are also some herbal tea preparations to decrease milk production such as “no more milk tea.” All of these would treat symptoms, not causes.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Admission usually not indicated unless severe mastitis/abscess develops. NSAIDs are helpful.

**ONGOING CARE**
See below.

**FOLLOW-UP RECOMMENDATIONS**
- Outpatient care unless pituitary resection required.
- Bromocriptine patients need adequate hydration.
- Dopamine agonist therapy should be discontinued in pregnancy.

**Patient Monitoring**
Varies with cause
Check prolactin levels every 6 weeks until normalized and then every 6 to 12 months.
Monitor visual fields and/or MRI at least yearly until stable for prolactinoma.

**DIET**
No restrictions. As above, may want to make peppermint, parsley, and sage part of diet.

**PATIENT EDUCATION**
- Warn about symptoms of mass enlargement in pituitary.
- Discuss treatment rationale, risks of treating, and expectant management.
- Review that offending medication and relatives of it should be discontinued long term.
- Patient education material available from American Family Physician:
  https://www.aafp.org/afp/2012/0601/p1073-s1.html

**PROGNOSIS**
- Depends on underlying cause.
- Symptoms can recur after discontinuation of a dopamine agonist.
- Surgery can have 50% recurrence.
- Prolactinomas <10 mm can resolve spontaneously.
- Postsurgical hyperprolactinemia is associated with better outcomes in node-negative breast cancer.

**COMPLICATIONS**
- If enlarging pituitary adenoma, risk of permanent visual field loss
- Panhypopituitarism can complicate radiation or surgical therapy.
- Osteoporosis if amenorrhea persists without estrogen replacement
- Hyperprolactinemia does not increase breast cancer risk.

**REFERENCES**

**SEE ALSO**
Hyperprolactinemia
CODES

ICD10
- N64.3 Galactorrhea not associated with childbirth
- N64.52 Nipple discharge

CLINICAL PEARLS
- Galactorrhea is a common disorder, affecting up to 50% of reproductive-age women.
- Common causes include idiopathic, from excess nipple stimulation, dopamine-suppressing medications, or pituitary prolactinoma.
- Most cases may be adequately evaluated by thyroid-stimulating hormone, prolactin, and human chorionic gonadotropin measurement, with additional testing only as suggested by the presence of other symptoms or signs. However, in a woman >30 years old, strong consideration for imaging with mammography to rule out associated malignancy.
- Lab evaluation of prolactin may be falsely elevated due to recent sexual activity, breast examination, exercise, or a high-carbohydrate diet. Repeat any borderline elevation before continuing evaluation or initiating treatment.
- Evaluate prolactin >200 ng/mL (or signs of suspicion for a pituitary macroadenoma) with a gadolinium-enhanced MRI.
GAMING DISORDER, INTERNET

Madhavi Singh, MD ● Lauren Schneekloth, MD

BASICS

DESCRIPTION

- Internet gaming disorder (IGD) is where the “gamers” play compulsively, to the exclusion of other interests resulting in clinically significant impairment or distress.
- For gaming disorder to be diagnosed, the behavior pattern must be of sufficient severity and would be evident for at least 12 months.
- IGD is identified in section III of DSM-5 as a condition warranting more clinical research and experience before it might be considered for inclusion in the main book as a formal disorder.
- On June 18, 2018, WHO recognized gaming disorder as a mental health condition.
- Gaming disorder (digital or video) is included in ICD-11.

EPIDEMIOLOGY

Incidence

- Predominant age—adolescence
- Predominant sex—male

Prevalence

- Median prevalence of 2.0%
- Prevalence rates are highest in Eastern Asian countries and male adolescents aged 12 to 20 years (1).

ETIOLOGY AND PATHOPHYSIOLOGY

- On the molecular level, Internet addiction is characterized by an overall reward deficiency that entails decreased dopaminergic activity (2).
- On the level of neural circuitry, Internet and gaming addiction lead to neuroadaptation and structural changes that occur as a consequence of prolonged increased activity in brain areas associated with addiction (2).
- On a behavioral level, Internet and gaming addicts appear to be constricted with regards to their cognitive functioning in various domains (2).
- IGD shares multiple features with drug addictions, including elevated impulsivity, cognitive inflexibility, and attentional biases.

RISK FACTORS

The following risk factors were found to be significantly associated with IGD (3):

- Functional and dysfunctional impulsivity
- Belief self-control
- Anxiety
- Pursuit of desired appetitive goals
- Money spent on gaming
- Weekday game time
- Offline community meeting attendance
- Game community membership
Gaming motives play a role as well.
Gamers with psychiatric distress use it as a coping strategy to improve their mood and/or attain emotional stability.
Achievement-related motives may be related to the lack of real-life achievements that are compensated by virtual victories and successes.

COMMONLY ASSOCIATED CONDITIONS
- Anxiety disorder
- Mood disorder
- Autism spectrum disorder
- Attention deficit hyperactivity disorder
- Personality disorder
- Behavioral disorder

DIAGNOSIS

HISTORY
- Thorough history
- DSM-5 section III proposed symptoms of IGD include:
  - Preoccupation with gaming
  - Withdrawal symptoms when gaming is taken away or not possible (sadness, anxiety, irritability)
  - Tolerance, the need to spend more time gaming to satisfy the urge
  - Inability to reduce playing, unsuccessful attempts to quit gaming
  - Giving up other activities, loss of interest in previously enjoyed activities due to gaming
  - Continuing to game despite problems
  - Deceiving family members or others about the amount of time spent on gaming
  - The use of gaming to relieve negative moods, such as guilt or hopelessness
  - Risk, having jeopardized or lost a job or relationship due to gaming
  - Under the proposed criteria, a diagnosis of IGD would require experiencing five or more of these symptoms within a year.
  - The condition can include gaming on the Internet or on any electronic device.
  - Most people who develop clinically significant gaming problems play primarily on the Internet.
  - 7-item Game Addiction Scale—GAS items such as relapse, conflict, withdrawal, and problems (loss of interests) were endorsed more frequently in more severe IGD stages, whereas items related to tolerance, salience (preoccupation), and mood modification (escape) were endorsed more widely among participants (including in less severe IGD stages) (4)

PHYSICAL EXAM
Mental status exam

DIFFERENTIAL DIAGNOSIS
- High-engagement Internet gaming, which is normal
- Social anxiety
TREATMENT

GENERAL MEASURES
- Cognitive-behavioral therapy (CBT) is considered efficacious (5)[A].
- Suggested psychotherapies (6)[C]:
  - CBT is suggested to improve inhibitory control ability, recognize maladaptive cognition, and employ adaptive decision making.
  - Cognitive enhancement therapy to help improve elevated impulsivity, impaired cognitive control, and cognitive inflexibility
  - Cognitive bias modification to target attention biases
  - Mindfulness-based stress reduction to address stress-induced association of IGD

MEDICATION
Methylphenidate, bupropion, and escitalopram have been studied but showed no added benefit.

ONGOING CARE

PATIENT EDUCATION
- American Academy of Pediatrics recommends no screen time for toddlers <18 months of age except video chatting.
- For children 2 to 5 years, limit are for 1 hr/day for high-quality content and parents should co-view.
- For children 6 years and older, should have consistent limits on screen time with designated media-free times
- For all ages, media should not be located in bedroom and video game play should not begin within half an hour before sleep.

PROGNOSIS
Fair

COMPPLICATIONS
- Higher risk of mood disturbance, suicide ideation, and suicide planning in heavy gamers involved with screen times of >5 hours a day (1)
- Reduced sleep duration and disrupted sleep patterns
- Auditory hallucinations
- Enuresis
- Encopresis
- Wrist, neck, and elbow pain, tenosynovitis (“nintendinitis”)
- Obesity
- Skin blisters, calluses, sore tendons
- Hand–arm vibration syndrome and peripheral neuropathy

REFERENCES

ADDITIONAL READING

CLINICAL PEARLS
- IGD is considered a mental health disorder where the “gamers” play compulsively, to the exclusion of other interests resulting in clinically significant impairment or distress with symptoms presence of 12 months.
- Should be differentiated from high-engagement Internet gaming, which is normal
- Most prevalent in Southeast Asian countries in young adolescent males
- Gaming disorder (digital or video) is included in ICD-11.
- CBT is considered efficacious treatment.
GASTRITIS
Marie L. Borum, MD, EdD, MPH, MACP, FACP, AGAF ● Jenny Davé, MD, MS

BASICS
DESCRIPTION
● Inflammation of the gastric mucosa
● Can be classified by time course (acute vs. chronic)
  – Acute: Neutrophilic infiltration on histology
  – Chronic: Mixture of mononuclear cells, lymphocytes, macrophages on histology
● Multiple types of gastritis have been described. There is no universally accepted classification for gastritis.
● Subtypes of gastritis include:
  – Erosive gastritis or reactive gastropathy
    o Mucosal injury by a noxious agent (especially nonsteroidal anti-inflammatory drugs [NSAIDs] or alcohol) or vascular congestion and/or mucosal ischemia
    o Damage to the surface epithelium caused by mucosal hypoxia or the direct action of NSAIDs with no associated inflammation
  – Reflux gastritis
    o A reaction to protracted reflux exposure to biliary and pancreatic fluid
    o Typically limited to the prepyloric antrum
  – Hemorrhagic gastritis (stress ulceration)
    o A reaction to hemodynamic disorder (e.g., hypovolemia or hypoxia [shock])
    o Common in intensive care unit (ICU) patients, particularly after severe burns and trauma
    o Seen rarely with certain medications (e.g., dabigatran, an oral thrombin inhibitor
  – Infectious gastritis
    o Acute and/or chronic Helicobacter pylori infection (most common cause of gastritis)
    o Viral infection (reaction to systemic infection)
    o Phlegmonous gastritis
  – Atrophic gastritis
    o Autoimmune versus environmental
    o Frequent in the elderly
    o Primarily from long-standing H. pylori infections
    o Prolonged proton pump inhibitor (PPI) use
    o Major risk factor for gastric cancer
    o Associated with primary (pernicious) anemia

Geriatric Considerations
Persons age >60 years often harbor H. pylori infection.

Pediatric Considerations
Gastritis rarely occurs in infants or children; increases in prevalence with age.

EPIDEMIOLOGY
Predominant age: all adult ages (more common in elderly)
Predominant sex: male = female

Incidence
Accounts for 1.8–2.1 million medical visits each year in the United States

Prevalence
- Gastritis is more prevalent in those >60 years of age
  - Prevalence of 50-60% by age 60
- ~30–35% of U.S. adults are infected with H. pylori
  - Rates of infection are higher in minority groups and immigrants
  - Prevalence also higher in lower socioeconomic status

ETIOLOGY AND PATHOPHYSIOLOGY
- Noxious agents cause a breakdown in the gastric mucosal barrier, exposing epithelium to injury.
- Infection: H. pylori (most common cause), Staphylococcus aureus exotoxins, and viral infections
- Alcohol
- Aspirin and other NSAIDs
- Bile reflux
- Pancreatic enzyme reflux
- Portal hypertensive gastropathy
- Emotional stress
- Hemodynamic instability (hypoxemia)

Genetics
Unknown, but observational studies show that 10% of a given population is never colonized with H. pylori, regardless of exposure. Genetic variations in TLR1 may help explain some of this observed variation in individual risk for H. pylori infection.

RISK FACTORS
- Age >60 years
- Exposure to potentially noxious drugs or chemicals (e.g., alcohol or NSAIDs)
- Hypovolemia, hypoxia (shock), burns, head injury, complicated postoperative course
- Autoimmune diseases (thyroid disease and diabetes)
- Family history of H. pylori and/or gastric cancer
- Stress (hypovolemia or hypoxia)
- Tobacco use
- Radiation
- Ischemia
- Pernicious anemia
- Gastric mucosal atrophy

GENERAL PREVENTION
- Avoid injurious drugs or chemical agents including but not limited to alcohol and tobacco.
- Patients with hypovolemia or hypoxia (especially ICU patients) should receive prophylaxis with H₂ receptor antagonists, proton pump inhibitors, prostaglandins, or sucralfate.
Consider testing for H. pylori (and eradicating if present) in patients on long-term NSAID therapy.

COMMONLY ASSOCIATED CONDITIONS
- Gastric or duodenal peptic ulcer
- Primary (pernicious) anemia—atrophic gastritis
- Portal hypertension (HTN), hepatic failure
- Mucosa-associated lymphoid tissue (MALT) lymphoma

DIAGNOSIS

HISTORY
- Epigastric discomfort, often aggravated by eating
- Burning epigastric pain
- Anorexia
- Nausea, with or without vomiting
- Significant bleeding is unusual except in hemorrhagic gastritis.
- Rectal bleeding/melena
- Hiccups
- Belching
- Bloating or abdominal fullness
- Unintentional weight loss

PHYSICAL EXAM
- Vital signs to assess hemodynamic stability
- Abdominal exam often normal
- Mild epigastric tenderness
- May have heme-positive stool
- Examine for stigmata of chronic alcohol abuse
- May have pallor, slowing of capillary refill if patient is anemic

DIFFERENTIAL DIAGNOSIS
- Functional abdominal pain (dyspepsia)
- Peptic ulcer disease
- Viral gastroenteritis
- Gastric cancer (elderly)
- Cholecystitis
- Pancreatic disease (inflammation vs. tumor)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Usually normal
- Complete blood count to evaluate for blood loss/anemia
- Stool analysis for fecal H. pylori antigen
  - 95% specificity and sensitivity
  - Can be used for diagnosis and eradication
- $^{13}$C-urea breath test for H. pylori
– 95% specificity and sensitivity

H. pylori, serology serum IgG
– Inexpensive; 85% sensitivity, 79% specificity
– Positive in history of colonization or prior infections; cannot be used to assess eradication

Gastric acid analysis may be abnormal but is not a reliable indicator of gastritis.

Low serum pepsinogen I (PG I) relative to PG II is associated with fundal intestinal metaplasia.

Patients with autoimmune chronic gastritis may have antibodies to intrinsic factor or parietal cells, with elevated serum fasting gastrin level.

Drugs that may alter lab results: Antibiotics or PPIs may affect urea breath test for H. pylori.
– Hold PPIs for 2 weeks, H₂ receptor antagonists for 24 hours, and antibiotics for 4 weeks prior to stool or breath tests (1)[C].

Follow-Up Tests & Special Considerations

Endoscopy for H. pylori
– Obtain biopsy for culture; polymerase chain reaction (PCR); histology; rapid urease testing

Diagnostic Procedures/Other

Gastroscopy with biopsy is first-line diagnostic tool in:
– Age >50 years with new-onset signs and symptoms (2)
– Weight loss, persistent vomiting, or GI bleed (1)[C]

Gastroscopy with biopsy should also be considered for patients <50 who are H. pylori negative (2)

Gastric biopsies (multiple) in both body and antrum recommended if there is a poor response to initial treatment. Patients must discontinue PPIs for 2 weeks prior to endoscopy to improve diagnostic accuracy.

Test Interpretation

– Acute or chronic inflammatory infiltrate in gastric mucosa, often with distortion or erosion of adjacent epithelium; presence of H. pylori often confirmed. Ulcers or bleeding may be present.
– Biopsies from both the antrum and body of the stomach

TREATMENT

GENERAL MEASURES

– H. pylori treatment is required to relieve symptoms.
– Parenteral fluid and electrolyte supplements if unable to tolerate oral intake
– Discontinue NSAID use if possible.
– Abstinence from alcohol; smoking cessation
– Endoscopy in patients not responsive to treatment

MEDICATION

First Line

– Antacids: best given in liquid form, 30 mL 1 hour after meals and at bedtime; useful mainly as an emollient
– H₂ receptor antagonists (e.g., cimetidine [Tagamet]): oral cimetidine 300 mg q6h (or ranitidine
[Zantac] 150 mg BID or famotidine [Pepcid] 20 mg BID or nizatidine [Axid]); 150 mg BID not shown to be clearly superior to antacids

- Sucralfate (Carafate): 1 g q4–6h on an empty stomach; rationale uncertain but empirically helpful
- Prostaglandins (misoprostol [Cytotec]): can help allay gastric mucosal injury; dosage 100 to 200 μg QID
- PPIs if no response to antacids or H₂ receptor blockers (e.g., omeprazole 20 mg daily or BID or esomeprazole 20 mg daily or BID)

- H. pylori eradication
  - Clarithromycin triple therapy (CTT)
    - A short-course therapy (10 to 14 days) of amoxicillin 1 g BID, standard dose PPI BID (omeprazole 20 mg BID, etc.), and clarithromycin 500 mg BID (3)[A]
    - 70–85% eradication
    - Optional treatment still undefined
    - If PCN allergic: Substitute amoxicillin with metronidazole 500 mg TID.
  - Bismuth quadruple therapy (BQT)
    - PPI (omeprazole 20 mg) BID plus bismuth (Pepto-Bismol) 30 mL liquid or 2 tablets QID plus metronidazole 250 mg QID plus tetracycline 500 mg QID for 10 to 14 days (3)[A]
    - 75–90% eradication
    - Use as initial therapy in areas of high clarithromycin resistance (>15%).
    - Consider in penicillin-allergic patients.

- Alternative H. pylori treatment: sequential antibiotic therapy with standard dose PPI (i.e., omeprazole 20 mg) and amoxicillin 1 g BID for 5 days followed by clarithromycin 500 mg and tinidazole mg BID with standard-dose PPI (omeprazole 20 mg) BID for 5 days; equivalent to triple therapy (1)[B],(3)[A]

- H. pylori treatment failure: Use a different regimen; avoid clarithromycin (unless resistance testing confirms susceptibility):
  - BQT for 7 to 14 days (1,3)[A]
  - Consider levofloxacin 250 mg BID, amoxicillin 1 g BID, and standard-dose PPI BID for 14 days in those who fail twice (1,3)[A].
  - In those allergic to penicillin, consider levofloxacin quadruple therapy with levofloxacin 250 mg QD, omeprazole QD 40 mg, nitazoxanide 500 mg BID, and doxycycline 100 mg QD for 7–10 days (4)[B].

- Consider probiotics in known symptomatic H. pylori. May decrease density of H. pylori in gastric antrum and body; decrease severity of gastritis, peptic ulcers; and possibly slow progression toward atrophic gastritis and gastric adenocarcinoma (5)[C]
  - Probiotics alone likely do not eradicate H. pylori.
  - Possible regimens as used in trials: Bifidobacterium infantis BID × 14 days

- Contraindications: hypersensitivity
- Precautions:
  - Bismuth may turn stool black.
- The manufacturer’s profile of each drug lists precautions and potential drug interactions.

**SURGERY/OTHER PROCEDURES**

Surgical intervention is not necessary, except in the case of phlegmonous gastritis or gastritis with high-grade dysplasia.
COMPLEMENTARY & ALTERNATIVE MEDICINE
Some studies suggest cranberry may inhibit the growth of H. pylori.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Prophylaxis in ICU patients
- Outpatient management, except for severe hemorrhagic gastritis

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Usually no restrictions
- Confirm H. pylori eradication 4+ weeks after treatment.

Patient Monitoring
- Consider repeat endoscopy after 6 weeks if gastritis was severe or if poor treatment response.
- Surveillance endoscopy every 3 to 5 years in patients with atrophic gastritis in both the antrum and body, within 1 year for patients with low-grade dysplasia (with extensive biopsy sampling), endoscopy at 6 and 12 months for patients with high-grade dysplasia
- 25% of patients with high-grade dysplasia may progress to adenocarcinoma within a year
- It is recommended patients with confirmed high-grade dysplasia undergo surgical or endoscopic resection (6)[C]
- Surveillance may be suspended when two or more endoscopies are negative for dysplasia (6) [C]

DIET
Diet restrictions (e.g., bland, light, soft foods) depend on symptom severity. In general, avoid caffeine, spicy foods, and alcohol.

PATIENT EDUCATION
- Smoking cessation; limit alcohol.
- Dietary changes
- Relaxation therapy
- Avoid NSAIDs if possible.

PROGNOSIS
- Most cases clear with identification and treatment of the underlying cause.
- One exception is phlegmonous gastritis, which has a 65% mortality even with treatment.
- Recurrence of H. pylori infection requires a repeated course of treatment.

COMPLICATIONS
- Bleeding from extensive mucosal erosion or ulceration
- Gastric outlet obstruction due to edema limiting adequate transfer of food from stomach to small intestine.
- Presence of H. pylori may lead to gastric intestinal metaplasia, which puts patient at a 10-fold increase of developing gastric cancer
- Clearing H. pylori before the development of chronic gastritis may prevent development of gastric cancer.
Chronic autoimmune gastritis has increased risk for development of gastric neuroendocrine tumors and adenocarcinoma due to dysplasia

REFERENCES

ADDITIONAL READING

CODES

ICD10
- K29.70 Gastritis, unspecified, without bleeding
- K29.71 Gastritis, unspecified, with bleeding
- K29.00 Acute gastritis without bleeding

CLINICAL PEARLS

- H. pylori is the most common cause of gastritis.
- >50% of adult patients are colonized with H. pylori by age 60 years.
- H. pylori antibodies decline in the year after treatment and should not be used to determine
eradication.

- H. pylori stool antigen tests can be used before and after therapy to assess for eradication and reinfection.
- Several courses of therapy may be necessary to eradicate H. pylori.
- In cases of suspected gastritis, discontinue PPI 2 weeks prior to endoscopy to improve diagnostic accuracy.
- Consider probiotics as adjunct treatment in symptomatic H. pylori gastritis.
GASTROESOPHAGEAL REFLUX DISEASE
Adriana S. Sanchez, MD • Fozia Akhtar Ali, MD

BASICS

DESCRIPTION
- Changes of the esophageal mucosa resulting from reflux of gastric contents into the esophagus
- Often described as “heartburn,” “acid indigestion,” and “acid reflux”

EPIDEMIOLOGY

Incidence
Incidence: 5/1,000 person-years

Prevalence
- 10–20% in the United States
- 40% of adults in the United States have reflux symptoms.
- 50–85% of gastroesophageal reflux disease (GERD) patients have nonerosive reflux disease.
- Chronic GERD is a risk factor for Barrett esophagus.
- 10% of patients with chronic GERD have Barrett esophagus.
- Risk of adenocarcinoma without Barrett esophagus and no dysplasia: 0.1–0.5% per patient-year
- Risk of adenocarcinoma with Barrett esophagus and high-grade dysplasia: 6–19% per patient-year
- Pediatric population: Regurgitation occurs at least once a day in 2/3 of 4-month-old infants, decreasing to 21% at age 6 to 7 months, and 5% at 10 to 12 months.

ETIOLOGY AND PATHOPHYSIOLOGY
- The pattern and mechanism of reflux varies depending on the severity of disease.
- GERD begins when acidic stomach contents contact the squamous mucosal lining of the esophagus, at the esophagogastric junction (EGJ).
- Inappropriate transient lower esophageal sphincter (LES) relaxation. Foods that are spicy; acidic; and high in fat, caffeine, alcohol, tobacco, anticholinergic medications, nitrates, smooth muscle relaxants affect LES relaxation.
- Patients with severe GERD often have evidence of a hiatal hernia, which can:
  - Trap acid in the hernia sac
  - Impair acid emptying
  - Increase retrograde acid flow rate
  - Reduce the EGJ sphincter pressure
  - Increase frequency of transient LES relaxations

Genetics
Genetic heterogeneity has been associated with GERD.

RISK FACTORS
- Obesity
- Hiatal hernia
Scleroderma
Alcohol use
Tobacco use
Pregnancy

**GENERAL PREVENTION**
- Decrease consumption of food and beverage triggers such as spicy, fatty foods, alcohol, and caffeine.
- Weight loss
- Avoid lying down after meals.
- Tobacco and alcohol cessation
- Elevate head of bed at night.
- Avoid meals close to bedtime.
- Infants: Use car seat for 2 to 3 hours after meals; thickened feedings

**COMMONLY ASSOCIATED CONDITIONS**
- Nonerosive esophagitis
- Erosive esophagitis
- Irritable bowel syndrome
- Peptic ulcer disease
- Extraesophageal reflux: aspiration, chronic cough, laryngitis, vocal cord granuloma, sinusitis, otitis media
- Halitosis
- Hiatal hernia: acid pocket (zone of high acidity in the proximal stomach above the diaphragm)
- Peptic stricture: 10% of patients with GERD
- Barrett esophagus
- Esophageal adenocarcinoma

**DIAGNOSIS**

**HISTORY**
- Typical symptoms: acid regurgitation, heartburn, dysphagia (mostly postprandial)
- Atypical symptoms: epigastric fullness/pressure/pain, dyspepsia, nausea, bloating, belching, chest pain, lump in throat
- Extraesophageal signs and symptoms: chronic cough, bronchospasm, wheezing, hoarseness, sore throat
- Heartburn: retrosternal burning sensation
- Regurgitation: sour or acid taste in mouth ("water brash")
- Symptoms worse with bending or lying down
- Diet, alcohol and tobacco use

**PHYSICAL EXAM**
Often benign but look for potential:
- Epigastric tenderness or palpable epigastric mass
- Dental erosions
DIFFERENTIAL DIAGNOSIS
- Infectious esophagitis (Candida, herpes, HIV, cytomegalovirus)
- Chemical esophagitis; pill-induced esophagitis
- Eosinophilic esophagitis
- Nonulcer dyspepsia
- Biliary tract disease
- Radiation injury
- Crohn disease
- Angina/coronary artery disease
- Esophageal stricture or anatomic defect (ring, sling)
- Esophageal adenocarcinoma
- Achalasia; scleroderma
- Peptic ulcer disease

DIAGNOSTIC TESTS & INTERPRETATION
Diagnosis typically is based on history and clinical symptoms.

Initial Tests (lab, imaging)
- Indication for laboratory workup depends on clinical presentation. Check for anemia (history of bleeding; or possible poor vitamin B<sub>12</sub> absorption due to chronic proton pump inhibitor [PPI] use).
- Appropriately evaluate patients who present with symptoms suspicious for cardiac disease.

Diagnostic Procedures/Other
Upper endoscopy
- First-line diagnostic test for those with alarm signs and uncontrolled symptoms (1)[B]
- Indications for endoscopy:
  - Alarm symptoms such as dysphagia, bleeding, anemia, weight loss, recurrent vomiting
  - Persistent typical GERD symptoms despite treatment with twice-daily PPI for 4 to 8 weeks
  - Men >50 years with chronic GERD (>5 years) and other risk factors: hiatal hernia, high BMI, tobacco use, high abdominal fat distribution
  - History of severe erosive esophagitis (Assess healing and check for UGI pathology including Barrett esophagus.)
  - Surveillance (history of Barrett esophagus)
- ~50–70% of patients with heartburn have negative endoscopic findings.

Esophageal manometry
- Used to evaluate peristaltic function preoperatively and to record LES pressure
- Not recommended for primary GERD diagnosis; a second option for those with GERD and normal endoscopy (1)[B]
- Diagnose motility disorders: functional heartburn, achalasia, and distal esophageal spasm.

Ambulatory reflux (pH) monitoring
- Evaluate excessive acid exposure in those with GERD symptoms, normal endoscopy, and no response to PPI (1)[B].
- Used to document frequency of reflux
- Discontinue PPI for 7 days prior to procedure.

Barium swallow: not used for GERD diagnosis; used to evaluate complaints of dysphagia or to outline anatomic abnormalities (hiatal hernia)
TREATMENT

GENERAL MEASURES
Lifestyle changes are first-line intervention:
- Elevate head of bed (1)[B].
- Avoid meals 2 to 3 hours before bedtime (1)[B].
- Avoid stooping, bending, and tight-fitting garments.
- Avoid medications that relax LES (anticholinergic drugs; calcium channel blockers).
- Promote weight loss (1)[B].
- Tobacco cessation and alcohol avoidance
- Limit consumption of patient-specific food triggers (global elimination of all reflux-causing foods is not necessary, practical, or beneficial).

Step wise approach to therapy
- Phase I: lifestyle and diet modifications, antacids plus H₂ blockers or PPIs
- Phase II: If symptoms persist, consider endoscopy.
- Phase III: If symptoms still persist, consider surgery.

MEDICATION
First Line
- H₂ blockers in equipotent oral doses (e.g., ranitidine 150 mg BID, famotidine 20 mg BID
  - Renally dosed: Decrease dose to 50 mg and for creatinine clearance <50 mL/min.
  - Although less effective than PPIs, H₂ blockers given in divided doses provide symptomatic relief in patients with less severe symptoms (2)[A].
- PPIs: irreversibly bind proton pump (H⁺/K⁺ ATPase), effective onset within 4 days; omeprazole 20 to 40 mg/day, pantoprazole 40 mg/day, esomeprazole 40 mg/day, lansoprazole 15 to 30 mg/day, dexlansoprazole 30 mg/day, rabeprazole 20 mg/day
  - No major differences in efficacy among PPIs
  - Dose 30 to 60 minutes before meals with the exception of dexlansoprazole (1)[A].
  - PPIs may increase risk of hypomagnesemia, hip fracture, Clostridium difficile infection, vitamin B₁₂ deficiency, and community-acquired pneumonia.
- PPI more effective than H₂ blocker and prokinetics for healing erosive and nonerosive esophagitis (3)[A].
- Erosive esophagitis: 8 weeks of PPI effective in 90%
- Reevaluate symptoms after 4–8 weeks of treatment.

Pediatric Considerations
Antacids or liquid H₂ blockers and PPIs are available. Prokinetics have a minimal role due to safety concerns and limited efficacy.

Second Line
- Antacids or barrier agents (sucralfate 1 g PO QID 1 hour before meals and at bedtime for 4 to 8 weeks) may relieve breakthrough symptoms.
- Prokinetics: metoclopramide 5 to 10 mg before meals
- Precautions
  - Blood dyscrasias and anemia with PPIs and H₂ blockers
– Metoclopramide is a dopamine blocker; risk of dystonia and tardive dyskinesia
– Tachyphylaxis may occur with H₂ blockers.

**Significant possible interactions**
– PPIs and H₂ blockers: multiple cytochrome P450 drug interactions; warfarin, phenytoin, antifungals, digoxin

**ISSUES FOR REFERRAL**
Persistent or severe disease

**SURGERY/OTHER PROCEDURES**
– Laparoscopic fundoplication (wrapping gastric fundus around distal esophagus) increases pressure gradient between stomach and esophagus.
– Bariatric surgery
  – Surgery indicated if patient desires to discontinue medical therapy, has side effects with medical therapy, has a large hiatal hernia, has esophagitis refractory to medical therapy, or has refractory symptoms. Gastric bypass is preferred (3)[A].
  – Manometry to rule out esophageal dysmotility, achalasia, or scleroderma prior to surgery (3)[A]

**Pediatric Considerations**
Surgery for severe symptoms (apnea, choking, persistent vomiting)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
– Monitor symptoms over time. Consider additional workup and/or treatment if symptoms fail to improve after 8 weeks of PPI treatment.
– Repeat endoscopy in 4 to 8 weeks if there is a poor symptomatic response to medical therapy, especially in older patients.
– In patients with Barrett esophagus who would opt for treatment if cancer is detected, perform endoscopic surveillance every 2 to 3 years.

**PATIENT EDUCATION**
Lifestyle and dietary modifications: Eat small meals; avoid lying down after meals; elevate head of bed; weight loss; smoking cessation; avoid alcohol and caffeine.

**PROGNOSIS**
– Symptoms and esophageal inflammation often return promptly when treatment is withdrawn. To prevent relapse of symptoms, continue antisecretory therapy (in addition to lifestyle and dietary modifications).
  – PPI maintenance therapy likely improves quality of life more than H₂ blockers.
  – Full-dose PPIs are more effective than half-dose for maintenance (3)[A].
  – In erosive esophagitis, daily maintenance therapy with PPI prevents relapse; intermittent PPI therapy not as effective
– Medical and surgical therapy are equally effective for symptom reduction (3)[A].
Antireflux surgery
- 90–94% symptom response. Patients with persistent symptoms should have repeat anatomic evaluation (endoscopy or esophagram).
- Some surgically treated patients eventually require medical therapy due to recurrence of symptoms.
Regression of Barrett epithelium does not routinely occur despite aggressive medical or surgical therapy.

COMPLICATIONS
- Peptic stricture: 10–15%
- Barrett esophagus: 10%
  - Adenocarcinoma cancer develops at an annual rate of 0.5%.
  - Primary treatment for Barrett esophagus with high-grade dysplasia is endoscopic radiofrequency ablation.
- Extraesophageal symptoms: hoarseness, aspiration, (including pneumonia)
- Bleeding due to mucosal injury
- Noncardiac chest pain

Geriatric Considerations
Complications more likely (e.g., aspiration, pneumonia)

ADDITIONAL READING

SEE ALSO
Algorithms: Abdominal Pain, Upper; Dyspepsia

CODES
ICD10
- K21.9 Gastro-esophageal reflux disease without esophagitis
• K21.0 Gastro-esophageal reflux disease with esophagitis

**CLINICAL PEARLS**

- GERD is diagnosed primarily by an accurate medical history.
- Consider GERD in nonsmokers with a chronic cough (>3 weeks).
- PPIs provide the most rapid symptomatic relief and healing of esophagitis.
- Consider additional workup and/or treatment if symptoms fail to improve after 8 weeks of PPI treatment.
- Endoscopy is recommended for patients with alarm symptoms, onset age >50 years, or prolonged severe symptoms.
GAY HEALTH
Justin Bowen Neisler, MD  Kimberly Insel, MD, MPH

BADICS

DESCRIPTION

● Health disparities exist among sexual minority groups (gay or lesbian and bisexual) and between sexual minority groups and heterosexuals; disparities are far reaching and include differences in health conditions, health behaviors, health care access, and health care utilization. Sexual minority groups tend to fare worse across all realms.

● LGBT individuals may hide their orientation out of fear of stigma and discrimination, so it is important to ask all patients about sexual identity and behavior in a nonjudgmental environment.

● Structural barriers of a heterosexist and unwelcoming healthcare system and the minority stress (fear, stigma, internalized homophobia) experienced by LGBT people likely contribute to the development of health disparities. These disparities do not arise from innate characteristics of LGBT people.

● This chapter focuses on the diverse group of gay, bisexual, and other men who have sex with men (MSM). Although lesbian and transgender health are discussed separately under their respective topic headings, please note that many of the disparities and risks discussed here affect transgender women at similar or higher levels than men. Men who have sex with transgender women may need many of the same screenings and prevention strategies as MSM.

● Although this chapter reviews the important topics that disproportionally affect this population, primary care of MSM is foremost about delivering the same care delivered to all patients.

GENERAL PREVENTION

● All MSM should receive hepatitis A and B immunizations (1)[A].

● Young MSM <26 years old should be vaccinated against HPV (1)[C].

● Centers for Disease Control and Prevention (CDC) recommends at least annual screening for HIV, syphilis, gonorrhea, and chlamydia as detailed below.

● CDC recommends testing for hepatitis B (2)[A].

● Annual screening for hepatitis C is only recommended in MSM with HIV (2)[A].

● Screening for hepatitis A is not recommended.

DIAGNOSIS

● Sexually transmitted infections (STIs)
  – STIs among MSM are increasing. In 2016, MSM accounted for approximately 58% of new cases of primary and secondary syphilis.
  – Behaviors that increase risk of non-HIV STIs also increase risk of HIV acquisition.
  – Physicians should screen for these high-risk behaviors and advocate for safer sex practices nonjudgmentally from a harm reduction perspective.
  – Behavioral risk factors include the following:
    ○ Anonymous sexual encounters
- Multiple active sex partners
- Inconsistent barrier protection (condom) use
- Substance use around and during sex
- Receptive > insertive anal intercourse
  - Among adolescents, those who are unsure about their sexual identity report the highest rates of sexual risk-taking behavior.
- Annual screening of all asymptomatic sexually active MSM should include:
  - Syphilis serology using both nontreponemal and treponemal testing
  - Urine testing with nucleic acid amplification test (NAAT) for Neisseria gonorrhoeae and Chlamydia trachomatis if having insertive intercourse within the last year
  - Rectal swab NAAT for N. gonorrhoeae and C. trachomatis if having anal receptive intercourse within the last year
  - Pharyngeal swab NAAT for N. gonorrhoeae if having oral receptive intercourse within the last year. Pharyngeal swab for C. trachomatis is not recommended (2)[A].
- Screening should be increased to every 3 or 6 months in MSM at higher risk (see above) (2)[A].
- Because of the stigma of male same-sex sexual behavior, many MSM may not volunteer STI symptoms. Providers should ask about sexual behaviors (insertive/receptive, oral/anal) and the corresponding symptoms of STIs, that is, pain with defecation seen in proctitis.

- HIV
  - 82% of new cases of HIV diagnosed in 2016 were among MSM. These disproportionately affected African American and Hispanic/Latino MSM, young MSM aged 13 to 24 years, and transgender women.
  - Up to 44% of MSM may not know their HIV status. This is more likely in men who are not open about their sexual identity and behavior (2).
  - Sexually active MSM should be screened at least annually for HIV (3)[A].
  - Educate patients having anal sex on multimodal risk reduction using condoms (63% reduction for insertive, 72% receptive), preexposure prophylaxis (PrEP, 90% reduction), and postexposure prophylaxis (PEP) in the case of an unsafe sexual encounter.
  - Indications for PrEP
    - HIV negative (confirm with RNA viral load if exposure within last 4 weeks)
    - Sexually active, but not in a monogamous relationship with an HIV-negative partner
    - And at least one of the following:
      - Anal sex without condoms in past 6 months (receptive or insertive)
      - Any STI diagnosed in past 6 months
      - In a sexual relationship with HIV-positive partner
  - The only FDA-approved regimen for PrEP is daily oral single-pill combination tenofovir disoproxil fumarate (TDF) 300 mg and emtricitabine(FTC) 200 mg, which has shown to be safe and effective in reducing the risk of sexual transfer of HIV (4)[A].
  - Additional medications or replacement with other antiretrovirals is not recommended (4)[A].
  - Although TDF alone is approved for other groups, it is not recommended in MSM because it has not been studied in this population (4)[A].
  - Monitor HIV status every 3 months and renal function at least every 6 months.
  - Indications for PEP
    - ≤72 hours after exposure to known HIV-positive partner
- PEP generally involves 28-day course of highly active antiretroviral therapy (HAART) in a three-drug combination:
  - Two nucleoside reverse transcriptase inhibitors (NRTIs) and either a protease inhibitor (PI) or a nonnucleoside reverse transcriptase inhibitor (NNRTI) or integrase inhibitor
  - Selection of medications are based on side effect profiles, patient compliance, and patient convenience.
  - “Preferred” regimens include the following:
    - Efavirenz plus lamivudine or emtricitabine plus zidovudine or tenofovir
    - Lopinavir/ritonavir (Kaletra) plus lamivudine or emtricitabine plus zidovudine
    - Counsel on safer sex and risk reduction for repeated exposures, including immediate transition to PrEP after completing PEP.

- Cancer
  - Annual incidence of anal cancer is 5 times higher in HIV-negative MSM than the general population; increases to between 78 and 168 times higher in HIV-positive MSM
  - Anal carcinoma has been linked to certain high-risk subtypes of HPV, specifically types 16 and 18.
  - Screening for anal dysplasia with anal cytology may be considered for at-risk populations, especially HIV-infected MSM, but further research is needed for appropriate screening intervals (5)[A].
  - HPV vaccine is recommended for all boys age 11 to 12 years and young MSM through age 26 years to reduce the risk of anal cancer (1)[B].

- Substance and tobacco abuse
  - Tobacco use is double in LGBT populations.
    - LGBT people report not feeling mainstream tobacco cessation inventions connect with them.
    - Alcoholism has also been shown to be more prevalent among gay and bisexual men.
    - Many gay and bisexual men may find difficulty seeking aid in faith-based groups such as Alcoholics Anonymous due to the long history of religious discrimination of LGBT people.
    - Methamphetamine use is increased among MSM; some may use it during or around sexual encounters to increase pleasure and performance.
    - Substance abuse treatment programs implementing cognitive behavioral intervention from a harm reduction perspective is beneficial in reducing stimulant use and sexual risk-taking behavior.

- Mental health
  - Most LGBT people, like all people, are mentally healthy; however, risks for developing major depressive, bipolar, and anxiety disorders are 1.5 times higher in the LGBT population (6).
  - Risk of deliberate self-harm is also increased especially among youth due to stressors such as having an identity different than family and peers, isolation, bullying, family rejection, and self-nonacceptance.

**Pediatric Considerations**
- Normalizing nonheterosexual identities and behaviors during regular screening of sexual development during well adolescent visits could reduce stigma and decrease risk for negative mental health outcomes.
- Rates of body image and eating disorders are increased in adolescent and young adult gay
men.

– Depression has been linked to increased sexual risk-taking behavior.
– In addition to depression screenings recommended for all patients, regular assessments of mental health and suicide risk should include questions about family and peer support, experiences of stigma, connection to an LGBT community, and self-acceptance.

● Intimate partner violence (IPV) (domestic violence)
– Recent study reported ~21% of sexual minority men with a history of physical abuse and ~50% with psychological abuse; highest rates reported among bisexual men
– Despite rates of IPV among male same-sex couples being equal to heterosexual couples, there is a lack of attention to IPV among LGBT people.
– Same-sex IPV can be complex, involving worsening of the emotional and psychological minority stress of the victim, threats to “out” partner, abuse regarding HIV status.
– Gay and bisexual victims are less likely to have support from family or the community.
– Providers can stigmatize male same-sex IPV as not being as serious.
– Screen for IPV with patients alone.
– Be prepared to respond with compassion and connection to local LGBT-welcoming resources.

ONGOING CARE

Obtaining a history
● Establish with patients that information related to sexual orientation is confidentially asked of all patients to assist in providing them the best care.
● Avoid labeling patients as gay, lesbian, bisexual, or transgender unless prompted by the patients.
● Intake forms and waiting room and marketing materials inclusive of same-sex couples and identities create a welcoming and open environment.
● Individualize regular discussions about substance and tobacco abuse, HIV/STIs, mental health, and IPV.
● Take an inclusive and complete sexual history:
  – Do you have sex with men, women, both?
  – Who are you having sex with?
  – Do you use drugs or drink alcohol before sex?
  – How do you protect yourself during sex?
  – How often do you use condoms?
  – Do you feel comfortable with your sexuality?
  – Tell me about your support system?
  – Do you have a significant other?
  – Do you feel safe and supported in your relationship?
  – Are you interested in PrEP?

PATIENT EDUCATION
● Educate patients on risk-reduction strategies for safer sex such as avoiding or limiting substance use around sex, condoms, PrEP, and PEP.
Educate patients on LGBT-specific or welcoming resources in your community for substance and tobacco abuse, IPV, mental health, and suicide prevention.

ADDITIONAL READING

**CODES**

**ICD10**
- Z11.59 Encounter for screening for other viral diseases
- Z11.4 Encounter for screening for human immunodeficiency virus
- Z72.52 High risk homosexual behavior

**CLINICAL PEARLS**

- Provide gay, bisexual, and MSM with the same comprehensive primary care delivered to all patients.
- Create a welcoming, open, nonjudgmental, and inclusive environment of care.
- All sexually active MSM should be offered annual screening for HIV, syphilis, rectal and urethral gonorrhea and chlamydia, and pharyngeal gonorrhea.
- Immunize all MSM for hepatitis A and B as well as all young MSM through age 26 years for HPV.
- Counsel patients on risk-reduction strategies for safer sex such as avoiding or limiting substance use around sex, condoms, PrEP, and PEP.
- Regularly screen for substance use, mental health conditions, eating disorders, suicidality, and IPV and be ready to respond with compassion and connection to LGBT-welcoming resources.
GENITO-PELVIC PAIN/PENETRATION DISORDER (VAGINISMUS)
Jeffrey D. Quinlan, MD, FAAFP

BASICS
Genito-pelvic pain/penetration disorder is the name of the conditions formally known as vaginismus and dyspareunia. Vaginismus results from involuntary contraction of the vaginal musculature. Primary vaginismus occurs in women who have never been able to have penetrative intercourse. Women with secondary vaginismus were previously able to have penetrative intercourse but are no longer able to do so.

DESCRIPTION
- Persistent or recurrent difficulties for 6 months or more with at least one of the following:
  - Inability to have vaginal intercourse/penetration on at least 50% of attempts
  - Marked genito-pelvic pain during at least 50% of vaginal intercourse/penetration attempts
  - Marked fear of vaginal intercourse/penetration or of genito-pelvic pain during intercourse/penetration on at least 50% of vaginal intercourse/penetration attempts
  - Marked tensing or tightening of the pelvic floor muscles during attempted vaginal intercourse/penetration on at least 50% of occasions
- The disturbance causes marked distress or interpersonal difficulty.
- Dysfunction is not as a result of:
  - Nonsexual mental disorder
  - Severe relationship stress
  - Other significant stress
  - Substance or medication effect
- Specify if with a general medical condition (e.g., lichen sclerosus, endometriosis) (1).

Pregnancy Considerations
May first present during evaluation for infertility
- Pregnancy can occur in patients with genito-pelvic pain/penetration disorder when ejaculation occurs on the perineum.
- Vaginismus may be an independent risk factor for cesarean delivery.

EPIDEMIOLOGY
Incidence
The incidence of vaginismus is thought to be about 1–17% per year worldwide. In North America, 12–21% of women have genito-pelvic pain of varying etiologies (2).

Prevalence
- True prevalence is unknown due to limited data/reporting.
- Population-based studies report prevalence rates of 0.5–30%.
- Affects women in all age groups
- Approximately 15% of women in North America report recurrent pain during intercourse.

ETIOLOGY AND PATHOPHYSIOLOGY
Most often multifactorial in both primary and secondary vaginismus

- **Primary**
  - Psychological and psychosocial issues
    - Negative messages about sex and sexual relations in upbringing may cause phobic reaction.
    - Poor body image and limited understanding of genital area
    - History of sexual trauma
  - Abnormalities of the hymen
  - History of difficult gynecologic examination
- **Secondary**
  - Often situational
  - Often associated with dyspareunia secondary to:
    - Vaginal infection
    - Inflammatory dermatitis
    - Surgical or postdelivery scarring
    - Endometriosis
    - Inadequate vaginal lubrication
    - Pelvic radiation
    - Estrogen deficiency
  - Conditioned response to pain from physical issues previously listed

**RISK FACTORS**

- Most often idiopathic
- Although the exact role in the condition is unclear, many women report a history of abuse or sexual trauma.
- Often associated with other sexual dysfunctions

**COMMONLY ASSOCIATED CONDITIONS**

- Marital stress, family dysfunction
- Anxiety
- Vulvodynia/vestibulodynia

**DIAGNOSIS**

DSM-5 has combined vaginismus and dyspareunia in a condition called genito-pelvic pain/penetration disorder.

**HISTORY**

- Complete medical history
- Full psychosocial and sexual history, including the following:
  - Onset of symptoms (primary or secondary)
  - If secondary, precipitating events, if any
  - Relationship difficulty/partner violence
  - Inability to allow vaginal entry for different purposes
    - Sexual (penis, digit, object)
    - Hygiene (tampon use)
    - Health care (pelvic examination)
– Infertility
– Traumatic experiences (exam, sexual, etc.)
– Religious beliefs
– Views on sexuality

PHYSICAL EXAM
- Pelvic examination is necessary to exclude structural abnormalities or organic pathology.
- Educating the patient about the examination and giving her control over the progression of the examination is essential because genital/pelvic examination may induce varying degrees of anxiety in patients.
- Referral to a gynecologist, family physician, or other provider specializing in the treatment of sexual disorders may be appropriate.
- Contraction of pelvic floor musculature in anticipation of examination may be seen.
- Lamont classification system aids in the assessment of severity:
  - First degree: perineal and levator spasm relieved with reassurance
  - Second degree: perineal spasm maintained throughout the pelvic exam
  - Third degree: levator spasm and elevation of buttocks
  - Fourth degree: levator and perineal spasm and elevation with adduction and retreat

DIFFERENTIAL DIAGNOSIS
- Vaginal infection
- Vulvodynia/vestibulodynia
- Vulvovaginal atrophy
- Urogenital structural abnormalities
- Interstitial cystitis
- Endometriosis

DIAGNOSTIC TESTS & INTERPRETATION
No laboratory tests indicated unless signs of vaginal infection are noted on examination. When diagnosing of this disorder has been conducted, five factors should be considered.
- Partner factors
- Relationship factors
- Individual vulnerability factors
- Cultural/religious factors
- Medical factors

Test Interpretation
Not available; may be needed to check for secondary causes

TREATMENT
- Genito-pelvic pain/penetration disorder may be successfully treated (2)[B].
- Outpatient care is appropriate.
- Treatment of physical conditions, if present, is first line (see “Secondary” under “Etiology and Pathophysiology”).
- Role for pelvic floor physical therapy and myofascial release
- Some evidence suggests that cognitive-behavioral therapy may be effective, including
desensitization techniques, such as gradual exposure, aimed at decreasing avoidance behavior and fear of vaginal penetration (3)[A].

- Based on a Cochrane review, a clinically relevant effect of systematic desensitization cannot be ruled out (4)[A].
- Evidence suggests that sex therapy may be effective (4)[B].
  - Involves Kegel exercises to increase control over perineal muscles
  - Stepwise vaginal desensitization exercises
    - With vaginal dilators that the patient inserts and controls
    - With woman’s own finger(s) to promote sexual self-awareness
    - Advancement to partner’s fingers with patient’s control
    - Coitus after achieving largest vaginal dilator or three fingers; important to begin with
      sensate-focused exercises/sensual caressing without necessarily a demand for coitus
    - Female superior at first; passive (nonthrusting); female-directed
    - Later, thrusting may be allowed.
- Topical anesthetic or anxiolytic with desensitization exercises may be considered.
- Patient education is an essential component of treatment (see “Patient Education” section).

**MEDICATION**

- Antidepressants and anticonvulsants have been used with limited success. Low-dose tricyclic antidepressant (amitriptyline 10 mg) may be initiated and titrated as tolerated (3)[B].
- Topical anesthetics or anxiolytics may be used in combination with either cognitive-behavioral therapy or desensitization exercises as noted above (4)[B].
- Botulinum neurotoxin type A injections may improve vaginismus in patients who do not respond to standard cognitive behavioral and medical treatment for vaginismus.
  - Dosage: 20, 50, and 100 to 400 U of botulinum toxin type A injected in the levator ani muscle have been shown to improve vaginismus (4)[B].
- Intravaginal botulinum neurotoxin type A injection (100 to 150 U) followed by bupivacaine 0.25% with epinephrine 1:400,000 intravaginal injection (20 to 30 mL) while the patient is anesthetized may facilitate progressive placement of dilators and ultimately resolution of symptoms (5)[B].

**ISSUES FOR REFERRAL**

For diagnosis and treatment recommendations, the following resources may be consulted:

- Obstetrics/gynecology
- Pelvic floor physical therapy
- Psychiatry
- Sex therapy
- Hypnotherapy

**SURGERY/OTHER PROCEDURES**

Contraindicated

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Biofeedback
- Functional electrical stimulation
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Desensitization techniques of gentle, progressive, patient-controlled vaginal dilation

Patient Monitoring
General preventive health care

DIET
No special diet

PATIENT EDUCATION
- Education about pelvic anatomy, nature of vaginal spasms, normal adult sexual function
- Handheld mirror can help the woman to learn visually to tighten and loosen perineal muscles.
- Important to teach the partner that spasms are not under conscious control and are not a reflection on the relationship or a woman’s feelings about her partner
- Instruction in techniques for vaginal dilation
- Resources
  - American College of Obstetricians and Gynecologists (ACOG), 409 12th St., SW, Washington, DC 20024-2188; 800-762-ACOG. http://www.acog.org/

PROGNOSIS
Favorable, with early recognition of the condition and initiation of treatment

SEE ALSO

Dyspareunia; Sexual Dysfunction in Women

CODES

ICD10

- N94.2 Vaginismus
- N94.1 Dyspareunia

CLINICAL PEARLS

- In a patient with suspected genito-pelvic pain/penetration disorder, a complete medical history, including a comprehensive psychosocial and sexual history and a patient-centric, patient-controlled educational pelvic exam should be conducted.
- This condition can be treated effectively.
- Cognitive-behavioral therapy may be effective for the treatment of this condition.
- Botox injection therapy is in the experimental stages but looks promising for the treatment of vaginismus. Bupivacaine and dilation under general anesthesia has also been tried as a treatment for vaginismus.
GERIATRIC CARE: GENERAL PRINCIPLES
Jeremy Golding, MD, FAAFP • Zahra Sheikh, MD

BASICS

DESCRIPTION
The optimal approach to caring for our elderly patient population requires an understanding of the physiology of normal aging as well as unique geriatric considerations for access to care, diagnosis, treatment, and ongoing care. “First do no harm”; many well-intended diagnostic and therapeutic interventions (with efficacy established in younger patients) may not benefit the elder. Geriatric care, more than many other medical specialties, focuses on preserving and improving function and comfort, rather than on life extension.

EPIDEMIOLOGY
The percentage of the U.S. population anticipated to be >65 years by the year 2050 exceeds 20%, and the percentage of those who are >85 years may reach 24%.

ETIOLOGY AND PATHOPHYSIOLOGY

Physiology of aging
- Although patients age ≥65 years are typically considered elderly, there is variability in the rate of decline in organ function associated with aging dependent on genetic, environmental, socioeconomic factors, as well as disease burden.
- The aging process is not pathologic but part of the developmental continuum. However, physiologic changes associated with aging tend to diminish the body’s compensatory reserve and increase susceptibility to disease.
  - Aging increases body fat and decreases total body water and lean body mass. This results in hydrophilic drugs having a smaller apparent volume of distribution. Lipophilic drugs will have an increased volume of distribution and longer half-life.
  - Aging decreases renal elimination of drugs.
  - Declines in lung capacity, oxygen uptake, cardiac output, muscle mass, glomerular filtration rate as well as blood flow to the brain, liver, and kidneys are associated with aging and must be considered in the diagnosis and treatment of elderly patients.

RISK FACTORS
Access to care
- Despite Medicare, persistent barriers to care include: a lack of provider responsiveness to patient concerns, mounting medical bills, and transportation challenges
- Barriers tend to be more prevalent in the female population and with increasing age.
- Alternatives to the traditional face-to-face visit should be considered to enhance access to care:
  - Encrypted email or home telehealth for those who are technologically equipped
  - Phone visits for those with adequate hearing
  - Nurse visits at home to evaluate and plan care by reporting to provider

GENERAL PREVENTION
- Vaccination schedule for seniors:
  https://www.vaccines.gov/who_and_when/seniors/index.html
Function is the heart of geriatric care. Assess and promote function at each encounter as changes in functional independence are common. Assess: activities of daily living (ADLs), instrumental ADLs (IADLs) (ability to use equipment such as a phone)

- Hearing assessment via hearing
  - Handicapped inventory
- Depression via:
  - Geriatric Depression Scale: https://consultgeri.org/try-this/general-assessment/issue-4.pdf
- Cognition via Mini Cognitive Assessment Instrument:
  https://www.alz.org/media/Documents/mini-cog.pdf and Montreal Cognitive Assessment:
  https://www.mocatest.org/
- Falls: Those with two or more falls in the past year, fall with injury requiring medical treatment, or fear of falling due to difficulty with gait or balance require a full fall risk assessment: https://www.cdc.gov/steadi/pdf/STEADI-Algorithm-508.pdf and https://www.cdc.gov/steadi/materials.html
- Urinary incontinence: Inquire if patient has lost urine >5 times in past year.
- Polypharmacy
  - Use pill bottles, pharmacy records, patient and caregiver input to reconcile medication lists.
  - Ask about use of over-the-counter and alternative medications.
  - Reconcile medications at each visit.
  - Make an attempt to simplify medications at each encounter.
  - Engage patients and their caregivers in discussions regarding prescribing cascade and polypharmacy disadvantages.
- Substance use: CAGE criteria: https://www.mdcalc.com/cage-questions-alcohol-use
- Advanced care planning
  - Completion of an advanced directive among most important interventions
  - Definition: Advanced directives are documents a person completes while still in possession of decisional capacity to ensure their values are reflected when considering how treatment decisions should be made on her or his behalf in the event she or he loses the capacity to make such decisions.
  - Instruments:
    - Durable power of attorney: Patient (called the principal) appoints an agent to handle specific health, legal, and financial responsibilities.
    - Health care proxy: a durable power of attorney specifically for health care decisions; their role is to express the patient’s wishes and make health care decisions if the patient cannot speak for themselves.
    - Living will: a legal document that allows patients to express their wishes for end-of-life medical care, in case they become unable to communicate their decisions
    - Discussions and completion of orders pertaining to end of life care, referred to as POLST (physician order for life-sustaining treatment) in most states and MOLST (medical orders for life-sustaining treatment) in some northeastern states

**DIAGNOSIS**

**HISTORY**

Optimizing communication

- Speak directly to your patient unless directed toward their surrogate.
Assess and manage emotionally charged interactions. Refrain from taking negative energy personally.

Assess patient and caregiver health literacy and adjust explanations accordingly.

Gauge the degree of social and financial support.

Establish patient’s values, preferences, and goals of care.

PHYSICAL EXAM

Geriatric-specific considerations:

- Orthostatic hypotension: contributes to poor energy, diminished functional status, increased risk of falls, and decline in renal function due to ineffective organ perfusion
- Hypothermia/hyperthermia: increased susceptibility in the elderly; less likely to mount a fever in the setting of infection; consider thyroid derangement.
- Weight loss: Assess access to food; may be presenting feature in mood disorder, thyroid derangement, dementia, malignancy
- Hearing: Check for cerumen impaction; perform Whisper Test: https://www.youtube.com/watch?v=PzRzpW6JKzQ

DIFFERENTIAL DIAGNOSIS

Geriatric-specific presentations:

- Coronary artery disease: Elderly patients with coronary heart disease often present with atypical symptoms, including exertional dyspnea. Silent myocardial ischemia is also common.
- Constipation: In older adults, constipation due to slow transit is very common and may be associated with fecal impaction and overflow fecal incontinence.
- Delirium: Nearly 30% of older patients experience delirium at some time during hospitalization.
- Urinary tract infection (UTI): UTI is the most common infectious illness in adults age ≥65 years, but diagnosis of UTI is fraught with difficulty because of the high prevalence of asymptomatic bacteriuria and pyuria, neither of which should be treated unless symptomatic. Asymptomatic bacteriuria is a marker for debility, but treatment does not improve outcomes and may cause harm.
- Depression: It is more common in elderly females. If left untreated, is often the precursor of overt dementia.
- Insomnia: Late-life insomnia is often persistent and may prompt self-medication with over-the-counter sleep aids or alcohol.
- Hearing difficulties: Some studies showed increased incidence of dementia in patient with hearing difficulties.
- Visual Impairment: Macular degeneration, glaucoma, and cataracts are the most commonly encountered causes and a yearly eye exam is important.

DIAGNOSTIC TESTS & INTERPRETATION

Informed decision-making

- Decision-making capacity: Evaluate in four areas: ability to understand information about treatment, ability to appreciate how that information applies to their situation, ability to reason...
Surrogate decision maker
- Patient-identified agent (durable power of attorney for health care, medical power of attorney, health care agent)
- Court-appointed surrogate (legal guardian or conservator)

Diagnostic Procedures/Other
- Avoid unnecessary patient/caregiver burden if results will not significantly enhance the plan of care. Consider risks/harms, cost, time, travel, pain/discomfort, anxiety, and recovery time for all testing under consideration.
- Take into consideration renal function for imaging studies involving contrast.
- Many lab results require comparison with age-specific reference values (e.g., thyroid-stimulating hormone, A1c, prostate-specific antigen, D-dimer)

TREATMENT

GENERAL MEASURES
- Optimize nonpharmacologic options first.
- Align with patients’ goals of care.
- Feasibility for patient and caregivers: Assess cost, availability, travel burden, and adherence
- Compliance
  Nonpharmacologic measures (1): occupational therapy (OT)/physical therapy (PT), speech therapy, hearing aids, walking assist devices, nonpharmacologic treatment of depression and insomnia
- Pharmacologic
  - Start low and go slow.
  - Adjust dose for renal and hepatic function, volume of distribution, decreased protein binding (more free/active drug available)
  - Be cognizant of pill burden, drug–drug interactions, and risks of polypharmacy.
    Anticoagulants and hypoglycemic medication (particularly insulin and sulfonylureas) are high-risk drugs in the elderly.
  - Beers criteria: assists in selecting medications with best geriatric benefit to risk ratio; https://geriatricscareonline.org/ProductAbstract/american-geriatrics-society-updated-beers-criteria-for-potentially-inappropriate-medication-use-in-older-adults/CL001#
- Deprescribing: AGA and Choosing Wisely suggest:
  - Don’t recommend percutaneous feeding tubes in patients with advanced dementia; instead, offer oral-assisted feeding. Feeding tubes do not prolong life and may worsen suffering and thirst in this population.
  - Avoid antipsychotics as the first choice to treat behavioral and psychological symptoms of dementia.
  - Nonpharmacologic interventions are more efficacious than pharmacologic interventions for reducing aggression and agitation in adults with dementia (2)[A]. Antipsychotic medications increase risk of death. They may have a role in a carefully considered overall palliative plan that focuses on nonpharmacologic means of soothing agitation. And in individuals who are being cared for at home and lack of antipsychotics may add caregiver
burden and, hence, hasten placement.

- In diabetes care, meticulously avoid hypoglycemia, which is of far greater potential harm to the patient than is hyperglycemia. Metformin is generally safe. The major goal, especially in care of the older or more debilitated population is maintenance of glucose levels below those that cause symptomatic polyuria and polydipsia. This is not a specific A1c target.
- Don’t use benzodiazepines or other sedative hypnotics in older adults as first choice for insomnia, agitation, or delirium.
- Don’t use antimicrobials to treat bacteriuria in older adults unless specific urinary tract symptoms are present. Delirium in patients seen in the ED and hospital is not likely caused by bacteriuria or lower UTI, but usually by other causes.
- Don’t prescribe cholinesterase inhibitors for dementia without periodic assessment for perceived cognitive benefits and adverse gastrointestinal effects.
- Don’t recommend screening for breast, colorectal, prostate, or lung cancer without considering life expectancy and the risks of testing, overdiagnosis, and overtreatment.
- Avoid using prescription appetite stimulants or high-calorie supplements for treatment of anorexia or cachexia in older adults; instead, optimize social supports, discontinue medications that may interfere with eating, provide appealing food and feeding assistance, and clarify patient goals and expectations.
- Don’t prescribe any medication without conducting a drug regimen review. Consider deprescribing as possible.
- Don’t use physical restraints to manage behavioral symptoms of hospitalized older adults with delirium.

- **Geriatric pain management:**
  - Treatment goal is to improve function.
  - Stepwise care, beginning with nonpharmacologic interventions such as physical therapy, massage, environmental changes (e.g., music and aromatherapy), followed by cautious use of medication as necessary. Nonsteroidal anti-inflammatory medications (NSAIDs) involve significant risks in the elderly (renal, GI, cardiovascular). Use low doses of naproxen or ibuprofen preferentially, with GI-protective medication (e.g., omeprazole) if chronic therapy is needed. Low-dose opioid may be appropriate in some patients. A bowel regimen to prevent obstipation is needed for those using opioids.
  - Pharmacologic: Consider Beers criteria. Many commonly used adjunctive pain medications (e.g., gabapentin) offer little benefit and significant potential for harm in the elderly.
  - Assess the home environment: consider social work consultation, PT/OT evaluations as indicated, and diagnose and address social isolation (3). Home visitation, social activity, and group support may be of particular value. Consider adult day program enrollment.

**MEDICATION**

Nonpharmacologic pain management with modalities like weight reduction, physical therapy, and massage therapy should be tried before medications.

**First Line**

Acetaminophen is the safest when used in <3 g dose over 24 hours.

**Second Line**

Tramadol and other narcotics are preferred over NSAIDs for long-term use. CBD is now gaining popularity among the geriatric population also. Limited studies are available on safety in this age.
group, though.

**ISSUES FOR REFERRAL**
Hard to treat pain, fear of drug dependence

**ADDITIONAL THERAPIES**
Acupuncture, chiropractor

**SURGERY/OTHER PROCEDURES**
- Does surgery align with goals of care? If so, assess surgical risk (harms versus benefits), explore alternatives thoroughly.
- Preop discharge planning with caregiver input

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Use of CAM is on the rise in geriatric patients.
- Discuss potential risks and limitations.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Inpatient prevention measures: Falls, acute delirium, skin breakdown, pain management, infections

**ONGOING CARE**
Home nursing services and care at home with additional resources should be encouraged and promoted to prevent the above complications.

**FOLLOW-UP RECOMMENDATIONS**
- Realistic expectations
- Carefully review medications, eliminate hospital-prescribed unnecessary medications.

**Patient Monitoring**
Use team members optimally, especially home health care, social work, RN care managers.

**DIET**
A well-balanced diet should be encouraged and caloric intake should be optimal. Weight loss is a bigger risk factor for disease and disability.

**PATIENT EDUCATION**
- Caregiver support: Screening for frustration, depression, social supports, financial burden, coping mechanisms, and need for help
  - Resources for caregivers:
    - Local agency on aging (Councils on Aging)
    - Respite care: It is important for caregivers to seek occasional respite from their responsibilities.
    - Support group: Alzheimer’s Association 800-272-3900
- Elder mistreatment, be aware of warning signs such as bruises and lacerations, fractures, malnutrition, and dehydration. Can also screen using:
  - Brief Abuse Screen for the Elderly (BASE)
  - Elder Assessment Instrument (EAI): pressure ulcers, signs of sexual abuse, change in the
ability to manage and control finances (be alert for signs of financial exploitation)

- Interventions:
  - Prevention by supporting caregivers
  - Documentation
  - Reporting to adult protective or other agency
  - Social and medical interventions

- Consider referral for palliative care evaluation
  - A philosophy of care for those with serious illnesses that focuses on symptom, pain, and stress relief with a goal of optimizing functional status and quality of life
  - Ideal for patients with: complex/refractory symptoms, pain, or stress, frequent admissions, complex care needs, decline in function or quality of life

- Consider referral for hospice, a model of end-of-life care that provides physical, emotional, and spiritual support to patients with <6 months life expectancy to maintain optimal quality of life and die with dignity.

REFERENCES

CODES

ICD10
Z71.89 Other specified counseling

CLINICAL PEARLS

- Establish patient goals of care and align all clinical decisions within the context of these goals.
- Use an interdisciplinary team approach to optimize holistic care for elders and their caregivers.
GIARDIASIS
Carol H. Hungerford, DO

BASICS

DESCRIPTION
- Intestinal infection caused by the protozoan parasite Giardia lamblia:
  - G. lamblia is also called Giardia duodenalis and Giardia intestinalis.
- Life cycle consists of cyst and trophozoite stages. Infection results from ingestion of cysts, which transform into trophozoites and colonize the small intestine to cause symptoms. Cysts can maintain viability for several months in cold water sources.
  - The infectious cycle is continued when trophozoites encyst in the large intestine to be subsequently transmitted through water, food, or hands contaminated by feces of an infected person.
- Most infections result from fecal–oral transmission or ingestion of unfiltered surface water (e.g., contaminated swimming areas).
- Less commonly acquired through contaminated food

EPIDEMIOLOGY
- Predominant age:
  - All ages but most common in early childhood (ages 1 to 9 years) and adults 35 to 44 years
- Predominant gender:
  - Male > female (slightly)
- Minimal seasonal variability; slight increase in summer and early fall, July through October
- Over 1 million estimated Giardia-related illnesses annually in the U.S.

Pediatric Considerations
- Most common in early childhood
- Chronic infection in children can lead to intestinal malabsorption (may also be associated with growth restriction).

Prevalence
- 10% of cases of traveler’s diarrhea are caused by parasites, most commonly Giardia (1).
- >19,000 cases per year from U.S. states where Giardia is reportable:
  - Giardia is currently not reportable in Indiana, Kentucky, Mississippi, North Carolina, and Texas.

ETIOLOGY AND PATHOPHYSIOLOGY
Giardia trophozoites colonize the surface of the proximal small intestine: The mechanism of diarrhea is unknown.

Genetics
No known genetic risk factors

RISK FACTORS
- Childcare centers
- Anal intercourse
Wilderness camping  
Travel to developing countries  
Children adopted from developing countries  
Public swimming pools  
Pets with Giardia infection/diarrhea

GENERAL PREVENTION
- Hand hygiene
- Water purification when camping and when traveling to developing countries. Boiling is most effective.
- Properly cook all foods.
- Protect public water supply from fecal contamination.
- Sanitary disposal of feces.

COMMONLY ASSOCIATED CONDITIONS
Hypogammaglobulinemia, IgA deficiency, and immunosuppression are associated with prolonged course of the disease and treatment failures.

DIAGNOSIS

HISTORY
- 25–50% of infected persons are symptomatic.
- Symptoms usually appear 1 to 2 weeks after exposure.
- Persistent diarrhea, often >3 weeks (95%)
- Abdominal cramps (70%)
- Nausea (60%)
- Bloating (50%)
- Flatulence (50%)
- Weight loss (50%), up to 10–20% of ideal body weight
- Malodorous stools
- Anorexia
- Fever (20%), usually early on. If persistent, consider another diagnosis.

PHYSICAL EXAM
- Vital signs are typically normal.
- Nonspecific; abdominal exam; may have bloating, tenderness, or increased bowel sounds

DIFFERENTIAL DIAGNOSIS
- Cryptosporidiosis, microsporidiosis, strongyloidiasis, cyclosporiasis
- Other causes of malabsorption include celiac sprue, tropical sprue, bacterial overgrowth syndromes, and Crohn’s disease.
- Irritable bowel syndrome (diarrhea without weight loss)

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Light microscopy of stool for ova and parasites:
  - Repeat 3 times on separate days.
– Cysts in fixed or fresh stools and occasionally trophozoites are found in fresh diarrheal stools.
– Test limitations: labor intensive; experienced operator is necessary for interpretation; intermittent shedding means that ova may not be present in stool sample.

Stool antigen ELISA: sensitivity and specificity of 100% and 92% (compared to 50% and 70% with microscopy) (2)[A]

Polymerase chain reaction (PCR) techniques are more sensitive than microscopy but have not been widely adopted due to high cost.

Follow-Up Tests & Special Considerations
String test (entero-test):
• A gelatin capsule on a string is swallowed and left in the duodenum for several hours or overnight. The string is removed and evaluated for presence of trophozoites by microscopy.

Diagnostic Procedures/Other
Esophagogastroduodenoscopy (EGD) with biopsy and sample of small intestinal fluid

Test Interpretation
Intestinal biopsy shows flattened, mild lymphocytic infiltration and trophozoites on the surface.

TREATMENT
Outpatient for mild cases; inpatient if symptoms are severe enough to cause dehydration warranting parenteral fluid replacement.

GENERAL MEASURES
• No treatment required in asymptomatic patients.
• Prophylactic therapy indicated for asymptomatic patients in close contact with pregnant or immunocompromised individuals.
• Fluid replacement is first line for dehydration.

MEDICATION
First Line
• Metronidazole (Flagyl): 250 mg PO TID for 5 to 10 days. Cure rates exceed 85%.
• Tinidazole: 2 g PO single dose (50 mg/kg up to 2 g for children)
• Albendazole: 400 mg/day PO daily for 5 days:
  – Albendazole has comparable effectiveness to metronidazole with fewer side effects (3)[A].
• Precautions:
  – Theoretical risk of carcinogenesis with metronidazole
• Significant possible interactions: occasional disulfiram reaction with metronidazole or tinidazole
• Paromomycin (Humatin): a nonaminoglycoside recommended in pregnancy due to lower risk of teratogenicity in the 1st trimester.

Pregnancy Considerations
• Medications to treat giardiasis are relatively contraindicated during pregnancy.
• Paromomycin can be used, but if symptoms are mild delay treatment until postpartum.
**Pediatric Considerations**

Limited evidence to suggest vitamin A reduces prevalence of G. lambila \((4)[A]\).

**Second Line**

- Nitazoxanide suspension approved for treatment of giardiasis in children age 1 to 11 years; children age 1 to 4 years 100 mg BID and age 5 to 11 years 200 mg BID for 3 days.
- Treat failures with a longer course of original agent or change to a different class.
- Multiple combination therapies have been investigated; there are no definitive guidelines for use \((5)[C]\).

**ADDITIONAL THERAPIES**

Anecdotal reports of Mentha crispa for the treatment of Giardia (efficacy is unclear).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Monitor symptoms, weight, and stool exams, particularly if patients fail to improve.

**DIET**

Low lactose/lactose free for at least 1 month; low-fat diet generally helpful.

**PATIENT EDUCATION**

- Hand washing is more important than water purification to prevent transmission in outdoor enthusiasts.
- Lactose intolerance may follow Giardia infection and cause persistent diarrhea posttreatment. Recommend patients adhere to a low-lactose/lactose-free diet to mitigate symptoms.
- CDC facts about Giardia and swimming pools:
  - Don’t swim if you have diarrhea.
  - Wash hands with soap after changing diapers before returning to the pool.
  - Do not ingest pool, lake, or river water.
  - Use chlorine to kill Giardia in water used for recreational activities.

**PROGNOSIS**

- Untreated giardiasis lasts for several weeks.
- Most (90%) patients respond to treatment within a few days:
  - Most nonresponders or relapses respond to a second course with the same or a different agent.

**COMPLICATIONS**

Malabsorption, weight loss, postinfectious IBS, and lactose intolerance.

**ALERT**

Reportable disease to the CDC.

Algorithm: Diarrhea, Chronic

CODES

ICD10
A07.1 Giardiasis [lambliasis]

CLINICAL PEARLS

- Daycare facilities and public swimming pools are common sources of Giardia transmission (a
history of camping or recent travel is not required for the diagnosis).

- Abdominal bloating and loose, foul-smelling stool are common presenting symptoms.
- Metronidazole is highly effective for the treatment of giardiasis (and is often poorly tolerated).
- Most treatment failures respond to a second course of antibiotics (with same or other medication).
- A single fluorescence antibody (FA) or ELISA is as sensitive as three stool samples (looking for ova and parasites) to detect Giardia.
GILBERT SYNDROME
Alethea Y. Turner, DO ● Anna James, DO

BASICS

DESCRIPTION
A benign, inherited syndrome, in which mild, intermittent unconjugated hyperbilirubinemia occurs in the absence of hemolysis or liver dysfunction

Pediatric Considerations
Rare for the disorder to be diagnosed before puberty

Pregnancy Considerations
The relative fasting that may occur with morning sickness can elevate bilirubin level.

EPIDEMIOLOGY
- Predominant age: present from birth but most often presents in the 2nd or 3rd decade of life
- Predominant sex: male > female (2 to 7:1)

Prevalence
Prevalence in the United States: ~8% of the population; ~1 in 3 of those affected are not aware that they have the disorder.

ETIOLOGY AND PATHOPHYSIOLOGY
Indirect hyperbilirubinemia in Gilbert syndrome (GS) results from impaired hepatic bilirubin clearance (~30% of normal) due to decreased levels of the enzyme uridine diphosphoglucuronate-glucuronosyltransferase (UDPGT). Hepatic bilirubin conjugation (glucuronidation) is thus reduced, although this may not be the only defect.

Genetics
- Inherited defects within the promoter region of the gene that encodes the enzyme UDPGT yields reduced conjugation of bilirubin with glucuronic acid.
- Once considered as an autosomal dominant condition, GS is now thought to be inherited in an autosomal recessive manner.

RISK FACTORS
- Male gender
- Family history; particularly first-degree relatives

COMMONLY ASSOCIATED CONDITIONS
GS is part of a spectrum of hereditary disorders that includes types I and II Crigler-Najjar syndrome (1). However, bilirubin levels in these cases will be >6 mg/dL.

DIAGNOSIS

HISTORY
- A nonpruritic jaundice can occur in the setting of fasting, dehydration, infection, lack of sleep,
physical exertion, or surgery. Other symptoms that may present during an episode of jaundice, including fatigue, are caused by the triggering factor and are not directly a result of GS.

- Some medications may also trigger episodes of jaundice in patients with GS due to abnormal metabolism. These include drugs that inhibit glucuronyl transferase (i.e., gemfibrozil) as well as selective protease inhibitors (i.e., atazanavir and indinavir) (2). There is some evidence that tocilizumab (3), a monoclonal antibody used to treat rheumatoid arthritis, and ribavirin, an antiviral for hepatitis C treatment, may also induce jaundice (4). Note, the aforementioned drugs have not been associated with causing liver toxicity in patients with GS.

**PHYSICAL EXAM**

Occasional mild jaundice precipitated by the aforementioned triggers (fasting, dehydration, infection, lack of sleep, physical exertion, surgery, and some medications). Exam should be devoid of the stigmata of chronic liver disease.

**DIFFERENTIAL DIAGNOSIS**

- Hemolysis
- Ineffective erythropoiesis (megaloblastic anemias, certain porphyrias, thalassemia major, sideroblastic anemia, severe lead poisoning, congenital dyserythropoietic anemias)
- Cirrhosis
- Chronic persistent hepatitis
- Pancreatitis
- Biliary tract disease

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Bilirubin: elevated but <6 mg/dL (103 μmol/L) and usually <3 mg/dL (51 μmol/L) (1)[C], virtually all unconjugated (indirect), with conjugated bilirubin within the normal range and/or <20% of the total bilirubin (2)
- CBC with peripheral smear is normal.
- Reticulocyte count, haptoglobin, and lactate dehydrogenase levels are normal.
- Liver function tests (LFTs) (aspartate aminotransferase [AST], alanine transaminase [ALT], alkaline phosphatase, and γ-glutamyl transpeptidase [GGT]) are normal.
- Direct Coombs test is normal.
- Up to 60% of patients with GS have a clinically insignificant mild hemolysis that frequently can only be detected with sophisticated red cell survival studies (1).
- Drugs that may alter lab results: Bilirubin level may be raised by nicotinic acid and some other medications and lowered by phenobarbital (1).
- Disorders that may alter lab results: Bilirubin levels increase during fasting and may increase during a febrile illness.

**Follow-Up Tests & Special Considerations**

GS should be suspected if unconjugated hyperbilirubinemia persists in the absence of hemolysis or other liver dysfunction. A definitive diagnosis may be reported after 3 to 12 months of follow-up if the exam and diagnostic workup is otherwise normal.

**Diagnostic Procedures/Other**

Confirmatory testing is often unnecessary.

- A 48-hour fast is impractical and nonspecific for GS (2).
Provocation testing with rifampin (5) could be employed if there is significant diagnostic doubt:

- After 12 hours of fasting, an increase of total bilirubin to >1.9 mg/dL 2 hours after an oral dose of rifampin 900 mg distinguishes patients with GS with a sensitivity of 100% and a specificity of 100% (5).

Genetic testing is available in the form of polymerase chain reaction (PCR) or DNA-fragment sequencing for DNA mutations in the UGT1A1 gene.

**ALERT**
A liver biopsy is not usually needed to exclude other diagnoses unless concomitant liver disease is present.

**TREATMENT**

- Outpatient
- Avoid unnecessary testing and procedures.
- Specific treatment is not necessary (1).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Once GS has been confidently diagnosed, no further monitoring is required.

**PATIENT EDUCATION**

- Reassure patients that GS is benign.
- Educate patients on common triggers for jaundice.
- Recommend patients to inform medical providers of their diagnosis.
- Instruct patients to seek medical help if severe or prolonged jaundice occurs because these may be signs of a separate disease process.

**PROGNOSIS**

- GS is benign with an excellent prognosis.
- Patients with GS are able to serve as donors for right lobe of liver for transplantation (6).
- Preliminary evidence suggests that patients with GS may have protective properties against cardiovascular disease, type 2 diabetes mellitus, some cancers such as Hodgkin lymphoma, and all-cause mortality (7).

**COMPLICATIONS**
There are no known complications from GS.

**ALERT**
Caution before using irinotecan in patients with GS. Once metabolized, this colorectal cancer treatment affects the enzyme responsible for GS, significantly increasing risk of toxicity (7).
REFERENCES

CODES

ICD10

- E80.4 Gilbert syndrome
- E80.6 Other disorders of bilirubin metabolism

CLINICAL PEARLS

- GS is a benign, inherited syndrome, in which mild, intermittent unconjugated hyperbilirubinemia causing jaundice occurs with otherwise normal liver function.
- Reduced hepatic bilirubin conjugation (glucuronidation) occurs due to altered UDPGT1A1 gene promotion.
- GS is diagnosed when a mild, persistent or recurrent elevation in unconjugated hyperbilirubinemia persists in the absence of hemolysis or other liver dysfunction.
- Confirmatory tests are not frequently needed, and a liver biopsy is not recommended unless there is serious concern for concomitant liver disease.
- Patient education and reassurance is essential, and unnecessary testing and procedures should be avoided.
GINGIVITIS
Karlynn Sievers, MD  Sheila O. Stille, DMD

BASICS

DESCRIPTION
Gingivitis is a reversible form of inflammation of the gingiva. It is a mild form of periodontal disease. Classification includes the following:
- Plaque induced
- Not plaque induced (bacterial, viral, or fungal; e.g., necrotizing ulcerative gingivitis, Vincent disease [“trench mouth”], denture related)
- Modified by systemic factors (e.g., pregnancy, puberty, HIV, diabetes, smoking, leukemia)
- Modified by medications (calcium channel blockers, antipsychotics, antiepileptics, antirejection medications, hormones)
- Modified by malnutrition (vitamin deficiencies)
- Acute or chronic
- System(s) affected: gastrointestinal; ears, nose, throat; dental
- Synonym(s): mild periodontal disease; gum disease

Geriatric Considerations
More frequent in this age group (due more to additive effects than to increased susceptibility)

Pediatric Considerations
Cases of plaque-induced gingivitis are common in children (most common form of pediatric periodontal disease) and usually require no specific interventions other than improved oral hygiene.

Pregnancy Considerations
- Very common in pregnant women; hormonal effect
- Self-limited

EPIDEMIOLOGY
- Predominant age: children, teenagers, and young adults
- Predominant sex: slightly more males than female
- Prevalence ~50% of children
- ~90% of adolescents and adult population
- ~30–75% of pregnant women
- 42% of adults in United States have periodontal diseases (1).

ETIOLOGY AND PATHOPHYSIOLOGY
Inflammation of the marginal gingiva. This can progress to deeper, destructive inflammation; if involving supporting bone, will be classified as periodontitis, not gingivitis (2)
- Usually noncontagious
- Inadequate plaque removal
- Blood dyscrasias (pregnancy)
- Medication induced (e.g., oral contraceptives, antiepileptics)
• Allergic reactions
• Nutritional deficiencies
• Vasoconstriction (nicotine, methamphetamine)
• Endocrine/hormonal variations
  – Pregnancy, menses, menarche
• Chronic debilitating disease
• Vincent disease, necrotizing ulcerative gingivitis
  – Synergistic infection with fusiform bacillus (Fusobacterium spp.) and spirochete (Borrelia
    vincentii)
• Pathology
  – Acute or chronic inflammation
  – Hyperemic capillaries
  – Polymorphonuclear infiltration
  – Papillary projections in subepithelial tissue
  – Fibroblasts

**Genetics**
Possible genetic link (up to 30% of population); rare condition called hereditary gingival
fibromatosis, where severe gingival hyperplasia covers teeth, associated with hirsutism

**RISK FACTORS**
• Poor dental hygiene/plaque formation
• Pregnancy
• Uncontrolled diabetes mellitus
• Malocclusion or dental crowding
• Smoking
• Mouth breathing
• Xerostomia
• Faulty dental restorations
• HIV-positive; AIDS
• Stress
• Hospitalization
• Vitamin C deficiency; coenzyme Q10 deficiency
• Dental appliances (dentures, braces)
• Eruption of primary or secondary teeth
• Necrotizing ulcerative gingivitis
  – Stress
  – Lack of sleep
  – Malnutrition
  – Viral illness
  – Typically teens and young adults
• Bronchial asthma and other respiratory diseases
• Rheumatoid arthritis
• Epilepsy

**GENERAL PREVENTION**
• Good oral hygiene
– Adults
  o Regular twice-daily brushing with fluoride toothpaste
  o May be increased benefit of using circular oscillating electric brush rather than regular brush or sonic/vibration, although evidence is inconclusive (2,3)
  o Daily “high-quality” flossing (studies show that flossing only helps when it is done correctly) and interdental brushes (2,4)
  o Chlorhexidine with oral hygiene better than other oral rinse agents (2,5)
    ■ Use in acute phase (2).
– Pediatrics
  o Regular twice-daily brushing with fluoride toothpaste under parental supervision until full manual dexterity (~8 years of age)
  o Regular flossing if no spaces between teeth
  o Cleaning by a dentist or hygienist every 6 months or more frequently, as indicated (2)
  o Mouth rinse with essential oils (menthol, thymol, eucalyptol; e.g., Listerine) combined with brushing (2)
    – It had been thought that long-term use of alcohol-based mouth rinse may be associated with an increased risk of oral cancer. A recent systematic review found no evidence (2).

COMMONLY ASSOCIATED CONDITIONS
  ● Periodontitis
  ● Glossitis
  ● Pedunculated growths (pyogenic granulomata)

DIAGNOSIS

HISTORY
  ● Gingival erythema, edema, and bleeding
  ● Gingiva is tender to touch but otherwise painless.
  ● Bleeding of gingiva when brushing, flossing, or eating
  ● Inquire about HIV risk, pregnancy, nutritional deficiencies, diabetes, and other risk factors as indicated (see “Risk Factors”).
  ● Smoking history
  ● Poor oral hygiene, infrequent dental visit history

PHYSICAL EXAM
  ● Normal gums should appear pink, firm, stippled, and scalloped.
  ● Gingivitis—marginal gingiva edematous with blunted papilla (usually painless, except to touch)
  ● Gingiva erythema: bright red or red-purple appearance
  ● Bleeding with manipulation of gingiva
  ● Biofilm of plaque (soft) and calculus (calcified, not easily removed)
  ● Edema of interdental papillae
  ● HIV gingivitis
    – Also called linear gingival erythema
    – Narrow band of bright red inflamed gum surrounding neck of tooth
    – Painful
- Bleeds easily
- Rapid destruction of gingival tissue and can progress to periodontitis with destruction of underlying support tissues (periodontal ligament, supporting alveolar bone)

- Vincent disease/necrotizing ulcerative gingivitis
  - Ulcers
  - Fever
  - Malaise
  - Regional lymphadenopathy
  - Pain
  - Mouth odor

**DIFFERENTIAL DIAGNOSIS**
- Periodontitis (deeper inflammation, causing destruction to connective tissue, ligaments, and alveolar bone)
- Glossitis
- Desquamative gingivitis (painful, persistent, usually middle-aged women)
- Pericoronitis (gum flap traps food and plaque over partially erupted 3rd molar), common in adolescence
- Gingival ulcers (aphthous, herpetic, malignancy, tuberculosis, syphilis)
- Specific forms of gingivitis: See “Description,” including acute necrotizing ulcerative gingivitis (Vincent disease) and HIV gingivitis (linear gingival erythema), adrenal crisis, leukemia

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- No tests usually needed
- Possible smear or culture to identify causative agent (HIV gingivitis includes gram-negative anaerobes, enteric strains, and yeast—Candida.)
- Labs for contributing conditions (HIV, pregnancy, diabetes, nutritional deficiencies)
- Increase in C-reactive protein (5)[A]

**GENERAL MEASURES**
- Stop any contributing medications.
- Remove irritating factors (plaque, calculus, faulty dental restorations, or partial dentures).
- Good oral hygiene (see “General Prevention”)
- Regular dental checkups (for scaling and polishing if plaque and/or tartar are present)
- Smoking cessation
- Warm saline rinses BID
- Special needs patients: use of tray-applied 10% carbamide peroxide gels (5)[A]

**MEDICATION**

**First Line**
- Chlorhexidine rinses or varnishes may be used. (Note: Prolonged use of chlorhexidine can lead to blackening of the tongue and taste alterations/metallic.) (6)[B]
Essential oil mouthwash (EOMW) may be equally effective to chlorhexidine for reduction of gingival inflammation (although EOMW is not as effective for plaque control) (2)[A]. Both chlorhexidine and EOMW rinses are as clinically effective as dental prophylaxis and oral hygiene instruction at 6-month recall (2)[A].

Antibiotics indicated only for acute necrotizing ulcerative gingivitis (Vincent disease)

Antibiotics for necrotizing ulcerative gingivitis:
- Penicillin V: pediatric dose, 25 to 50 mg/kg/day divided q6h; adult dose, 250 to 500 mg q6h, or
- Metronidazole: pediatric dose, 30 mg/kg/day PO/IV divided q6h; maximum 4 g/day; adult dose, 500 mg BID or TID for 10 days or
- Amoxicillin/clavulanic acid: pediatric dose, 30 mg/kg/day PO divided q12h; information: use 125 mg/31.25 mg/5 mL suspension; adult dose, 875 mg/125 mg PO BID for 10 days
- Erythromycin: pediatric dose, 30 to 40 mg/kg/day divided q6h; adult dose, 250 mg q6h
- Clindamycin: penicillin allergy; pediatric dose, 8 to 20 mg/kg/day in 3 to 4 divided doses as hydrochloride; adults, 300 mg q6h (maximum 1.8 g/day)
- Doxycycline: adult dose, 100 mg BID 1st day and then QD for 10 days

Topical corticosteroids
- Triamcinolone 0.1% in Orabase (spray or ointment), applied locally TID, QID
  - Contraindications
    - Allergy to specific medication
- Precautions
  - Erythromycin frequently causes GI issues.

Second Line
- Acetaminophen or ibuprofen for any pain (rare)
- Other antibiotics or antifungal rinses or systemic according to culture or smear
- Decapinol oral rinse (surfactant that acts as a physical barrier, making it harder for bacteria to stick to the polysaccharide pellicle on tooth and mucosal surfaces) to reduce bacteria (not recommended for pregnant women or children <12 years); should be used in conjunction with traditional oral hygiene practices when those practices alone are not enough

ISSUES FOR REFERRAL
- Dental referral for acute gingivitis and routine cleanings and further treatment, as needed
- If gingivitis becomes periodontitis, deep root scaling, root planing, and antibiotics may be indicated.

SURGERY/OTHER PROCEDURES
- Débridement for acute necrotizing gingivitis
- Minor surgery may be necessary to correct tissue overgrowth for gingivitis caused by medicines/hereditary gingival fibromatosis.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Bilberry: potentially helpful in reducing inflammation and stabilizing collagen tissue
- Coenzyme Q10: topically, to restore coenzyme Q10 deficiency
- Replace any other nutritional deficiencies (e.g., vitamin A, B₁₂, C).
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Outpatient
- No restrictions

Patient Monitoring
Until clear; dental follow-up for continued cleanings and secondary prevention

DIET
- Well-balanced diet that includes fruits, vegetables, vitamin C; avoid sugary snacks and drinks, which contribute to plaque formation.
- Soft foods during flare, if significant inflammation/bleeding

PATIENT EDUCATION
- Good oral hygiene, including twice-daily brushing with circular oscillating electric brush, fluoridated toothpaste, and daily flossing; regular dental visits

PROGNOSIS
- Usual course: acute, relapsing, intermittent; chronic
- Prognosis: generally favorable, responds well to appropriate treatment
- Left untreated, may progress to periodontitis (controversial), which is a major cause of tooth loss

COMPLICATIONS
Severe periodontal disease (which is associated with supporting bone loss, tooth loss, heart disease, diabetes, dementia, and preterm birth)

REFERENCES

ADDITIONAL READING

SEE ALSO
- Dental Infection; Glossitis
- Algorithm: Bleeding Gums

CODES
ICD10
- K05.10 Chronic gingivitis, plaque induced
- K05.11 Chronic gingivitis, non-plaque induced
- K05.00 Acute gingivitis, plaque induced

CLINICAL PEARLS
- Gingivitis may be prevented and treated with regular dental cleanings, good oral hygiene, and use of certain mouth rinses including chlorhexidine.
- Untreated, gingivitis may progress to periodontitis, a possible contributor to systemic inflammation and its consequences (e.g., coronary artery disease and uncontrolled diabetes) (7).
- New-onset or difficult-to-treat gingivitis, consider differential of etiology: pregnancy, HIV, diabetes, medications, and vitamin deficiencies.
GLAUCOMA, PRIMARY CLOSED-ANGLE
Richard W. Allinson, MD • Francis Allinson, MD

BASICS
DESCRIPTION
• Glaucoma is a progressive decline in vision that is usually associated with elevated intraocular pressure (IOP) in the eye, which leads to damage of the optic nerve. Angle-closure is a mechanical blockage of the trabecular meshwork (TM) by the peripheral iris.
• In primary angle-closure (PAC), there is an anatomical predisposition with no identifiable secondary pathologic condition.
• In secondary angle-closure, there is an identifiable pathologic cause, such as iris neovascularization or an enlarged cataractous lens.
• Angle-closure can be classified as the following:
  – Primary angle-closure suspect (PACS) is >180 degrees of iridotrabecular contact (ITC), but no evidence of TM or optic nerve damage.
  – PAC is >180 degrees of ITC with peripheral anterior synechiae (PAS) or elevated IOP but with no optic neuropathy.
  – Primary angle-closure glaucoma (PACG) is PAC with glaucomatous optic neuropathy.
  – Acute angle-closure crisis (AACC) is when the angle is occluded with symptomatic high IOP. It is a medical emergency requiring prompt treatment.

Geriatric Considerations
Increased risk with age with history of hyperopia and cataracts.

Pregnancy Considerations
Medications used may cross the placenta and be excreted into breast milk. Majority of IOP-lowering medications are within class C, and the risk of adverse effects to the fetus must be balanced with risk of vision loss in the mother.

EPIDEMIOLOGY
• Older age
• Female sex. PAC is 2 to 4 times more common in women than in men. Women tend to have smaller anterior segments and shorter axial lengths.
• More likely in those of Inuit and East or South Asian descent

Prevalence
The prevalence of PACG in patients older than 40 years varies depending on race and ethnicity. The prevalence is 0.1%–0.2% in blacks, 0.1%–0.6% in whites, 0.3% in the Japanese, 0.4%–1.4% in other East Asians, 2.1%–5.0% in the Inuit. The burden of PACG is greater in Asian countries.

ETIOLOGY AND PATHOPHYSIOLOGY
• PAC happens when iris touches the trabecular meshwork in the anterior chamber angle. ITC causes obstruction of aqueous humor outflow through the trabecular meshwork, which causes elevation in IOP. Prolonged ITC can cause scarring, with formation of PAS.
• Most common underlying mechanism of angle-closure is pupillary blockage of the aqueous
flow from posterior to anterior chamber. This causes increase in pressure in the posterior chamber as compared to the anterior chamber. The buildup of pressure in the posterior chamber leads to anterior bowing of the iris and closing of the angle.

– One of the most important factors in closing the angle in an anatomically predisposed eye is dilation of the pupil. Dilation leading to closure of the angle may occur as a result of a variety of causes including darkness, emotion, and medications that can cause the pupil to dilate. Pupillary block is maximal when the pupil is in the mid-dilated position.

● Plateau iris syndrome is an atypical configuration of the anterior chamber angle that can result in acute or chronic PAC. Angle-closure in plateau iris is most often caused by anteriorly positioned ciliary processes that narrow the anterior chamber recess by pushing the peripheral iris forward. A component of pupillary block is often present.

Genetics
First-degree relatives have a 1–12% increased risk in whites; 6 times greater risk in Chinese patients with positive family history.

RISK FACTORS

● Age >50 years
● Female gender
● Asian or Inuit descent
● Family history of angle-closure
● Shallow anterior chamber
● Hyperopia
● Short axial length
● Thick crystalline lens
● Anterior positioned lens
● Plateau iris
● Drugs that can induce angle-closure by dilating the pupil include:
  – Adrenergic agonists (albuterol, phenylephrine), anticholinergics (oxybutynin, atropine), antihistamines, antidepressants including selective serotonin reuptake inhibitors (SSRIs) and tricyclic antidepressants (TCAs), and cocaine
● Drugs that can induce angle-closure by causing a uveal effusion include:
  – Topiramate and other sulfonamides

GENERAL PREVENTION

● Routine eye exam with gonioscopy for high-risk populations
● Prophylactic laser iridotomy may be considered in patients with PACS for preventing PACG.

COMMONLY ASSOCIATED CONDITIONS

● Cataract
● Hyperopia

DIAGNOSIS

HISTORY

● Patient may be asymptomatic as in PACS or may have acute symptoms as in AACC.
● Acute symptoms commonly include unilateral:
- Severe eye pain
- Blurred vision
- Eye redness
- Halos around lights/objects
- Headache
- Nausea and vomiting

- Patients with PACG can be asymptomatic and have subacute symptoms (intermittent subacute attacks) or compromised peripheral vision.
- Family history of acute angle-closure glaucoma
- Obtain history of prescription, over-the-counter, and herbal medications.

**PHYSICAL EXAM**
Includes, but is not limited to, the following in the undilated eye:
- Visual acuity with refractive error (hyperopic eyes especially in older phakic patients)
- Visual field testing
- Pupil size and reactivity (mid-dilated, asymmetric or oval, minimally reactive, and may have relative afferent pupillary defect)
- Slit-lamp examination demonstrates conjunctival hyperemia (in acute cases), central and peripheral anterior chamber shallowing, corneal edema, iris abnormalities (diffuse and focal iris atrophy, posterior synechiae), lens changes (cataract and glaukomflecken-patchy localized anterior subcapsular lens opacities)
- IOP elevation. During an acute attack, the IOP may be high enough to cause glaucomatous optic nerve damage, ischemic nerve damage, and/or retinal vascular occlusion.

- The Van Herick assessment (VHA) is a noncontact estimate of the angle configuration based on comparison of peripheral anterior chamber depth to peripheral corneal thickness using a thin slit lamp beam of light. Even when performed by experienced ophthalmologists, VHA misses a substantial proportion of angle-closure (1)[B].

- Gonioscopy allows visualization of anatomy of the angle of both eyes. Look for ITC and PAS.
- Anterior segment imaging with ultrasound (US) biomicroscopy and anterior segment optical coherence tomography (AS-OCT) to understand the angle anatomy

**DIFFERENTIAL DIAGNOSIS**
- Secondary angle closure due to iris membranes:
  - Neovascularization of the iris
  - Iridocorneal endothelial (ICE) syndrome
- Secondary pupillary block due to the following:
  - Uveitis with secondary posterior synechiae leading to iris bombe
  - Lens-related disorders, such as ectopia lentis or malpositioned intraocular lenses
- Retinal conditions leading to the forward shift of the lens-iris diaphragm:
  - Uveal effusion

- Topiramate is an oral medication prescribed for the treatment of epilepsy, depression, and headaches. In some patients, this medication may cause a syndrome characterized by acute myopic shift and acute bilateral angle closure. Treatment involves immediate discontinuation of the medication and initiation of medical therapy to lower the IOP. Cycloplegia may deepen the anterior chamber and relieve the attack. Because pupillary block is not an underlying mechanism of this syndrome, a peripheral iridotomy is not indicated.
– Intraocular gas or silicone oil
– Hemorrhagic choroidal detachment
– Intraocular tumors

Malignant glaucoma (also called aqueous misdirection)
– Rare form of glaucoma that usually presents following ocular surgery in patients with a
   history of angle closure or PAS. Can also occur in eyes with open angle or following
   cataract surgery or various laser procedures. Malignant glaucoma presents with uniform
   flattening of both the central and peripheral anterior chamber. Miotics can make malignant
   glaucoma worse and should not be used.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

– Gonioscopy
– US biomicroscopy
– AS-OCT

Test Interpretation

Narrow or closed anterior chamber angle

TREATMENT

ALERT

For patients with acute symptoms (severe eye pain, blurred vision, eye redness, halos around
lights/objects, headache, nausea and vomiting) and asymmetric pupillary response, obtain
immediate consultation with ophthalmology.

GENERAL MEASURES

– Goals of treatment:
  – Reverse or prevent angle-closure process
  – Control IOP
  – Prevent damage to the optic nerve
– PACS
  – Majority will not develop PAC or PACG.
  – May be either observed for development of PAC or be treated with laser peripheral
    iridotomy (LPI)
– PAC and PACG
  – Iridotomy performed using argon or Nd:YAG laser
  – Complications of iridotomy: cataract; increased IOP; laser burn to the cornea, lens, or
    retina; late-onset corneal edema; development of posterior synechiae; hyphema; iritis; and
    ocular dysphotopsia
– AACC
  – Initial treatment of AACC is to lower the IOP with medications to relieve the acute
    symptoms followed by iridotomy as soon as possible.

MEDICATION

– During acute attack, medical therapy lowers IOP to relieve symptoms and clear corneal edema
so that iridotomy can be performed as soon as possible.

- Medical therapy aims at:
  - Reduction of aqueous production:
    - Carbonic anhydrase inhibitors (CAIs): acetazolamide 250–500 mg IV or 250 mg tab × 2 PO at once. Topical CAI such as dorzolamide 2%. CAIs are contraindicated in sulfa allergy and hepatic insufficiency.
    - Topical β-blockers such as timolol 0.5%
    - Topical α₂-agonists such as brimonidine 0.2%
  - Prostaglandin analogues such as latanoprost 0.005% enhance uveoscleral outflow and increase aqueous outflow.
  - Pupillary constriction to open the chamber angle: topical pilocarpine 1% or 2% q 15 min × 3. Miotic therapy may be ineffective when IOP is markedly elevated due to iris sphincter ischemia.
  - Topical steroid such as prednisolone acetate 1% q 15–30 minutes × 4 and then hourly to treat the inflammation.
  - Hyperosmotic agents that reduce the vitreous volume, which in turn reduces IOP:
    - Glycerin 50% solution administered orally, dosage is 1 to 1.5 g/kg. Use with caution if patient has nausea or emesis. To improve the taste, the solution may be mixed with a small amount of orange juice and poured over crushed ice.
    - Mannitol 20% solution, administered IV at 2 g/kg of body weight over 30 minutes.
  - Hyperosmotic agent should be used with caution in patients with heart and kidney disease. Glycerin can increase blood sugar level and should not be given to diabetic patients.
- During acute attack, acetazolamide 500 mg IV is given followed by 500 mg PO BID. Topical therapy is initiated with 0.5% timolol maleate and 1% apraclonidine drops 1 minute apart. Reduction of inflammation is accomplished with frequent topical steroids. In addition, systemic therapy with mannitol 20% 1.5 to 2.0 g/kg infused over 30 to 60 minutes or oral glycerol (Osmoglyn) (50%) 6 oz PO may be needed. Treat pain and nausea with analgesics and antiemetics. Initiate treatment with 3 doses of pilocarpine drops administered 15 minutes apart to cause miosis in an attempt to open the angle.

SURGERY/OTHER PROCEDURES

- Definitive therapy for PAC, PACG, and AACC is Nd:YAG or argon laser iridotomy. Iridotomy can be performed temporally or superiorly.
- Surgical iridectomy may be performed if cornea is cloudy and laser iridotomy cannot be performed.
- Plateau iris syndrome may be initially treated by either LPI or lensectomy if cataract is present. Eyes with plateau iris syndrome remain predisposed to angle closure despite a patent iridotomy or lensectomy.
  - Argon laser peripheral iridoplasty may be needed to flatten and thin the peripheral iris.
- Growing evidence shows cataract extraction alone can lower IOP and reduce the risk of lens-induced angle closure; this can be considered as a treatment option in appropriate cases. Other procedures to reduce IOP include argon laser peripheral iridoplasty (especially for plateau iris syndrome), anterior chamber paracentesis, goniosynechialysis, and trabeculectomy.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Half of the patients with AACC will develop AACC in the other eye within 5 years. Hence, prophylactic LPI should be performed in the other eye as soon as possible.

PATIENT EDUCATION
- Advise patient to seek emergency medical attention if experiencing a change in visual acuity, blurred vision, eye pain, or headache.
- Patients with PACS and no iridotomy; avoid use of decongestants, motion sickness medications, adrenergic agents, antipsychotics, antidepressants, and anticholinergic agents.

PROGNOSIS
- With timely treatment, most patients do not have permanent vision loss.
- Prognosis depends on ethnicity, underlying eye disease, and time to treatment.
- After LPI, most PACS subjects can be expected to have no further treatment (2)[A].
  - In contrast, many PAC and APAC eyes, and most PACG eyes, are given additional treatment to control IOP after LPI.
- Chronic angle closure may develop after acute angle closure in which synechial closure persists. It can also develop when the angle gradually closes and the angle function becomes progressively compromised leading to a slow rise in IOP. Vision loss may be the presenting complaint because of the asymptomatic nature of the condition.

COMPLICATIONS
- Chronic angle closure
- Iris atrophy
- Cataract
- Optic atrophy
- Malignant glaucoma
- Central retinal artery/vein occlusion
- Permanent decrease in visual acuity
- Repeat episode
- Fellow (contralateral) eye attack
- Blindness

REFERENCES
CODES

ICD10

- H40.20X0 Unsp primary angle-closure glaucoma, stage unspecified
- H40.219 Acute angle-closure glaucoma, unspecified eye
- H40.2290 Chronic angle-closure glaucoma, unsp eye, stage unspecified

CLINICAL PEARLS

For patients with acute symptoms (severe eye pain, blurred vision, eye redness, halos around lights/objects, headache, nausea and vomiting) and asymmetric pupillary response, obtain immediate consultation with ophthalmologist.
Primary open-angle glaucoma (POAG) is an optic neuropathy resulting in visual field loss frequently associated with increased intraocular pressure (IOP). Normal IOP is 10 to 22 mm Hg.

Glaucomatous optic nerve damage also can occur with normal IOP and as a secondary manifestation of other disorders such as corticosteroid-induced glaucoma.

Pregnancy Considerations
Prostaglandins should be avoided during pregnancy in the treatment of POAG.

Incidence
- Predominant age: usually >40 years
- Predominant gender: male = female

Prevalence
Prevalence in persons >40 years of age is ~1.8%.

Etiology and Pathophysiology
Normally, aqueous is produced by the ciliary epithelium of the ciliary body and is secreted into the posterior chamber of the eye. Aqueous then flows through the pupil and enters the anterior chamber to be drained by the trabecular meshwork (TM) in the iridocorneal angle of the eye. It then drains into the Schlemm canal and then into the episcleral venous system. 5–10% of the total aqueous outflow leaves via the uveoscleral pathway.

- Impaired aqueous outflow through the TM; increased resistance within the aqueous drainage system

Genetics
- A family history of glaucoma increases the risk for developing glaucoma.
- TMCO1 genotype has been found to increase the risk of developing glaucoma among non-Hispanic whites
- The myocilin (MYOC) gene was the first gene associated with POAG.

Risk Factors
- Increased IOP
- Myopia
- Diabetes mellitus (DM)
- African American
- Elderly
- Hypothyroidism
- Positive family history
- Central corneal thickness <550 μm
- Larger vertical cup-to-disc ratio (CDR)
- Larger horizontal CDR
- CDR asymmetry
- Disc hemorrhage
- Prolonged use of topical, periocular, inhaled, or systemic corticosteroids
- Systemic calcium-channel blockers
- Prior history pars plana vitrectomy
- Obstructive sleep apnea
- Hypertension
- Elevated serum cholesterol levels
- Corneal hysteresis (CH): A measure of the viscoelastic damping of the cornea. Lower CH associated with faster rates of visual field loss.

GENERAL PREVENTION
- Possible reduced risk of POAG with long-term use of oral statins among persons with hyperlipidemia
- Higher dietary nitrate and green leafy vegetable intake has been associated with a lower POAG risk. Evidence suggests that nitrate, a precursor of nitric oxide, is beneficial for blood circulation.
  - The vascular endothelium regulates the microcirculation via vasoactive factors with nitric oxide being one of them. Nitric oxide reduces IOP by causing relaxation of the TM and Schlemm canal, resulting in increased aqueous humor outflow.

DIAGNOSIS

HISTORY
Painless, slowly progressive visual loss; patients are generally unaware of the visual loss until late in the disease. Central visual acuity remains unaffected until late in the disease.

PHYSICAL EXAM
- Visual acuity and visual field assessment
- Ophthalmoscopy to assess optic nerve for glaucomatous damage
- Tonometry to measure IOP. The IOP may be elevated or within the normal range.
- CDR >0.5: Normal eyes show a characteristic configuration for disc rim thickness of inferior ≥ superior ≥ nasal ≥ temporal (ISNT rule).
  - Earliest visual field defects are paracentral scotomas and peripheral nasal steps.

DIFFERENTIAL DIAGNOSIS
- Normal-tension glaucoma
- Optic nerve pits
- Anterior ischemic optic neuropathy
- Compressive lesions of the optic nerve or chiasm
- Posthemorrhagic (shock optic neuropathy)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Optical coherence tomography (OCT) can be useful in the detection of glaucoma.
The retinal nerve fiber layer (RNFL) is primarily composed of the axons of the retinal ganglion cells (RGCs).

- Glaucoma involves not only the RGC axons but also the bodies and dendrites.
- RGC axonal thickness is greatest at the peripapillary retina; therefore, OCT measures the peripapillary RNFL.
- RGCs are concentrated in the macula; therefore, OCT measurements of the macular ganglion cell–inner plexiform layer (mGCIPL) can determine glaucoma progression by the thinning of the mGCIPL.
- RNFL is thinner in patients with glaucoma.
- RNFL tends to be thinner with older age, in Caucasians, greater axial length, and smaller optic disc area.
- Significant RGC loss may occur at specific location before corresponding visual field loss is detected.

### Diagnostic Procedures/Other

- Visual field testing: perimetry
- Tonometry to measure IOP

### Test Interpretation

- Atrophy and cupping of optic nerve
- Loss of RGCs and their axons produces defects and thinning in the RNFL. Assessment of RNFL thickness with OCT can detect glaucomatous damage before the appearance of visual field defects on standard automated perimetry.

RNFL OCT utility declines in advanced glaucoma, whereas the mGCIPL OCT remains a sensitive progression detector from early to advanced glaucoma (1)[A].

---

**TREATMENT**

### GENERAL MEASURES

- **Early Manifest Glaucoma Trial**
  - Clinical trial comparing observation to treatment with betaxolol combined with argon laser trabeculoplasty
    - Early treatment delays progression.
    - The magnitude of initial IOP reduction influences disease progression.
- **Ocular Hypertension Treatment Study**
  - Patients who only had increased IOP in the range of 24 to 32 mm Hg were treated with topical ocular hypotensive medication.
  - Treatment produced ~20% reduction in IOP.
  - At 5 years, treatment reduced the incidence of POAG by >50%: 9.5% in the observation group versus 4.4% in the medication-treated group.
- **Advanced Glaucoma Intervention Study**
  - Eyes were randomized to laser trabeculoplasty or filtering surgery when medical therapy failed.
  - In follow-up, if IOP was always <18 mm Hg, visual fields tended to stabilize. When IOP was >17 mm Hg, >1/2 the time, patients tended to have worsening of visual fields.
- **Collaborative Initial Glaucoma Treatment Study**
Both initial medical and surgical (trabeculectomy) treatment achieved significant IOP reduction, and both had little visual field loss over time.

**MEDICATION**

More than one medication, with different mechanisms of action, may be needed. Ocular hypotensive agent categories include the following:

- **Prostaglandin analogues:** generally used as first-line treatment. Enhance uveoscleral outflow and increase aqueous outflow through the TM: latanoprost 0.005% one drop at bedtime; travoprost 0.004% one drop at bedtime; bimatoprost 0.01% one drop at bedtime.
- **Latanoprostene bunod,** 0.024% solution, This is a combination drug with one of the actions being the release of nitric oxide. Instill one drop at bedtime.
  - **Contraindications/precautions**
    - Prostaglandin analogues may cause increased pigmentation of the iris and periorbital tissue.
    - Increased pigmentation and growth of eyelashes
    - Should be used with caution in active intraocular inflammation (iritis/uveitis)
    - Caution is also advised in eyes with risk factors for herpes simplex, iritis, and cystoid macular edema.
    - Macular edema may be a complication associated with treatment.
    - Avoid during pregnancy.

- **β-Adrenergic antagonists (nonselective and selective):** decrease aqueous formation; best when used as an add-on therapy: timolol 0.25% (initial) to 0.5% one drop in affected eye q12h; gel-forming solution (0.25% or 0.5%) one drop in affected eye once daily; betaxolol 0.5% one drop affected eye BID
  - **Nonselective β-adrenergic antagonists:** Avoid in asthma, chronic obstructive pulmonary disease (COPD), 2nd- and 3rd-degree atroventricular (AV) block, and decompensated heart failure. Betaxolol is a selective β-adrenergic antagonist and is safer in pulmonary disease.
  - β-Adrenergic antagonists: caution in patients taking calcium antagonists because of possible AV conduction disturbances, left ventricular failure, or hypotension

- **Adrenergic agonists (selective α2-adrenergic agonists)**
  - **Brimonidine tartrate 0.1%:** One drop TID (α2-adrenergic agonist) decreases aqueous formation and increases uveoscleral outflow.

- **Carbonic anhydrase inhibitors (oral, topical):** decrease aqueous formation
  - **Acetazolamide:** 250 mg PO 1 to 4 times per day
  - **Dorzolamide 2%:** one drop TID
  - **Brinzolamide 1%:** one drop TID
  - **Carbonic anhydrase inhibitors**
    - Do not use with sulfa drug allergies.
    - Do not use with cirrhosis because of the risk of hepatic encephalopathy.

- Rho kinase (Rock) inhibitors lower IOP by increasing aqueous outflow through the trabecular outflow pathway by decreasing actomyosin-driven cellular contraction and reducing production of fibrotic extracellular matrix proteins.
– Netarsudil 0.02%: one drop once daily in the evening
– Corneal verticillata, or whorl keratopathy can occur with its usage.

- Parasympathomimetics (miotics), including direct-acting cholinergic agonists increase aqueous outflow
  – Pilocarpine 1–4%: one drop in affected eye BID–QID (direct-acting cholinergic agonist)
  – Parasympathomimetics (miotic): cause pupillary constriction and may cause decreased vision in patients with a cataract; may cause eye pain or myopia due to increased accommodation. All miotics break down the blood–aqueous barrier and may induce chronic iridocyclitis.

- Hyperosmotic agents: increase blood osmolality, drawing water from the vitreous cavity
  – Mannitol 20% solution is administered IV at 2 g/kg of body weight over a period of 30 minutes.
  – Glycerin 50% solution is administered orally; dosage is 1 to 1.5 g/kg, this is usually 4 to 7 oz. To improve the taste the solution may be mixed with a small amount of orange juice and poured over crushed ice.
  – Hyperosmotic agents: caution in diabetics; dehydrated patients; and those with cardiac, renal, and hepatic disease.

- Contact lens wearers: Many glaucoma drops contain benzalkonium chloride; remove contact lens prior to administration and wait 15 minutes before reinsertion.

**SURGERY/OTHER PROCEDURES**

- Argon laser trabeculoplasty (ALT)
  – Can be applied up to 180 degrees of the TM
  – Improves aqueous outflow
  – The Glaucoma Laser Trial Research Group showed in newly diagnosed, previously untreated patients with POAG that ALT was as effective as topical glaucoma medication within the first 2 years of follow-up.

- Selective laser trabeculoplasty (SLT)
  – 532-nm Nd:YAG laser
  – Appears to be as effective as ALT in lowering IOP
  – May be repeated if necessary

- Trabeculectomy (glaucoma filtering surgery)
  – Usually reserved for patients needing better IOP control after maximal medical therapy and who may have previously undergone an ALT/SLT
  – Mitomycin C can be applied at the time of surgery to increase the chances of a surgical success.

- Shunt (tube) surgery
  – For example, Molteno and Ahmed devices
  – Generally reserved for difficult glaucoma cases in which conventional filtering surgery has failed or is likely to fail

- Tube Versus Trabeculectomy (TVT) study
  – After 5 years of follow-up, both procedures were associated with similar IOP reduction and the number of glaucoma medications needed.

- Ciliary body ablation: indicated to lower IOP in patients with poor visual potential or those who are poor candidates for filtering or shunt procedures

- Minimally invasive glaucoma surgery (MIGS) is frequently combined with cataract surgery; currently targeted at patients with mild to moderate glaucoma
– Schlemm canal stents
  o iStent, Hydrus
– Suprachoroidal stents
  o iStent Supra, CyPass (CyPass has been voluntarily withdrawn because of concerns regarding corneal endothelial cell loss)
– Subconjunctival stents
  o Xen, InnFocus
  – The Kahook Dual Blade performs an excisional goniotomy removing a strip of TM.

* Cataract extraction can decrease IOP in patients with ocular hypertension.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Monitor vision and IOP every 3 to 6 months.
- Visual field testing every 6 to 18 months
- Optic nerve evaluation every 3 to 18 months, depending on POAG control
- A worsening of the mean deviation by 2 dB on the Humphrey field analyzer and confirmed by a single test after 6 months had a 72% probability of progression.
- The IOP response to ocular hypotensive agents tends to be reduced in persons with thicker corneas.

**PATIENT EDUCATION**

POAG is a silent robber of vision, and patients may not appreciate the significance of their disease until much of their visual field is lost.

**PROGNOSIS**
- With standard glaucoma therapy, the rate of visual field loss in POAG is slow.
- Patients still may lose vision and develop blindness, even when treated appropriately.
- The structure of the mGCIPL was better preserved in surgically treated eyes than in medically treated eyes, even when the IOPs were similar during follow-up in cases of advanced glaucoma.[B]

**COMPLICATIONS**

Blindness

**REFERENCES**

ICD10
- H40.11X0 Primary open-angle glaucoma, stage unspecified
- H40.11X1 Primary open-angle glaucoma, mild stage
- H40.11X2 Primary open-angle glaucoma, moderate stage

CLINICAL PEARLS
- Painless, slowly progressive visual loss; patients generally are unaware of the visual loss until late in the disease. Central visual acuity remains unaffected until late in the disease.
- Patients still may lose vision and develop blindness, even when treated appropriately.
- Topical or system steroids can cause the IOP to increase.
ACUTE GLOMERULONEPHRITIS
Jonathan T. Lin, MD • Dayyan M. Adoor, MD

BASICS
DESCRIPTION

• Acute glomerulonephritis (GN) is an inflammatory process involving the glomerulus of the kidney, resulting in a clinical syndrome consisting of hematuria, proteinuria, and renal insufficiency, often in association with hypertension and edema.

• Acute GN may be caused by primary glomerular disease or secondary to systemic disease.
  – Infection-related GN (also postinfectious GN)
  – IgA nephropathy/Henoch-Schönlein purpura (HSP)
  – Antiglomerular basement membrane disease (anti-GBM disease)
  – Antineutrophil cytoplasmic antibody (ANCA)-associated GN
  – Membranoproliferative GN (MPGN)
  – Lupus nephritis
  – Cryoglobulin-associated GN

• Clinical severity ranges from self-limited asymptomatic microscopic or gross hematuria to a rapidly progressive loss of kidney function over days to weeks, termed rapidly progressive GN (RPGN).
  – In patients with RPGN, kidney biopsy often demonstrates crescentic GN, which usually warrants urgent and aggressive treatment.

ALERT
Urgent investigation and treatment are required to avoid irreversible loss of kidney function.

EPIDEMIOLOGY

• Infection-related GN
  – Postinfectious GN most commonly manifests after resolution of group certain nephritogenic strains of group A β-hemolytic Streptococcus infection
  – Can also occur as a result of other bacterial infections, such as infective endocarditis or shunt nephritis, or less commonly with viral, helminthic, or parasitic infections
  – Accounts for 80% of acute GN in children

• IgA nephropathy
  – Most common primary GN in the world
  – Most common in the 2nd and 3rd decades but can occur at any age
  – Incidence differs geographically: Asia > United States
  – Populations of East Asian ancestry are at increased risk for IgA nephropathy, and some genetic factors have been identified.
  – HSP, the form with extrarenal manifestations, can occur at any age but typically occurs in children <10 years old.

• Anti-GBM disease
  – Can cause Goodpasture disease, a notable cause of the pulmonary–renal syndrome
  – Peak distribution in 3rd and 6th decades

• ANCA-associated GN
– Often has a relapsing and remitting course
– Four disease presentations:
  o Granulomatosis with polyangiitis (GPA), formerly Wegener granulomatosis
  o Microscopic polyangiitis (MPA)
  o Isolated pauci-immune GN—when isolated to kidneys
  o Eosinophilic GPA, formerly Churg-Strauss disease—GN relatively common but renal involvement rarely severe
– Older patients are more commonly affected, although this GN can affect any age group.

● MPGN
  – May be primary (idiopathic) or secondary to systemic diseases
  – Epidemiology varies depending on the mechanism of injury.

● Lupus nephritis
  – 30–70% of systemic lupus patients will have renal involvement.
  – Incidence of lupus nephritis is higher among black populations in comparison to white populations.

● Cryoglobulin-associated vasculitis
  – 80% of cases with hepatitis C virus (HCV) infection
  – May also be associated with autoimmune disease or dysproteinemia

ETIOLOGY AND PATHOPHYSIOLOGY
● In general, systemic and/or local immune activation causes glomerular injury.
● Immune-complex mediated: from antigen–antibody formation and deposition in the kidneys
  – Postinfectious GN: host immune reaction to nephritogenic streptococci strains as a trigger
  – IgA nephropathy: abnormal glycosylation of IgA, leads to its mesangial deposition; etiology poorly understood
  – MPGN: typically secondary to systemic diseases, such as chronic infections (hepatitis C, hepatitis B), autoimmune diseases, monoclonal gammopathies, and complement dysregulation
  – Lupus nephritis: autoimmune disease
  – Cryoglobulin-associated GN: inflammation from complexes known as cryoglobulins, named for their property of precipitating as lower temperatures
● Direct antibody-mediated injury:
  – Anti-GBM disease: caused by autoantibodies that target type IV collagen of basement membranes
● Pauci-immune GN
  – ANCA-associated GN: autoantibodies against neutrophil granules involved in pathogenesis
● Alternative complement pathway dysregulation:
  – C3 glomerulopathy: subtype of MPGN with predominant C3 without immunoglobulin staining on immunofluorescence; includes dense deposit disease (DDD) and C3GN

Genetics
Genetic factors are likely to play a role in susceptibility to many of the acute GNs, although these have not been sufficiently defined to be clinically useful in most circumstances.

RISK FACTORS
● Epidemics of nephritogenic strains of streptococci are triggers for postinfectious GN.
● Anti-GBM disease has been associated with prior pulmonary injury and inhalation exposures,
such as hydrocarbon solvents
- ANCA-associated GN may be drug induced (e.g., hydralazine, levamisole-contaminated cocaine) and is also associated with environmental exposures such as silica.
- Infection with hepatitis B or C is associated with MPGN.
- Infection with hepatitis C is a risk factor for developing cryoglobulinemic GN.
- Mutations in alternate complement pathway genes are associated with increased risk of developing complement-mediated MPGN.

**GENERAL PREVENTION**
Early detection is paramount.

---

**DIAGNOSIS**

**HISTORY**
- Patients may report cola- or tea-colored urine and decreased urine volume.
- Edema occurs in many patients, typically in face and lower extremities.
- Shortness of breath may occur with significant fluid overload.
- Generalized malaise
- Timing
  - Poststreptococcal GN typically occurs 1 to 3 weeks after pharyngitis or 2 to 6 weeks after skin infection.
  - IgA nephropathy may present within several days after an acute infection.
  - Patients may also present with complaints more specific to the associated disease:
    - Joint pain or rash in lupus nephritis
    - Hemoptysis in pulmonary–renal syndromes (see “Physical Exam”)
    - Sinusitis, pulmonary infiltrates, arthralgias in ANCA-associated GN
    - Abdominal or joint pain and purpura in IgA–HSP
    - Purpura and skin vasculitis in cryoglobulinemia-associated GN

**PHYSICAL EXAM**
- A complete physical exam may discover clues to systemic disease as a potential cause.
- Majority of patients will have normal exam, but can often present with hypertension and signs of fluid overload.
- Sinus disease: often with ANCA-associated GN/GPA
- Pharyngitis or impetigo: postinfectious GN or IgA nephropathy
- Pulmonary hemorrhage (pulmonary–renal syndrome): anti-GBM disease/Goodpasture, ANCA-associated GN, or lupus nephritis
- Hepatomegaly or liver tenderness could point to cryoglobulinemia-associated GN or IgA nephropathy.
- Purpura may point to ANCA-associated GN or HSP/IgA nephropathy.

**DIFFERENTIAL DIAGNOSIS**
- Nonglomerular hematuria: trauma, prostate diseases, urologic cancer, cystitis, nephrolithiasis, renal cysts, thrombotic microangiopathy

**DIAGNOSTIC TESTS & INTERPRETATION**
Initial Tests (lab, imaging)
Urinalysis with examination of sediment
- Dysmorphic red blood cells (RBCs) or RBC casts on urine microscopy indicate glomerular hematuria and strongly suggest the diagnosis of an acute GN.
- Pyuria and white blood cell casts may also be present.

Proteinuria: 24-hour collection or random urine protein/creatinine ratio
- Can be mild to severe proteinuria, occasionally nephrotic range

Electrolytes, blood urea nitrogen, creatinine, complete blood count

Serologies, depending on clinical presentation, may help clarify etiology:
- Antistreptolysin O titer, streptozyme: often positive in poststreptococcal GN
- Complement levels (C3, C4):
  - C3 low in infection-related GN
  - Both C3 and C4 can be low in lupus nephritis and MPGN.
  - C4 typically low in cryoglobulinemia
- Antinuclear antibody (ANA) to rule out lupus nephritis
- ANCA screen: myeloperoxidase and anti-proteinase 3 antibodies
- Anti-GBM antibody
- Hepatitis B surface antigen and antibody
- Hepatitis C antibody
- Cryoglobulins (must be sent warm)
- Rheumatoid factor
- HIV testing
- Serum free light chain to assess for monoclonal gammopathies

A chest x-ray may be useful in the setting of hemoptysis or a suspected infiltrate on exam.

**Test Interpretation**

Renal biopsy
- If clinical picture is consistent with postinfectious GN in a child, a biopsy may not be required.
- If there is clinical suspicion for other causes of acute GN, renal biopsy should be done.

Light microscopy
- Diffuse hypercellularity suggests a proliferative disease such as IgA nephropathy, lupus nephritis, or postinfectious GN.
- Presence of glomerular crescents correlates with RPGN and disease severity.

Immunofluorescence
- Pattern of IgG, IgA, IgM, C3, and C4 staining may aid in characterizing the GN.
- Isolated mesangial IgA staining is pathognomonic for IgA nephropathy.
- Crescentic GN in absence of immune complex staining suggests ANCA-associated GN.
- Lupus nephritis typically positive for all immunoglobulins and complements (“full house”)

Electron microscopy: The location of immunoglobulin deposits is useful in pointing to a particular diagnosis.

**TREATMENT**

**MEDICATION**

**First Line**
- Hypertension
  - Diuretics are useful for management of salt retention and edema.
Calcium channel blockers
- Avoid angiotensin-converting enzyme (ACE) inhibitors or angiotensin receptor blockers (ARBs) if acute renal dysfunction is present.
- Peripheral edema: Loop diuretics are often required due to the degree of edema.
- Pulmonary edema: oxygen and diuretics

**Second Line**
- Each of the glomerular diseases often requires a specific treatment plan based on renal biopsy results; therefore, a nephrologist is often guiding care.
- Supportive care is typically adequate in postinfectious GN.
- Crescents on renal biopsy may be an indication for steroids in postinfectious GN and, in other cases, are often an indication for additional potent immunosuppressive medications (1)[C].
- Treatment with antiviral therapy for nephritic syndromes that have been shown to be secondary to underlying viral infections such as HCV and hepatitis B virus (HBV). Additional immunosuppressive medication may be warranted for severe renal disease.
- Commonly used immunosuppressive medications include
  - Corticosteroids—may consider initiation in high doses even prior to kidney biopsy (1)[C]
  - Cyclophosphamide
  - Mycophenolate mofetil (MMF)
  - Calcineurin inhibitors (cyclosporine, tacrolimus)
  - Rituximab
- Choice of immunosuppressive agent depends on patient characteristics and the disease process.
  - In addition to steroids, typical induction immunosuppression regimens include either cyclophosphamide or rituximab for ANCA-associated renal disease and cyclophosphamide or MMF for proliferative forms of lupus nephritis. In patients at risk of relapse after achieving remission, maintenance immunosuppression should be considered (1)[C],(2,3)[A].
  - IgA nephropathy: ACE inhibitors or ARBs recommended for patients with proteinuria (1,4)[C]. Additional steroids and immunosuppression may be considered in refractory cases (1)[C].
  - MPGN: Treat underlying cause in secondary type.
  - Anti-GBM: Treatment consists of a combination of immunosuppressants and plasmapheresis (4)[C].
- Plasmapheresis may also be considered in some cases for RPGN or ANCA-associated renal disease with diffuse pulmonary hemorrhage (1)[C],(2,5)[A].
- Dialysis may be needed for uremia, hyperkalemia refractory to medical management, intractable acidosis, and diuretic-resistant pulmonary edema.

**ISSUES FOR REFERRAL**
- Consultation with a nephrologist is usually required to assist with renal biopsy to confirm diagnosis and assist with management.
- Consultation with a rheumatologist may also be helpful in cases with systemic manifestations.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Consider admission for patients with no urine output, rapidly deteriorating renal function, significant hypertension, and suspicion of pulmonary hemorrhage or fluid overload that is compromising heart or respiratory function.
• Hemodynamically stable patients without complications may be managed as outpatients.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Depends on type of GN
- Regular blood pressure checks and urinalysis to detect recurrence, assessment of renal function to detect acute or follow chronic renal disease as a result of the primary event, and regular clinical assessment to detect suspicious symptoms that may herald a recurrence (i.e., rash, joint complaint, hemoptysis)
- Periodic reassessment of serology tests to follow asymptomatic individuals

**DIET**
- No-added-salt diet and fluid restriction until edema and hypertension clear
- Avoid high-potassium foods if significant renal dysfunction is present.
- Moderate dietary protein restriction to 0.8 g/kg per day can be considered.

**PATIENT EDUCATION**
National Kidney Foundation: [https://www.kidney.org/atoz/content/glomerul](https://www.kidney.org/atoz/content/glomerul)

**PROGNOSIS**
- In general, the prognosis depends on the cause of the GN.
- The GN may be self-limited (as often is the case in postinfectious GN) or part of a chronic disease that makes the possibility of recurrence of acute disease likely, with the potential for progressive loss of renal function over time.
- Some forms of acute GN (including ANCA-associated and severe lupus) require long-term immunosuppression to prevent recurrence.

**COMPLICATIONS**
- Hypertensive retinopathy and encephalopathy
- Microscopic hematuria may persist for years.
- Chronic kidney disease
- Nephrotic syndrome (~10%)

CODES

ICD10
- N00.9 Acute nephritic syndrome with unsp morphologic changes
- N00.2 Acute nephritic syndrome w diffuse membranous glomrlneph
- N00.8 Acute nephritic syndrome with other morphologic changes

CLINICAL PEARLS
- Dysmorphic RBCs and RBC casts are a key component of the urinalysis in GN.
- Postinfectious GN in children is typically a self-limited disease.
- Searching for other organ involvement is useful in establishing a definitive diagnosis.
- With the discovery of a GN, monitor the initial renal function labs frequently to identify an RPGN.
- Clinical course and treatment strategies depend on the underlying disease process.
GLOMERULONEPHRITIS, POSTINFECTIONOUS
Theodore B. Flaum, DO, FACOFP • Samantha Faryn Gottlieb, DO, MS

BASICS
DESCRIPTION
Postinfectious glomerulonephritis (PIGN) is an immune complex disease associated with nonrenal infection by certain strains of bacteria, most commonly Streptococcus and Staphylococcus. The most common form of PIGN, poststreptococcal glomerulonephritis (PSGN), is preceded by Streptococcus and predominantly affects children. The clinical presentation varies from asymptomatic to the acute nephritic syndrome, characterized by gross hematuria, proteinuria, edema, hypertension (HTN), and acute kidney injury.

EPIDEMIOLOGY
A global decline in incidence, especially in developed countries is attributed to better hygiene and a decreased incidence of streptococcal skin infections. Despite this, PIGN is the most common cause of acute nephritis in children globally, of which 97% of cases occur in developing countries. PSGN is primarily a pediatric disease, but a recent increase has been seen in nonstreptococcal GN in adults.

Incidence
• New cases of PSGN in developing countries range from 8.5 to 28.5 per 100,000 persons per year
• Pediatrics: 24.3 cases/100,000 persons per year in developing countries; 6 cases/100,000 persons per year in developed countries
• Adults: 2 cases/100,000 persons per year in developing countries; 0.3 cases/100,000 persons per year in developed countries
• Worldwide: 34% of cases are now seen in adults with a global burden of 68,000 cases per year.
• Estimated incidence of 470,000 and 5,000 deaths per year globally.
• Male > female (2:1)

ETIOLOGY AND PATHOPHYSIOLOGY
• Glomerular immune complex disease induced by specific nephritogenic strains of bacteria:
  – >95% of cases are caused by Group A β-hemolytic Streptococcus (GAS) (1)
  – Staphylococcus (predominantly Staphylococcus aureus; more commonly methicillin-resistant S. aureus [MRSA], occasionally coagulase-negative Staphylococcus)
  – Gram-negative bacteria including Escherichia coli, Yersinia, Pseudomonas, and Haemophilus (2)
  – or occasionally viral, fungal, helminthic, or protozoal causes.
• Proposed mechanisms for the glomerular injury (3):
  – Deposition of circulating immune complexes with streptococcal or staphylococcal antigens—these complexes can be detected in patients with streptococcal- or staphylococcal-related GN but do not correlate to disease activity.
  – Note: IgG is the most frequent immunoglobulin in PSGN (2).
In situ immune complex formation from deposition of antigens within the glomerular basement membrane (GBM) and subsequent antibody binding.

In situ glomerular immune complex formation promoted by antibodies to streptococcal or staphylococcal antigens.

Alteration of normal renal antigen leading to molecular mimicry that elicits an autoimmune response.

Glomerular immune complex causing complement activation and inflammation:
- Nephritis-associated plasmin receptor (NAP1r): activates plasmin, contributes to activation of the alternative complement pathway.
- Streptococcal pyrogenic exotoxin B (SPE B): binds plasmin and acts as a protease; promotes the release of inflammatory mediators.

Activation of the alternative complement pathway causes initial glomerular injury as evidenced by C3 deposition and decreased levels of serum C3. The lectin pathway of complement activation has also been recently implicated in glomerular injury (1,4).

**RISK FACTORS**
- Children 5 to 12 years of age.
- Older patients (>65 years of age):
  - Patients with immunocompromising comorbid conditions.
  - Diabetes.
  - Alcohol abuse.

**GENERAL PREVENTION**
- Early antibiotic treatment for streptococcal and staphylococcal infections, when indicated, although efficacy in preventing GN is uncertain.
- Improved hygiene.
- Prophylactic penicillin treatment to be used in closed communities and household contacts of index cases in areas where PIGN is prevalent.

**COMMONLY ASSOCIATED CONDITIONS**
Commonly streptococcal or staphylococcal infection.

**DIAGNOSIS**

**HISTORY**
- Patients present with acute nephritic syndrome, characterized by sudden onset of hematuria associated with edema and HTN 1 to 2 weeks after an infection.
- A triad of edema, hematuria, and HTN is classic, but not always seen.
- Urine described as “tea-colored” or “cola-colored.”
- PIGN in children usually follows GAS skin/throat infection.
- The latent period between GAS infection and PIGN depends on the site of infection: 1 to 3 weeks following GAS pharyngitis and 3 to 6 weeks following GAS skin infection.
- Adult PIGN most commonly follows staphylococcal infections (3 times more common than streptococcal infections) of the upper respiratory tract, skin, heart, lung, bone, or urinary tract. Studies show 7–16% of cases of adult PIGN have no preceding evidence of infection and, in 24–59%, the offending microorganism cannot be identified (5)[A].
PHYSICAL EXAM

- **Constitutional:**
  - Fever: 40–50% of patients

- **Cardiovascular:**
  - Edema: present in ~2 of 3 adult patients due to sodium and water retention; less common in pediatric patients
  - HTN: present in 80–90% of patients and varies from mild to severe; secondary to fluid retention. Hypertensive encephalopathy is an uncommon but serious complication.

- **Pulmonary:**
  - Respiratory distress: due to pulmonary edema (rare)

- **Genitourinary:**
  - Gross hematuria: present in 25–60% of patients
  - Microscopic hematuria: subclinical cases of PIGN
  - Oliguria: present in 18–51% of patients
  - Azotemia/impaired renal function: 44–70% or patients
  - Proteinuria: ~90% of patients

- **Neuro:**
  - rarely: encephalopathy, seizure

DIFFERENTIAL DIAGNOSIS

The diagnosis of PIGN is generally by history once the diagnosis of acute nephritis is made, with documentation of a recent infection and nephritis beginning to resolve 1 to 2 weeks after presentation. However, with progressive disease >2 weeks, persistent hematuria/HTN >4 to 6 weeks, or no adequate documentation of a GAS or other infection, the differential diagnosis of GN needs to be considered and renal biopsy ordered:

- **Membranoproliferative glomerulonephritis (MPGN):** The presentation of MPGN may be indistinguishable initially with hematuria, HTN, proteinuria, and hypocomplementemia after an upper respiratory infection. However, patients with MPGN continue to have persistent nephritis and hypocomplementemia beyond 4 to 6 weeks and possibly also have a further elevation in serum creatinine. Patients with PIGN tend to have resolution of their disease and a return of normal C3 and CH50 levels within 2 to 4 weeks.

- **Secondary causes of GN:** Lupus nephritis and Henoch-Schönlein purpura nephritis have features similar to PIGN. Extrarenal manifestations and laboratory tests for these underlying systemic diseases help differentiate them from PIGN. Hypocomplementemia is not characteristic of Henoch-Schönlein purpura, and the hypocomplementemia that occurs in lupus nephritis is with reductions in both C3 and C4, whereas C4 levels are normal in PIGN.

- **IgA nephropathy** often presents after an upper respiratory infection. It can be distinguished from PIGN based on a shorter time frame between the upper respiratory illness and hematuria, as well as history of gross hematuria, as PIGN recurrence is rare. IgA nephropathy is a chronic illness and will recur. Patients with IgA nephropathy have normal C3/C4 levels.

- **IgA-dominant acute PIGN:** a recently recognized form of PIGN occurring in poststaphylococcal GN. This differs from primary IgA nephropathy in that these patients do not have a history of renal disease. The terms IgA-dominant PIGN and poststaphylococcal GN have been debated because such cases are described in association with active staphylococcal infection. Emerging terms include IgA-dominant infection-related GN or staphylococcus-associated GN (2).

- **Pauci-immune crescentic GN:** In elderly patients with severe renal failure and active urine
sediment, this is much more common, so antineutrophil cytoplasmic antibody (ANCA) testing should be done (2)[A].

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
Urinalysis shows hematuria; can be with/without RBC casts and pyuria. Proteinuria is present, but nephrotic range proteinuria is uncommon in children (more likely in adults).

**Follow-Up Tests & Special Considerations**
- Culture: PSGN usually presents weeks after a GAS infection; only ~25% of patients will have either a positive throat or skin culture.
- Complement: 90% of pediatric patients (slightly fewer adult patients) will have depressed C3 and CH50 levels in the first 2 weeks of the disease, whereas C2 and C4 levels remain normal. C3 and CH50 levels return to normal within 4 to 8 weeks after presentation.
- Creatinine: elevated to the point of renal insufficiency in 25–83% of cases, more commonly in adults (83%) (4)[A]
- Serology: Elevated titers of antibodies support evidence of a recent GAS infection. Streptozyme test measuring antistreptolysin O (ASO), antihyaluronidase (AHase), antistreptokinase (ASKase), anti–nicotinamide-adenine dinucleotidase (anti-NAD), and anti-DNAse B antibodies: positive in >95% of patients with PSGN due to pharyngitis and 80% with skin infections. In pharyngeal infection, ASO, anti-DNAse B, anti-NAD, and AHase titers are elevated. In skin infections, only the anti-DNAse and AHase titers are typically elevated.

**Diagnostic Procedures/Other**
Renal biopsy is rarely done in children; recommended in most adults to confirm the diagnosis and rule out other glomerulopathies with similar clinical presentations that require immunosuppressive treatment.

**Test Interpretation**
- Light microscopy: diffuse proliferative glomerulonephritis with prominent endocapillary proliferation and numerous neutrophils within the capillary lumen. Deposits may also be found in the mesangium (“starry sky”). Severity of involvement varies and correlates with clinical findings. Crescent formation is uncommon and is associated with a poor prognosis.
- Immunofluorescence microscopy: deposits of C3 and IgG distributed in a diffuse granular pattern
- Electron microscopy: dome-shaped subepithelial electron-dense deposits that are referred to as “humps.” These deposits are immune complexes, and they correspond to the deposits of IgG and C3 found on immunofluorescence. Rate of clearance of these deposits affects recovery time.
- Renal biopsy: usually not performed in most patients to confirm the diagnosis of PIGN as clinical history is highly suggestive and resolution of PIGN typically begins within 1 week of presentation. A biopsy is done when other glomerular disorders are being considered, such as in the case of persistently low C3 levels beyond 6 weeks for possible diagnosis of MPGN, recurrent episodes of hematuria suggestive of IgA nephropathy, or a progressive increase in serum creatinine not characteristic of PIGN.
TREATMENT

MEDICATION
- No specific therapy exists for PIGN, and no randomized controlled trials indicate that aggressive immunosuppressive therapy has a beneficial effect in patients with rapidly progressive crescentic disease. Despite this, patients with >30% crescents on renal biopsy are often treated with steroids (4)[A].
- Older patients often require hospitalization to prevent and treat complications of heart failure (HF) from volume overload (2).
- Management is supportive, with focus on treating the clinical manifestations of PIGN. These include HTN and pulmonary edema:
  - General measures include salt and water restriction and loop diuretics.
  - Calcium channel blockers/angiotensin-converting enzyme (ACE) inhibitors may be used in cases of severe HTN (4)[A].
- Patients with evidence of persistent bacterial infection should be given a course of antibiotic therapy.

SURGERY/OTHER PROCEDURES
Acute dialysis is required in approximately 50% of elderly patients (1,2).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Admission and inpatient observation may be necessary, specifically for elderly patients who are at greater risk for complications such as new-onset or exacerbation of preexisting HF (2).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Repeat urinalysis to check for clearance of hematuria and/or proteinuria.
- Consider other diagnosis if no improvement within 2 weeks.
- Recurrence is rare.

DIET
Renal diet if requiring instances of dialysis

PROGNOSIS
- Most children with PIGN have an excellent outcome, with >90% of cases achieving full recovery of renal function.
- Elderly patients, especially adults, develop HTN, recurrent proteinuria, and renal insufficiency long after the initial illness. Adults with multiple comorbid factors have the worst prognosis and highest incidence of chronic renal injury following PIGN (2).
- Complete remission in adult PIGN is only 26–56%. This has declined since the 1990s, suggesting prognosis is worsening (5).
- The presence of diabetes, higher creatinine levels, and more severe glomerular disease (e.g., crescents) on biopsy are all risk factors for developing end-stage renal disease (2).
REFERENCES

ADDITIONAL READING

CODES

ICD10
- N05.9 Unsp nephritic syndrome with unspecified morphologic changes
- N00.9 Acute nephritic syndrome with unsp morphologic changes

CLINICAL PEARLS

- PIGN is an immune complex disease occurring after infection with certain strains of bacteria, most commonly group A Streptococcus pyogenes.
- The clinical presentation varies from asymptomatic to the acute nephritic syndrome, characterized by gross hematuria, proteinuria, edema, HTN, and acute kidney injury.
- Treatment is primarily supportive and includes treating HTN and edema, along with antibiotics for any ongoing bacterial infection.
- Persistent nephritis and low C3 levels for >2 weeks should prompt evaluation for other causes of GN, such as MPGN or systemic lupus erythematosus nephritis.
CURRENT TOPIC

GLUCOSE INTOLERANCE
Mariya Milko, DO, MS

BASICS

DESCRIPTION
- Glucose intolerance is an intermediate stage between a normal glucose metabolism and diabetes.
- Individuals with impaired fasting glucose (IFG) and/or impaired glucose intolerance (IGT) have been referred to as having prediabetes:
  - IFG: 100 to 125 mg/dL
  - IGT: 140 to 199 mg/dL 2 hours after ingestion of 75 g oral glucose load
  - Hemoglobin A1c (HbA1c) 5.7–6.4% (1)

EPIDEMIOLOGY
- As of 2010, it is estimated that one of every three U.S. adults ≥20 years of age have prediabetes (2).
- An estimated 86 million people in the United States are living with prediabetes.
- Only 11% of people with prediabetes are aware of their condition (3).
- Prediabetes has a 37% prevalence among adults ≥20 years old and 51% of adults ≥65 years in the United States (4).

Incidence
- Systematic review indicates a 5-year cumulative incidence of developing diabetes of 9–25% for people with an HbA1c of 5.5–6.0% and 25–50% with an HbA1c of 6.0–6.5% (1).
- Highest incidence in American Indians/Alaska Natives, non-Hispanic blacks, and Hispanics (2)

Prevalence
From 2009–2012, prevalence of pre-diabetes in the United States was 37% in adults ≥ 20 years old and 51% in adults ≥ 65 years old. According to ADA, in 2015 84.1 million Americans ≥ 18 years old had pre-diabetes. As of 2010, worldwide prevalence was 8%.

ETIOLOGY AND PATHOPHYSIOLOGY
Progressive loss of insulin secretion on the background of insulin resistance (1)

Genetics
Genetic heterogeneity is the concept that diabetes and glucose intolerance can have many different causes. This was first suggested by existence of rare genetic syndromes that cause diabetes, also ethnic differences in clinical features and findings from animal models. It is now firmly established by family, twin, immunologic, and HLA disease association studies.

RISK FACTORS
- Body mass index (BMI) ≥25: overweight
- Obesity and metabolic syndrome
- History of gestational diabetes mellitus (GDM)
- Sedentary lifestyle
Genetic factors. Variants in 11 genes have been shown to be significantly associated with future development of type 2 diabetes and IFG. Variants in 8 of these genes have been associated with impaired β-cell function.

GENERAL PREVENTION

Lifestyle modification with weight reduction and increased physical activity

A decrease in excess body fat provides the greatest risk reduction.

Pregnancy Considerations

Screening for diabetes in pregnancy is based on risk factor analysis:
- High risk: first prenatal visit
- Average risk: 24 to 28 weeks’ gestation

Women with GDM should be screened for diabetes 6 to 12 weeks postpartum with 75-g OGTT and then every 1 to 3 years via any method (5).

COMMONLY ASSOCIATED CONDITIONS

- Obesity (abdominal and visceral obesity)
- Dyslipidemia with high triglycerides (TG)
- Metabolic syndrome
- PCOS
- GDM
- Low HDL
- HTN
- Congenital diseases (Down, Turner, Klinefelter, and Wolfram syndromes)

DIAGNOSIS

Who to screen
- BMI ≥25 or ≥23 for Asian Americans (1)[B]
- Age ≥45 years (1)[B]
- First-degree relative with diabetes
- High TG >250 mg/dL
- Low HDL <35 mg/dL
- HTN: BP >140/90 mm Hg or on treatment
- History of GDM
- Physical inactivity
- History of cardiovascular disease
- Ethnic group at increased risk (non-Hispanic black, Native American, Hispanics, Asian American, Pacific Islander)
- HbA1c ≥5.7%, IGT, or IFG on previous testing
- PCOS
- Conditions associated with insulin resistance such as severe obesity or acanthosis nigricans

HISTORY

- No clear symptoms
- Polyuria
- Polydipsia
- Weight loss
- Blurred vision
- Polyphagia

**PHYSICAL EXAM**
- General physical exam
- BMI assessment

**DIFFERENTIAL DIAGNOSIS**
- Type A insulin resistance
- Leprechaunism
- Rabson-Mendenhall syndrome
- Lipoatrophic diabetes
- Pancreatitis
- Cystic fibrosis
- Hemochromatosis
- Acromegaly
- Cushing syndrome
- Glucagonoma
- Pheochromocytoma
- Hyperthyroidism
- Somatostatinoma
- Aldosteronoma
- Drug-induced hyperglycemia
  - Thiazide diuretics (high doses)
  - β-Blockers
  - Corticosteroids (including inhaled corticosteroids)
  - Thyroid hormone
  - α-Interferon
  - Pentamidine
  - Protease inhibitors
  - Atypical antipsychotics
  - Selective serotonin reuptake inhibitors

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Fasting glucose, 2-hour OGTT, or HbA1c is equally appropriate (1)[B].
- Repeat screen at 3-year intervals with normal results, sooner depending on risk status (1)[C].

**Follow-Up Tests & Special Considerations**
- Fasting lipid profile
- Creatinine and GFR
- Urinalysis
- Microalbumin-to-creatinine ratio
- Thyroid-stimulating hormone with free T₄
- Periodic measurement of vitamin B₁₂ levels for patients on long-term metformin therapy
especially those with anemia or peripheral neuropathy

**TREATMENT**

- Therapeutic lifestyle modification to include physical activity focused on weight loss and medical nutrition therapy (preferably via a registered dietitian).
- Mediterranean diet and diets high in fiber-rich foods such as vegetables, fruits, whole grains, seeds, and nuts plus white meat sources are protective against type 2 diabetes (6)[B].
- Consider referring patients with prediabetes to an intensive diet and physical activity behavioral counseling program adhering to the tenets of the Diabetes Prevention Program targeting a loss of 7% of body weight and to increase their moderate-intensity physical activity (such as brisk walking to at least 150 min/week) (6)[A].
- Resistance training and endurance exercise both reduce diabetes risk.
- Interrupt prolonged sitting every 30 minutes with short bouts of physical activity (6)[B].
- Diabetes prevention programs are cost-effective and often covered by third-party payers (6)[B].
- Screen and treat modifiable risk factors for cardiovascular disease (6)[B].
- Diabetes self-management education and support systems are appropriate venues for people with prediabetes to receive education and support to develop and maintain behaviors that can prevent or delay the onset of diabetes (6)[B].
- Technology-assisted tools including Internet-based social networks, distance learning, DVD-based content, and mobile applications can be useful elements of effective lifestyle modification to prevent diabetes (6)[B].

**MEDICATION**

Consider metformin therapy for prevention of type 2 diabetes, especially in those with BMI >35, those ages <60 years, and women with prior GDM and/or rising HbA1c despite lifestyle intervention (6)[C].

**First Line**

Metformin (drug of choice): started at 500 mg BID or 500 mg XR. Observational data suggest it can be used safely down to GFR of 30 to 45 but may require dose adjustments.

**Second Line**

Acarbose: started at 50 mg PO once daily and titrated to 100 mg PO TID; GI upset is common.

**ISSUES FOR REFERRAL**

- Nutritionist
- Diabetes educator/registered dietitian upon diagnosis
- Exercise physiologist
- Lifestyle coaching

**ADDITIONAL THERAPIES**

Alternative/botanical therapy:

- Although studies lack large sample size and ideal design, there is some evidence that fenugreek, bitter melon, and cinnamon can reduce hyperglycemia and improve insulin sensitivity (7).
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- At least annual monitoring for development of diabetes with HbA1c, 2-hour OGTT, or fasting glucose
- BP should be routinely measured.
- Annual testing for lipid abnormalities and microalbuminuria (for detection and therapy modification of incipient diabetic nephropathy)
- Monitoring of BMI

DIET
- Mediterranean diet has been shown to be beneficial. One small cohort study showed that the addition of about 10 g of extra virgin olive oil to meals improved postprandial glucose by reducing DPP4 activity and increasing insulin and GLP-1. It also showed a significant decrease in TG and apolipoprotein B-48.
- Limit high glycemic carbohydrates and sucrose-containing foods.
- Diets high in fiber, vegetables, nuts, seeds, and whole grains

PROGNOSIS
- Individuals with IFG and/or IGT have high risk for the future development of diabetes.
- Prediabetes increases the risk of developing type 2 diabetes, heart disease, and stroke.
- 20–70% of individuals with prediabetes who do not lose weight, change their dietary habits, and/or engage in moderate physical activity will progress to type 2 diabetes within 3 to 6 years.
- Lifestyle intervention reduced 3-year diabetes incidence by 58% compared to 31% with metformin.

COMPLICATIONS
- Cardiovascular disease
- Peripheral artery disease
- Stroke: 2 to 4 times higher risk
- Ketoacidosis
- Sexual dysfunction
- Gastroparesis
- Nephropathy and potential for renal failure
- Retinopathy and potential for loss of vision
- Peripheral and autonomic neuropathy

REFERENCES

ADDITIONAL READING

CODES

ICD10
- E74.39 Other disorders of intestinal carbohydrate absorption
- R73.09 Other abnormal glucose
- R73.01 Impaired fasting glucose

CLINICAL PEARLS

- Patient education and lifestyle reinforcement should be emphasized in all clinical encounters as lifestyle optimization is essential for all patients with prediabetes.
- Research shows that you can lower your risk for type 2 diabetes by 58% by losing 7% of your body weight (or 15 lbs if you weigh 200 lbs).
- Recommend exercising moderately (such as brisk walking) 30 min/day, 5 days a week.
- Consider concurrent cardiovascular risks and further workup as indicated clinically.
**GONOCOCCAL INFECTIONS**
Melissa Jefferis, MD, FAAFP

### BASICS

#### DESCRIPTION
A sexually or vertically transmitted bacterial infection caused by Neisseria gonorrhoeae:
- **N. gonorrhoeae** is a fastidious gram-negative intracellular diplococcus (1)[A].
- Presents as conjunctival, pharyngeal, urogenital, or anorectal infection. Urogenital infections are the most common (1)[A].
- Hematogenous dissemination leads to fever, cutaneous lesions, arthralgias, purulent or sterile arthritis, tenosynovitis, endocarditis, or (rarely) meningitis (1)[A].
- Asymptomatic carrier states occur in men and women
- In newborns of infected mothers, gonococcal ophthalmia neonatorum, a purulent conjunctivitis, may occur after vaginal delivery. Can lead to potential blindness if not treated promptly (1,2)[A].
- System(s) affected: cardiovascular, musculoskeletal, nervous, reproductive, skin/exocrine
- Synonym(s): gonococcal infection; clap

#### EPIDEMIOLOGY
- Predominant age: 15- to 44-year-olds account for 92% of cases; highest rate among those ages 20 to 24 years
- Predominant sex: Men 213/100,000; Women 146/100,000

**Incidence**
Centers for Disease Control and Prevention (CDC) 2018: 583,405 reported cases

**Prevalence**
Incidence and prevalence are roughly equal. The true prevalence is higher due to asymptomatic cases (2)[A]:
- Rates peaked in mid-1970s and fell 74% over the next 20 years with national control program. Rates have been slowly increasing since 2012 (2)[A].
- Rates in men now higher than women (2)[A].

#### ETIOLOGY AND PATHOPHYSIOLOGY
Infection requires four steps: (i) mucosal attachment—bacterial proteins bind to receptors on host cells, (ii) local penetration/invasion, (iii) local proliferation, (iv) inflammatory response or dissemination. N. gonorrhoeae spreads most commonly through sexual contact.

#### Genetics
Deficiency of late components of complement cascade (C7–C9) predisposes to disseminated disease.

#### RISK FACTORS
- History of previous gonorrhea infection or other STIs
- Sexual exposure to an infected individual without appropriate use of barrier protection (condom)
● New/multiple sexual partners
● Inconsistent condom use
● Commercial sex work or drug use
● Infants: infected mother
● Children: sexual abuse by infected individual
● Autoinoculation (finger to eye)

GENERAL PREVENTION
● Condoms offer partial protection and must be used appropriately during oral, anal, and vaginal
  sex.
  - Treat sexual contacts; consider expedited partner therapy (EPT) (2)[A].

COMMONLY ASSOCIATED CONDITIONS
Other STIs: Chlamydia, syphilis, HIV, hepatitis B, herpes (2,3)[A]

DIAGNOSIS

HISTORY
● Sexual history
  - Number of partners; age of onset of sexual activity; STI history
  - New/recent change in sexual partners
  - Contact with commercial sex workers
  - Condom use
  - Menses and possibility of pregnancy
  - 10% of men and 20–40% of women are asymptomatic (2)[A].
  - If symptomatic, explore onset, context, duration, timing, severity, and associated symptoms:
    - Symptoms (when present) typically appear within 1 to 14 days after exposure (1)[A].
    - Ocular symptoms: discharge, itch, redness (1)[A]
    - Pharyngeal symptoms: asymptomatic infection (98%), sore throat (1)[A]
    - GI symptoms: acute diarrhea (1)[A]
    - Urinary symptoms: frequency, urgency, dysuria (1)[A]
    - Urethral symptoms: discharge (1,2)[A]
      - Males: scant to copious purulent urethral discharge (82%), dysuria (53%), asymptomatic
        (10%), testicular pain (1%), proctitis
      - Females: endocervical discharge (96%), asymptomatic cervical infection (20%), vaginal
        discharge, Bartholin gland swelling, dysmenorrhea, menometrorrhagia, abdominal
        pain/tenderness, dyspareunia, cervical motion tenderness, rebound, infertility, chronic
        pelvic pain
    - Either sex, with receptive anal intercourse: rectal discharge, tenesmus, rectal burning; can also
      be asymptomatic
    - Disseminated syndromes (1,2)[A]
      - Fever, chills, malaise, skin rash, arthralgia/arthritis
      - Endocarditis: high fevers
      - Meningitis: meningeal signs, headache, skin lesions, fever, altered mental status

PHYSICAL EXAM
General: fever, chills (1)[A]
Ocular: purulent discharge, conjunctivitis, chemosis, eyelid edema, corneal ulceration (1)[A]
Pharynx: exudative pharyngitis (<1%) (1)[A]
GI: acute diarrhea, hyperactive bowel sounds (1)[A]
Genitourinary (GU) (1)[A]
  – Males: urethral discharge, testicular tenderness
  – Females: endocervical discharge, Bartholin gland abscess, abdominal pain/tenderness, cervical motion tenderness, rebound tenderness
Either sex, for receptive anal intercourse: rectal discharge; rectal exam may be normal (1)[A].
Disseminated syndromes (1)[A]:
  – Fever, chills, malaise, tenosynovitis, maculopapular–pustular rash, polyarthralgia—typically large joints (knee, wrist, ankle), purulent arthritis
  – Endocarditis: rapid cardiac valve destruction, heart murmurs, high fevers
  – Meningitis: meningeal signs, headache, skin lesions, fever, altered mental status

DIFFERENTIAL DIAGNOSIS
Chlamydia trachomatis, UTIs, other vaginitis, or urethritis (bacterial, viral, or parasitic)

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
  – Nucleic acid amplification test (NAAT) is the most sensitive and specific test for N. gonorrhoeae (2)[A].
  – Other options:
    – Genital culture
    – Add pharyngeal culture in adolescents.
    – Gram stain (recommended for urethritis)
    – Urethral smear, sensitivity in symptomatic male: ≥95%; sensitivity of endocervical smear in infected woman: 40–60%; specificity: 100%
  – DNA probes and polymerase chain reaction (PCR) sensitivity: 92–99% dependent on population; specificity: >97%; can replace culture
  – Blood culture is 50% sensitive in disseminated disease. Joint fluid culture is 50% sensitive in septic arthritis. Screen for additional STIs, especially chlamydia, syphilis, and HIV.
  – Imaging is not generally recommended.

Follow-Up Tests & Special Considerations
Test of cure not generally recommended, except for (1,2)[A]:
  – Individuals treated for pharyngeal gonorrhea with an alternative antibiotic regimen should have test of cure 14 days after treatment with NAAT or culture (2)[A].
  – Consider follow-up testing in cases of recurrent infection, when oral cephalosporin treatment is used, and/or in areas with high antibiotic resistance (2)[A].

Diagnostic Procedures/Other
Culdocentesis may demonstrate free purulent exudate and provide material for Gram staining and culture. Gram staining material from unroofed skin lesions may show typical organisms. Pelvic ultrasound or CT scan may demonstrate thick, dilated fallopian tubes or abscess formation.

Test Interpretation
Gram-negative intracellular diplococci
Nonpathologic gram-negative diplococci may be found in extragenital locations. For this reason, Gram stain of pharyngeal or rectal swabs is not recommended.

TREATMENT

GENERAL MEASURES
- STI counseling and condom use
- In children and adolescents, suspect sexual abuse.

MEDICATION
- N. gonorrhoeae multidrug antimicrobial resistance continues to increase. CDC recommends dual therapy (treat for chlamydia and drug-resistant strains) (2,3,4)[A].
- Quinolones are not recommended (2,4)[A].
- If treatment fails, check culture and sensitivities and report to CDC through local health authorities (2,3)[A].
- Treat with regimen that is also effective against uncomplicated genital chlamydial infection (2,3,4)[A].

First Line
- Uncomplicated urogenital, anorectal, and pharyngeal gonorrheal infection (2)[A]
  - Ceftriaxone 250 mg IM in a single dose PLUS
  - azithromycin 1 g PO single dose; ideally administered together on the same day, preferably under direct observation
  - Azithromycin is the preferred second drug over doxycycline due to ease of administration and increased resistance to tetracycline.
  - Alternative: cefixime 400 mg PO once PLUS azithromycin 1 g PO once
- Pharyngitis: ceftriaxone 250 mg IM once PLUS treatment for chlamydia (azithromycin 1 g PO once) (1,2)[A]
- Conjunctivitis: ceftriaxone, 1 g IM single dose PLUS azithromycin 1 g PO once (1,2)[A]
- Arthritis and arthritis–dermatitis syndrome (1,2)[A]
  - Ceftriaxone 1 g IM or IV q24h until 24 to 48 hours after improvement begins to complete at least 1 week of antibiotic treatment, PLUS azithromycin 1 g PO once
  - Alternative regimens:
    o Cefotaxime 1 g IV every 8 hours until 24 to 48 hours after improvement begins to complete at least 1 week of antibiotic treatment, PLUS azithromycin 1 g PO once
    o Ceftizoxime 1 g IV every 8 hours until 24 to 48 hours after improvement begins to complete at least 1 week of antibiotic treatment, PLUS azithromycin 1 g PO once
- Meningitis and endocarditis (1,2)[A]
  - Ceftriaxone 1 to 2 g IV q12h 10 to 14 days for meningitis; 4 weeks for endocarditis PLUS azithromycin 1 g PO once
- Contraindications: Doxycycline is contraindicated in pregnancy and young children.

Pediatric Considerations
- Children >45 kg: same dosing as adults (1,2)[A]
- Children <45 kg: uncomplicated urethral, cervical, rectal, or pharyngeal gonococcal infections
Ceftriaxone 125 mg IM in single dose
- Disseminated infections: ceftriaxone 50 mg/kg IV or IM daily (max dose 1 g) in single dose; bacteremia: 7 days; meningitis: 10 to 14 days; endocarditis: 4 weeks

- Ophthalmic neonatorum prophylaxis: single application of erythromycin 0.5% ophthalmic ointment to each eye immediately after delivery (1,2)[A]
- Neonatal conjunctivitis: ceftriaxone 25 to 50 mg/kg IV or IM in a single dose (not to exceed 125 mg) (1,2)[A]
- Conjunctival exudates should be cultured for definitive diagnosis (1,2)[A].
- Scalp abscesses (from scalp electrodes) (1,2)[A]
  - Ceftriaxone 25 to 50 mg/kg/day IV or IM in a single daily dose for 7 days. Treat for a duration of 10 to 14 days if meningitis is documented.
- Asymptomatic infants born to mothers with untreated gonorrhea (1,2)[A]
  - Ceftriaxone 25 to 50 mg/kg IV or IM, not to exceed 125 mg in a single dose

**Pregnancy Considerations**
- Pregnant women should be treated with dual therapy including ceftriaxone 250 mg IM once AND azithromycin 1 g PO once (2)[A].
- Alternative: gentamicin 240 mg IM once PLUS azithromycin 2 g PO once (4)[A]
- Another alternative includes treatment with spectinomycin. If spectinomycin or other regimens are not possible, consultation with an infectious disease specialist is recommended (2)[A].
- Test of cure generally not recommended if uncomplicated urogenital or rectal infections are treated with recommended/alternative regimens

**Second Line**
- Due to antimicrobial resistance, combination therapy using two agents with different mechanisms of action improves treatment efficacy and decreases resistance to cephalosporins (1,2)[A].
- A single 2-g oral dose of azithromycin has been used in the past, although should be avoided due to the potential to develop macrolide resistance (2)[A].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Hematogenously disseminated infection
- Pneumonia or eye infection in infants

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- U.S. Preventive Services Task Force (USPSTF) (5)[A]
  - Screen all sexually active women 24 years of age and younger and in older women at increased risk for infection for chlamydia and gonorrhea: grade B recommendation.
  - Insufficient evidence to recommend for or against screening for chlamydia and gonorrhea in men: grade I recommendation
– Report cases of gonorrhea to public health (3,5)[A].

CDC
– Screen annually for sexually active men who have sex with men (MSM) at sites of contact (urethra, rectum, pharynx), regardless of condom use. Increase screening to every 3 to 6 months if at increased risk.

PATIENT EDUCATION
– Counseling concerning risk reduction, condom use, future fertility, and full STI testing
– Encourage patient to notify partners (from past 60 days); consider EPT.

PROGNOSIS
Complete cure with return to normal function with adequate and timely treatment

COMPLICATIONS
– Infertility
– Urethral stricture
– Corneal scarring
– Destruction of joint articular surfaces
– Cardiac valvular damage

Pediatric Considerations
Vertical transmission is a significant risk among patients with gonococcal infection at the time of delivery (1,2)[A].

REFERENCES

SEE ALSO
Chlamydia Infection (Sexually Transmitted); HIV/AIDS; Pelvic Inflammatory Disease; Syphilis

CODES

ICD-60
ICD10
- A54.9 Gonococcal infection, unspecified
- A54.03 Gonococcal cervicitis, unspecified
- A54.31 Gonococcal conjunctivitis

CLINICAL PEARLS
- Antibiotic resistance is a significant problem
- Treatment for uncomplicated gonorrhea should include two drugs, one of which is effective against chlamydia.
- Screen patients with gonorrhea for chlamydia, syphilis, HIV, and hepatitis.
GOUT
David A. Ross, MD, CAQSM

BASICS

DESCRIPTION
- Gout is an inflammatory arthritis characterized by deposition of monosodium urate (MSU) crystals that accumulate in joints and soft tissues, resulting in acute and chronic arthritis, soft-tissue masses called tophi, urate nephropathy, and uric acid nephrolithiasis.
- Acute gouty arthritis can affect ≥1 joint; the 1st metatarsophalangeal joint is most commonly involved at presentation (podagra).
- Gout is related to a hyperuricemia (serum uric acid level >6.8 mg/dL) (1)[C] and although hyperuricemia is necessary for the development of gout, it is not the only determining factor.
- After an initial flare, a second flare occurs in ~60% of patients within 1 year and 78% within 2 years of the initial attack (2)[C].
- Management involves treating acute attacks and preventing recurrent disease by long-term reduction of serum uric acid levels through pharmacology and lifestyle adjustments.

EPIDEMIOLOGY

Incidence
- The incidence and prevalence of gout has been increasing over the past several decades (3).
- Gout has a higher incidence in males than females.

Prevalence
- Overall prevalence of gout is 3.9% (8.3 million people) in the United States in 2008 (3):
  - Men 5.8% (6.1 million)
  - Women 2.0% (2.2 million)
- Prevalence increases with age and serum uric acid levels.

ETIOLOGY AND PATHOPHYSIOLOGY
- Hyperuricemia results from uric acid overproduction, underexcretion, or often a combination of the two.
- Gout occurs when MSU, a product of purine metabolism, precipitates out of solution and accumulates in joints and soft tissues.
- Transient changes in uric acid solubility caused by local temperature decrease, trauma, or acidosis may lead to an acute gouty attack.
- Uric acid crystals that precipitate can trigger an immune response and inflammation in the affected joint.
- Left untreated, this crystal deposition leads to permanent joint damage and tophus formation.
- Obesity predisposes to gout by promoting insulin resistance, which in turn reduces renal uric acid excretion resulting in hyperuricemia (4)[A].
- Hypertension and renal disease reduce renal uric acid excretion due to glomerular arteriolar damage (4)[A].

Genetics
- Phosphoribosyl pyrophosphate (PRPP) deficiency and hypoxanthine guanine
phosphoribosyltransferase (HGPRT) deficiency (Lesch-Nyhan syndrome) are inherited enzyme defects associated with overproduction of uric acid.

- Polymorphisms in the URAT1 and SLC2A9 (GLUT9) renal transporters are hereditary enzyme defects resulting in primary underexcretion of uric acid

**RISK FACTORS**

- Age >40 years
- Male gender
- Increased purine uptake (meats and seafood)
- Alcohol intake (especially beer)
- Obesity (BMI >30)
- Heart disease and congestive heart failure
- Dyslipidemia
- Hypertension and renal disease
- Smoking
- Diabetes mellitus
- Diuretics raise serum uric acid levels by increasing uric acid reabsorption and decreasing uric acid secretion in the kidneys ([4][A]).
- Urate-elevating medications:
  - Thiazide diuretics: ethambutol
  - Loop diuretics (less of a risk vs. thiazides)
  - Niacin
  - Calcineurin inhibitors (cyclosporine and tacrolimus)

**GENERAL PREVENTION**

- Maintain optimal weight
- Regular exercise
- Diet modification (purine-rich foods)
- Reduce alcohol consumption (beer and liquor)
- Smoking cessation
- Maintain fluid intake and avoid dehydration

**COMMONLY ASSOCIATED CONDITIONS**

- Hypertension
- Dyslipidemia
- Nontraumatic joint disorders
- Heart disease
- Diabetes mellitus
- Metabolic syndrome
- Obesity (BMI >30)
- Renal disease

**DIAGNOSIS**

**HISTORY**

- Classic presentation of acute gouty arthritis:
  - Intense pain and tenderness in the 1st metatarsophalangeal joint (podagra)
— Can occur in the midtarsal, ankle, or knee joints
— Joint may be swollen, warm, and erythematous.
— Often awakens patients from sleep due to an intolerance to contact with clothing or bed sheets
— There is a rapid onset of intense pain, often beginning in the early morning and progressing rapidly over 12 to 24 hours.
— In the absence of treatment, flares can last up to 10 days.
  ● Fever can be present.
  ● Subcutaneous or intraosseous nodules, referred to as tophi, can be seen.
  ● Pain with urination secondary to uric acid renal stones

**PHYSICAL EXAM**

  ● Examine suspected joint(s) for tenderness, swelling, and range of motion (ROM).
  ● Assess for presence of firm nodules known as tophi
  ● In patients with chronic gout, tophi can frequently be found in the helix of the ear, over the olecranon process, or on the Achilles tendon.
  ● Patients with untreated chronic gout can have evidence of joint inflammation and deformity.

**DIFFERENTIAL DIAGNOSIS**

Bursitis, tendonitis, septic arthritis, pseudogout (calcium pyrophosphate deposition disease), cellulitis, osteoarthritis

**DIAGNOSTIC TESTS & INTERPRETATION**

  ● Serum uric acid (may be normal during an acute flare)
  ● CBC (can see elevation of WBC during gout flare)
  ● Synovial fluid analysis: urate crystals (negatively birefringent under polarizing microscopy), cell count (WBC usually 2,000 to 5,000 cells/mm³); culture to rule out infection
  ● Screen for uric acid overproduction using 24-hour urinary uric acid in those patients with gout onset before the age of 25 years or with a history of urolithiasis [1][C].
  ● Radiographs are normal early in disease but can reveal
    — Swelling in acute gout
    — Periarticular erosions with periosteum overgrowth in chronic gout
  ● Urate kidney stones are radiolucent and thus invisible on radiograph.
  ● Ultrasound evidence of urate deposition—hyperechoic enhancement over surface of hyaline cartilage
  ● Dual energy CT (DECT) imaging can show urate deposition at articular or periarticular sites.

**TREATMENT**

**GENERAL MEASURES**

Topical ice or cold pack as needed [5][B]

**MEDICATION**

  ● Acute treatment
    — General principles:
      o Acute gouty arthritis attacks should be treated with pharmacologic therapy [5][C].
      o Pharmacologic treatment should be initiated within 24 hours of acute gout attack [5][C].
Ongoing pharmacologic urate-lowering therapy should not be interrupted during an acute gout attack (5)[C].
- Choice of agent is based on severity of pain and the number of joints involved (5)[C].
  - Mild/moderate gout severity (≤6 of 10 on visual analog pain scale, particularly for an attack involving only one or a few small joints or one to two large joints)
- NSAIDs:
  - Naproxen (Naprosyn, Anaprox, Aleve): 750 mg followed by 250 mg q8h for 5 to 8 days (5)[C]
  - Indomethacin (Indocin): 50 to 150 mg/day for 2 to 7 days (5)[C]
  - Ibuprofen (Advil): 800mg q8h for 5 to 7 days (5)[C]
  - Celecoxib (Celebrex)
    - Not FDA-approved but can be considered in selected patients with contraindications or intolerance to NSAIDs (5)[C]
    - Dose: 800 mg once, then 400 mg on day 1, and then 400 mg BID for 1 week (5)[C]
- Corticosteroids:
  - Those with an acute flare involving one to two large joints can consider intra-articular corticosteroids; can consider using oral corticosteroids in combination
  - Corticosteroids are useful in patients with acute gout flare who cannot tolerate NSAIDs or have contraindications to NSAIDs such as chronic kidney disease (CKD).
  - For other acute flares, use oral corticosteroids:
    - Prednisone (Sterapred): 0.5 mg/kg/day for 5 to 10 days followed by discontinuation or alternately 2 to 5 days at full dose followed by tapering for 7 to 10 days and then discontinuing (5)[C]
    - Methylprednisolone (Medrol) dose pack (5)[C]
    - Triamcinolone acetonide (Trivaris): 60 mg IM single dose followed by oral corticosteroids (5)[C]
- Colchicine (Colcrys):
  - Used for gout attacks where the onset was <36 hours prior to treatment initiation (5)[C]
  - Begin a loading dose of 1.2 mg followed by 0.6 mg 1 hour later, followed by 0.6 mg once or twice daily 12 hours later, until the gout attack resolves (5)[C].
  - Dose reduction recommended in moderate to severe kidney disease and in those on inhibitors of cytochrome P450 3A4 and P-glycoprotein (clarithromycin, erythromycin, cyclosporine (5)[C].
- Severe gout (≥7 of 10 on visual analog pain scale, involving ≥4 joints with arthritis involving ≥1 region, or involving three separate large joints)
- Initial combination therapy is an option and includes the use of full doses of the following (5)[C]:
  - Colchicine and NSAIDs
  - PO corticosteroids and colchicine
  - Intra-articular steroids
- For patients not responding to initial pharmacologic monotherapy, add a second agent (5)[C].
- Chronic treatment
  - Indications for pharmacologic urate-lowering therapy include any patient with
    - Tophus or tophi by clinical exam or imaging study (1)[C]
    - Frequent attacks of acute gouty arthritis (≥2 attacks per year) (1)[C]
- CKD stage 2 or worse (1)[C]
- Past urolithiasis (1)[C]
  - Treat to the serum uric acid:
    - Minimum serum uric acid target is <6 mg/dL
    - Serum uric acid target may need to be <5 mg/dL to improve gout signs and symptoms (1)[C].
  - Urate-lowering agents can be prescribed during an acute attack provided that effective anti-inflammatory prophylaxis has been initiated prior to urate-lowering therapy (1)[C].
  - Anti-inflammatory prophylaxis required when initiating urate-lowering therapy:
    - First line
      - Low-dose colchicine: 0.6 mg once or twice daily (5)[C]
      - Low-dose NSAIDs: naproxen 250 mg PO BID (5)[C]
    - Second line: if use of colchicine and NSAIDs both are not tolerated, contraindicated, or ineffective:
      - Low-dose prednisone or prednisolone at ≤10 mg/day (5)[C]
    - Treatment duration for the greater of
      - At least 6 months (5)[C] or
      - 3 months after achieving serum urate appropriate for the patient with no tophi on exam (5)[C], or for 6 months after achieving serum urate appropriate for the patient with ≥1 tophi on exam (5)[C]
- Pharmacologic urate-lowering agents:
  - Allopurinol (Zyloprim, Aloprim): xanthine oxidase inhibitor (1)[C]
    - Starting dose should be no higher than 100 mg/day (1)[C].
    - Starting dose should be 50 mg/day in stage 4 CKD or worse.
    - Gradually titrate the dose upward q2–5wk to appropriate maximum dose (1)[C].
    - Dose can be >300 mg/day, even with renal impairment, as long as accompanied by patient education and monitoring of drug toxicity; maximum FDA-approved dosage is 800 mg/day (1)[C].
    - Regularly monitor for allopurinol hypersensitivity syndrome (AHS), pruritus, rash, elevated hepatic transaminases, and eosinophilia.
    - Screening for the HLA-B*5801 allele for AHS should be performed in those of Korean descent with stage 3 CKD or worse and Chinese or Thai descent irrespective of renal function (1)[C].
  - Febuxostat (Uloric): selective xanthine oxidase inhibitor (1)[C]
    - No renal or hepatic adjustments needed for mild-to-moderate hepatic or renal disease
    - Starting dose 40 mg/day; may be titrated to 80 mg/day
    - In select instances, may dose up to 120 mg/day (not FDA-approved) (1)[C]
  - Probenecid: uricosuric agent (1)[C]
    - Alternative first-line urate-lowering therapy; use if xanthine oxidase inhibitor is contraindicated or not tolerated (1)[C].
    - May be used in addition to allopurinol or febuxostat if serum urate target not achieved
    - Multiple drug interactions exist as well as risk of urolithiasis with this agent.
    - Not recommended if creatinine clearance (CrCl) is <50 or with patient history of urolithiasis (1)[C]
    - Starting dose is 250 mg BID; gradually titrate to 2,000 mg/day.

ADDITIONAL THERAPIES
Other treatment

- Losartan possesses uricosuric properties; therefore, it may be an excellent agent if patient is also hypertensive.
- Acute treatment: adrenocorticotropic hormone (ACTH): 25 to 40 IU subcutaneously (5)[C]
- Pegloticase in select severe instances

**SURGERY/OTHER PROCEDURES**
Large tophi that are infected or interfering with joint motion may need to be surgically removed.

---

**ONGOING CARE**
Recommended regular follow-up with primary care physician or rheumatologist during acute gout flare

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Serum uric acid measurements q2–5wk while titrating urate-lowering treatment to goal (1)[C]
- Regularly monitor CBC, renal function, liver function test, and urinalysis.

**DIET**
- General lack of evidence regarding specific recommendations, although the American College of Rheumatology has outlined the following (1)[C]:
  - General measures:
    - Weight loss for obese patients
    - Healthy diet and good hydration
    - Smoking cessation
  - Avoid
    - Organ meats high in purine content (sweetbreads, liver, kidney) (1)[C]
    - High-fructose corn syrup–sweetened sodas, other beverages, or foods
    - Alcohol overuse (>2 servings per day for men and >1 serving per day for women) (1)[C]
    - Alcohol use, especially during periods of frequent gout attacks or advanced gout under poor control
  - Limit
    - Beef, lamb, pork, and seafood with high purine content such as sardines and shellfish (1)[C]
    - Servings of naturally sweetened fruit juices
    - Sugar, sweetened beverages, and desserts
    - Table salt, including in sauces and gravies
    - Alcohol (particularly beer) in all patients (1)[C]
  - Encourage
    - Low-fat or nonfat dairy products
    - Vegetables

**PATIENT EDUCATION**
- Dietary and lifestyle modifications (1)[C]
- Instructions on initiating treatment on signs and symptoms of an acute gout attack without the need to consult health care provider for each attack (1)[C]
- Discussion that gout is caused by excess uric acid and that effective urate-lowering therapy is
essential treatment (1)[C]

**PROGNOSIS**
Gout can usually be successfully managed with proper treatment.

**COMPLICATIONS**
- Increased susceptibility to infection
- Inflammatory arthritis and joint destruction
- Uric acid nephropathy and renal stones

**REFERENCES**

**ADDITIONAL READING**

**CODES**
**ICD10**
- M10.9 Gout, unspecified
- M10.00 Idiopathic gout, unspecified site
- M10.30 Gout due to renal impairment, unspecified site

**CLINICAL PEARLS**
- Monosodium urate crystals found in synovial fluid aspirate are pathognomonic for gout.
- Pharmacologic treatment should begin within 24 hours of acute gout flare.
- Asymptomatic hyperuricemia does not require treatment.
GRANULOMA ANNULARE
Stephen C. Sears, DO ● Adam K. Saperstein, MD

BASICS

DESCRIPTION
Granuloma annulare (GA) is a benign skin condition characterized by groups of skin-colored to erythematous papules that are usually in an annular (ring-like) pattern and typically located on the dorsal aspects of the hands and feet. There are five types of GA: localized, generalized, subcutaneous, patch, and perforating.

EPIDEMIOLOGY
Incidence
- GA is a relatively common, noninfectious granulomatous disease. Population-based studies to determine the incidence and/or prevalence of GA are lacking. A single study in 1980 demonstrated that 0.1–0.4% of new patients presenting to dermatologists have GA but did not report similar descriptive statistics in the primary care arena (1).
- Although most lesions resolve spontaneously within 2 years, some persist for 10 years or more.
- Predominant sex: female > male (1 to 2.5:1)
- Onset of symptoms occurs at <30 years old in 2/3 of all patients. Typical ages for onset of each subtype are:
  - Localized: <30 years old
  - Generalized: bimodal: <10 years old, 30 to 60 years old
  - Subcutaneous: 2 to 14 years old
  - Patch: >30 years old
  - Perforating: children and young adults
- Distribution of subtypes:
  - Localized: 75%
  - Generalized: 10–15%
  - Subcutaneous: <5%
  - Patch type: <5%
  - Perforating: <5%

ETIOLOGY AND PATHOPHYSIOLOGY
The etiology of GA remains unknown. It is hypothesized to be a dermatologic manifestation of a delayed-type hypersensitivity reaction to an unknown antigen in the derm, mediated by tumor necrosis factor alpha (TNF-α) and interleukin factors 1 and 2 (IL-1 and IL-2) (2). Characteristic histopathologic features include lymphohistiocytic infiltrates, degeneration of collagen, palisading or interstitial granulomatous inflammation, and mucin deposition.

Genetics
There is some evidence for a genetic predisposition. Two studies reported an increased frequency of HLA-Bw35 in patients with generalized GA. Of note, HLA-Bw35 has also been associated with thyroid disease (1).

RISK FACTORS
No definite risk factors have been identified. There are reported associations between GA and diabetes mellitus (DM), autoimmune thyroid disease, dyslipidemia, human immunodeficiency virus, Epstein-Barr virus, herpes simplex virus, systemic lupus erythematosus, tuberculosis, and hepatitis B and C, among others. There have also been associations with interferon-α therapy, trauma, sun exposure, insect bites, borreliosis, and malignancies (most commonly lymphoma) (2,3).

**GENERAL PREVENTION**
There are no known preventive measures for GA.

**COMMONLY ASSOCIATED CONDITIONS**
- **DM:** The association between GA and DM is controversial. Early studies from the 1980s showed a possible link, but recent case-controlled studies have shown no statistically significant association between GA and DM (3).
- **Autoimmune thyroid disease:** Multiple case reports have linked thyroid disease with both generalized and localized GA. In one case-control study, 24 women with localized GA were compared to 100 age-matched women with non-GA dermatologic disease. A statistically significant increase in the incidence of autoimmune thyroid disease among those with localized GA as compared with those with other non-GA cutaneous disease was identified (12% vs. 1%, p = .022) (2,3).
- **Malignancy:** There is no definitive relationship between GA and malignancy. A review of the literature found 14 case reports and two correlation studies in which patients who had one or more malignancies also had GA. In a majority of these cases, the malignancies were hematologic, primarily lymphoma (2,3).
- **Dyslipidemia:** Dyslipidemia may be associated with GA. A single case-control study (n = 140) demonstrated a statistically significant increase in hyperlipidemia among patients with GA compared to controls (79.3% vs. 51.9%, p<.001) (4).
- **HIV:** Among patients with GA, those who also have HIV appear more likely to have the generalized subtype. In one study of 34 patients with GA and HIV, 20 (59%) had generalized GA (2).
- **Note:** Conclusions regarding associations between GA and various diseases, including those listed above, are limited by both design and power. Consequently, in the absence of new research, definitive associations between GA and other diseases cannot be made.

**DIAGNOSIS**

**HISTORY**
Cutaneous lesions of GA are generally asymptomatic. Lesions often persist for months or years, especially in patients who have generalized GA. In most cases, regardless of subtype, GA resolves spontaneously but may thereafter recur without obvious trigger.

**PHYSICAL EXAM**
- **Localized:** asymptomatic, flesh-colored or erythematous annular, or arciform plaque with a moderately firm, rope-like border and central clearing, ranging from 5 mm to 5 cm in diameter. Small 1- to 2-mm papules may be noted peripheral to the primary lesion. The most common locations are the dorsal aspects of the distal upper and lower extremities; involvement of palms is rare. It is common to have multiple lesions at the time of presentation.
Generalized: Lesions have the same morphology as localized GA lesions, but tend to be larger, greater in number (usually >10), persist for a longer period of time, and are more widespread.

Subcutaneous: firm, nontender nodules that tend to grow rapidly; usually solitary but may occur in groups; most common location is scalp and/or anterior aspect of the lower extremities, followed by upper extremities and buttocks.

Patch: erythematous macules and patches distributed symmetrically on the extremities and trunk. The typical annular configuration may or may not be present; often involves proximal extremities

Perforating: Damaged collagen from dermis is extruded onto skin surface. Papules may be up to 4 mm in diameter and display yellowish umbilication, crusting, or scale. Lesions are often widely distributed on the body and cause scarring.

DIFFERENTIAL DIAGNOSIS

Localized: tinea corporis, annular lichen planus, necrobiosis lipoidica, pityriasis rosea, erythema migrans, leprosy

Generalized: sarcoidosis, lichen planus, cutaneous metastases, mycosis fungoides (cutaneous T-cell lymphoma)

Patch type: erythema migrans

Subcutaneous: rheumatoid nodules

Perforating: molluscum contagiosum, sarcoidosis, insect bites

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Diagnosis is typically established by history and physical examination; laboratory investigations are rarely needed. Microscopic evaluation of skin cells using potassium hydroxide (KOH) preparation may be useful to exclude a fungal process.

Consider laboratory testing to evaluate comorbid dyslipidemia, DM, thyroid disease, HIV, hepatitis B/C, and malignancy as clinically indicated.

Diagnostic Procedures/Other

Punch biopsy and histologic evaluation may aid in confirming the diagnosis and identifying the subtype. Immunohistochemical streptavidin–biotin–horseradish peroxidase (HRP) analysis for CD68/KP-1 (a marker for histiocytic differentiation) may also aid in the diagnosis.

Test Interpretation

Dermal infiltrate demonstrating foci of degenerative collagen associated with palisading granulomas around an anuclear dermis with mucin deposition. Histologic variants include interstitial (histiocytic infiltrate between collagen fibers), classic (palisading dermal granulomas), and epithelioid (tuberculoid and sarcoidal granulomas).

TREATMENT

GENERAL MEASURES

GA is a self-limited condition that is likely to regress spontaneously. The clinician’s primary role after making the diagnosis is to educate the patient about the natural history of GA and to consider screening for conditions that may be associated with this disease.
MEDICATION
- Strength of recommendation for therapeutic interventions is B or C (3,5).
- The trauma induced by biopsy alone can cause involution of lesions through an unknown mechanism.
- Given the self-limited nature of the disease, it is incumbent on providers to assess the risk/benefit ratio of treatment. Reassurance is often all that is required for localized, asymptomatic disease.
- The following therapies have been tried with variable success (2,3,5,6). Duration of therapy is often undefined and is based on clinical response.

First Line
Corticosteroids
- High-potency topical (class I or II), with or without occlusion (3)[C],(5)[C]
- Intralesional triamcinolone: concentration of 2.5 to 5.0 mg/mL (3)[C],(5)[C]. Technique: Insert the needle into the dermis at the elevated border and slowly inject while withdrawing the needle, with enough volume to cause the lesion to begin to blanch.

Second Line
- Pimecrolimus cream: 1% BID (3)[C]
- Tacrolimus ointment: 0.1% BID (3)[C]
- Chloroquine: 250 mg/day (3)[C]
- Hydroxychloroquine: 9 mg/kg/day for 2 months, 6 mg/kg/day for month 3, 2 mg/kg/day for month 4 (3)[C]
- Doxycycline: 100 mg/day for 10 weeks (3)[C]
- Isotretinoin: 0.50 to 0.75 mg/kg/day (3)[C]
- Rifampin 600 mg, ofloxacin 400 mg, with minocycline 100 mg once daily (3)[C]
- Dapsone: 100 mg/day (3)[C]
- Cyclosporine: 3 to 4 mg/kg/day (3)[C]
- Methotrexate: 15 mg IM weekly (3)[C]
- Niacinamide: 500 mg TID (3)[C]
- Fumaric acid esters: Variable dosing schemes (3)[C]
- Interferon gamma 1b: intralesional injection, $2.5 \times 10^5$ IU/lesion for 7 consecutive days followed by 3 times per week for 2 weeks (3)[C]
- TNF-α inhibitors, such as infliximab 5 mg/kg IV weeks 0, 2, and 6, then variable or adalimumab 80 mg SC at week 0, and then 40 SC at week 1 and every other week, or etanercept 50 mg twice weekly (3)[C]

ADDITIONAL THERAPIES
- Cryotherapy (one 10- to 60-second freeze thaw cycle) (3)[B]
- Fractional thermolysis (e.g., YAG fractionated laser) (3)[C]
- 585- to 595-nm pulsed dye laser (3)[C]
- Narrowband ultraviolet B (NBUVB) (6)[C]
- Psoralen ultraviolet A (PUVA) (6)[C]
- Surgical excision (for subcutaneous GA) (2)[C]
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Routine follow-up is not required unless treatment is initiated. In such situations, follow-up is recommended to monitor for possible adverse effects of treatment. Referral to a dermatologist is prudent for patients who have generalized GA, cosmetic concerns, and for patients whose lesions persist despite conservative therapy.

PATIENT EDUCATION
Patients should be educated that GA is a benign, self-limited condition that may persist for months to years, spontaneously resolve, and spontaneously recur. Additionally, patients may benefit from knowing that GA is not thought to be of an infectious etiology and is not transmissible to others.

PROGNOSIS
>50% of cases resolve spontaneously within 2 months to 2 years after onset, although recurrence, typically at the original site, is common (>40%). Patients <39 years tend to have a shorter duration of illness.

COMPLICATIONS
Complications of treatment are much more likely than complications from GA.

REFERENCES

ADDITIONAL READING

CODES

ICD10
L92.0 Granuloma annulare

CLINICAL PEARLS

- GA is benign, self-limited condition. Consider risk-to-benefit ratio when partnering with patients to determine treatment.
- When initiating therapy for localized GA, start with high-dose topical corticosteroids or intralesional corticosteroids followed by cryotherapy or other listed topical therapies. For widespread disease, consider initiating treatment with antimalarials or phototherapy (2)[C], (3)[C].
- Consider GA in the differential diagnosis of lesions that appear to be tinea, especially when these lesions lack scale and are KOH negative.
- Consider fasting lipid panel, fasting blood glucose or HbA1C, thyroid-stimulating hormone, free T4, thyroid antibodies, hepatitis B and C panel, HIV screening test, and age-appropriate cancer screening, especially in those with generalized or atypical presentations of GA (3)[C].
GRANULOMA, PYOGENIC
Cameron S. Gilbert, MD

BASICS

DESCRIPTION
- Pyogenic granulomas (PG), also called lobular capillary hemangiomas, are benign vascular proliferations that can appear on the skin and mucus membranes. Most common sites are head and neck, the lips and oral cavity, the trunk, and the extremities (1,2).
- They are friable and tend to bleed profusely due to the vascular nature of the lesion.
- Smooth, red to purple, sessile or pedunculated, grow rapidly over several weeks
- Rarely regress completely without intervention (2)

EPIDEMIOLOGY
- The peak incidence of PG occurs in children and young adults (2).
- Commonly seen in early pregnancy

ETIOLOGY AND PATHOPHYSIOLOGY
- Definitive cause unknown
- Thought to be associated with capillary proliferation resulting from aberrant healing response to minor trauma
- Associated with peripheral nerve injury, inflammatory systemic diseases, and drugs (retinoids, systemic steroids, protease inhibitors, epidermal growth factor receptor inhibitors)
- May be related to hormonal changes in pregnancy
- Not considered a hemangioma or neoplasm; no true granulomatous histology present

RISK FACTORS
- Pregnancy
- Trauma
- Intraoral trauma or surgery
- Inflammatory systemic diseases

GENERAL PREVENTION
Good oral hygiene may be helpful.

DIAGNOSIS

HISTORY
- Solitary lesion that develops rapidly from days to weeks after minor trauma
- Tends to bleed easily
- Grows early in pregnancy and partially regresses postpartum

PHYSICAL EXAM
- Most commonly located at the head, neck, and upper extremities, especially in children
- Among oral lesions, gingiva is the most common location.
- Usually a bright red, friable papule; can also be purple, yellow, or brown
- Moist and sometimes scaly-appearing surface
- Usually <1 cm but ranges from a few millimeters to 2 to 3 cm in diameter
- Giant lesions may occur on areas such as the foot (rare).
- Soft; pedunculated or sessile
- Solitary red papule, grows rapidly, forming a stalk, may bleed, and ulcerate
- On diascopy, red structureless areas surrounded by a white collarette intersected by white lines
- Erythematous, soft compressible papule with serosanguineous crusting and sharp demarcation

**DIFFERENTIAL DIAGNOSIS**
- Benign lesions
  - Cherry/infantile hemangioma (3)
  - Fibrous papule (1,3)
  - Bacillary angiomatosis, from by Bartonella (1)
- Malignant lesions
  - Basal cell carcinoma (1)
  - Squamous cell carcinoma (1)
  - Amelanotic melanoma (1)
  - Kaposi sarcoma (1)
  - Cutaneous metastases (1)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
No labs are necessary for the diagnosis.

**Diagnostic Procedures/Other**
- Excisional/shave biopsy
- Send for pathology.

**Test Interpretation**
Microscopic examination reveals
- Small, endothelial-lined vascular spaces
- Loose/dense connective tissue stroma
- Acute and chronic inflammatory cells
- No true granuloma formation
- Abundant mitotic activity
- Resembles granulation tissue in an edematous matrix, showing immature capillaries with interspersed tissue

**TREATMENT**
- Full thickness surgical excision is best to yield material for histopathologic analysis and avoid recurrence (4)[A]. Excision must be adequate to avoid recurrence. Even a small fragment of tissue left behind may lead to recurrence.
- CO₂ laser ablation results in less pain and allows for superficial dermal ablation (4)[A].
- Shave biopsy can be used for pedunculated lesions; can combine with cautery (5)[B]
- Punch biopsy acceptable for small lesions
- Electrosurgery: electrodesiccation and curettage (5)[B]
SURGERY/OTHER PROCEDURES
- Cryotherapy with liquid nitrogen (recur 2%) (5)[B]
- Pulsed dye laser or CO₂ laser (5)[B]
- Topical imiquimod (5)[B]
- Silver nitrate (5)[A]
- Topical 1.5% phenol solution may be used for periungual lesion (5)[B].
- Recurrence rate of up to 15% depending on treatment modality used

ONGOING CARE

PATIENT EDUCATION
Patient should avoid trauma to area following excision.

PROGNOSIS
- Some lesions spontaneously resolve on their own (usually within 6 months).
- With treatment, recurrence rates are between 4% and 5% (2).

COMPLICATIONS
Recurrence: After removal or destruction of solitary lesion, multiple satellite lesions can form around original treatment site.

REFERENCES

ADDITIONAL READING

CODES

ICD10

- L98.0 Pyogenic granuloma
- K06.8 Oth disrd of gingiva and edentulous alveolar ridge
- K13.4 Granuloma and granuloma-like lesions of oral mucosa

CLINICAL PEARLS

- Benign, vascular tumor, usually rapidly growing, that involves exposed areas, such as distal extremities and face, as well as in the oral cavity
- Excision must be adequate to avoid recurrence.
- Excisional biopsy recommended to ensure proper diagnosis and rule out malignancy
- Excision with primary closure is superior to shave excision with cautery in terms of recurrence risk, but both are effective.
GRAVES DISEASE
Christina A. Majd, MD • Andrew Dinh, DO • Fozia Akhtar Ali, MD

BASICS

DESCRIPTION
Autoimmune disease in which thyroid-stimulating antibodies cause increased thyroid function; most common cause of hyperthyroidism. Classic findings are goiter, ophthalmopathy (orbitopathy), and occasionally dermopathy (pretibial or localized myxedema).

EPIDEMIOLOGY

Incidence
- Annual incidence of 20 to 50 cases per 100,000 persons (1)
- Peaks between 30 and 50 years of age, but people can be affected at any age
- Occurs in 0.2% of pregnancies, of which 95% is due to Graves disease

Prevalence
- Overall prevalence of hyperthyroidism in United States: ~2% for women and 0.2% for men
- More common in white and Hispanic populations in comparison to the black population
- Graves disease accounts for 60–80% of all cases of hyperthyroidism
- Synonym(s): Basedow disease

ETIOLOGY AND PATHOPHYSIOLOGY

- Excessive production of thyroid-stimulating hormone (TSH) receptor antibodies from B cells primarily within the thyroid, likely due to genetic clonal lack of suppressor T cells
- Binding of these antibodies to TSH receptors in the thyroid activates the receptor, stimulating thyroid hormone synthesis and secretion as well as thyroid growth (leading to goiter).
- Binding to similar antigen in retro-orbital connective tissue causes ocular symptoms.

Genetics
Higher risk with personal or family history of any autoimmune disease, especially Hashimoto thyroiditis

RISK FACTORS
- Female gender (5 to 10 times more than men)
- Postpartum period
- Family history (15% of patients with Graves disease have an affected relative)
- Medications: iodine, amiodarone, lithium, highly active antiretroviral (HAART); rarely, immune-modulating medications (e.g., interferon therapy)
- Smoking (higher risk of developing ophthalmopathy)

GENERAL PREVENTION
Screening TSH in asymptomatic patients is not recommended.

COMMONLY ASSOCIATED CONDITIONS
- Mitral valve prolapse
- Type 1 diabetes mellitus
Addison disease, hypokalemic periodic paralysis
Vitiligo, alopecia areata
Other autoimmune disorders (myasthenia gravis, celiac disease)

**DIAGNOSIS**

Hyperthyroid patients appear hypermetabolic with increased adrenergic tone.

**HISTORY**

- Tachycardia, palpitations
- Tremor, restlessness
- Hyperactivity, anxiety, emotional lability, insomnia
- Sweating, heat intolerance
- Pruritus, skin changes
- Weight loss with increased appetite
- Fatigue, dyspnea (due to muscle weakness)
- Oligo-/amenorrhea (women), loss of libido, erectile dysfunction (men), gynecomastia
- Loose, frequent stools
- Blurred vision or diplopia, lacrimation, photophobia, gritty sensation in eyes (ocular dryness), retro-orbital discomfort, painful eye movement, loss of color vision or visual acuity
- Worsening of chronic medical conditions (anxiety, bipolar disorder, glucose intolerance, heart failure, or angina)

**Geriatric Considerations**

Elderly patients may not display classic symptoms; may present with atrial fibrillation, weight loss, or shortness of breath

**PHYSICAL EXAM**

- Ophthalmologic (present in 50% of cases): Grittiness/discomfort in the eyes, retrobulbar pressure/pain, lid lag/retraction, proptosis, ophthalmoplegia, papilledema, and loss of color vision may signify optic neuropathy.
- Thyroid: enlarged (goiter), nontender, and without nodules; possible bruit (increased blood flow)
- Integumentary: fine hair, warm skin, onycholysis, palmar erythema, possible pretibial myxedema (orange peel appearance), possible hyperpigmented plaques (dermopathy)
- Cardiac: resting tachycardia, hyperdynamic circulation, possible atrial fibrillation
- Extremities: fine tremor, hyperreflexia, proximal myopathy; rarely, soft tissue edema of extremities and clubbing of digits (acropachy)

**DIFFERENTIAL DIAGNOSIS**

- Toxic multinodular goiter (multiple hormone-producing nodules)
- Toxic adenoma (single hormone-producing nodule)
- Thyroiditis (hormone leakage)
  - Subacute, usually postviral (Thyroid will be tender.)
  - Lymphocytic, including postpartum
  - Hashimoto thyroiditis (Antithyroidperoxidase [TPO] antibodies may stimulate TSH receptors.)
Iatrogenic (treatment induced)
- Iodine induced (dietary, radiographic contrast, or medications)
- Amiodarone
- Thyroid hormone overreplacement (accidental or intentional)

Tumor
- Pituitary adenoma–producing TSH
- Human chorionic gonadotropin (hCG)-producing tumors (stimulate TSH receptors)
- Extraglandular thyroid hormone production (e.g., struma ovarii or metastatic thyroid cancer)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- TSH is initial test: suppressed (low or undetectable)
- TSH <0.1 mU/L has >98% sensitivity and >92% specificity in confirming suspected thyroid disease.
- Elevated free $T_4$ with low TSH confirms hyperthyroidism.

**Follow-Up Tests & Special Considerations**
Thyroid peroxidase antibodies (present in 70–80% of patients with Graves disease) and TSH receptor antibodies (thyroid binding inhibitory immunoglobulin) may be useful in differentiating between Graves disease and toxic multinodular goiter.

**Pregnancy Considerations**
- Increase in serum $T_4$-binding globulin concentration and initial stimulation of TSH by hCG results in a total $T_4$ and $T_3$ rise during first half of pregnancy. The TSH level is decreased throughout pregnancy and should be compared to the trimester-specific ranges for pregnancy. Measurement of thyrotropin receptor autoantibody (TRAb) is positive in 95% of patients with Graves and should be used if diagnosis is unclear in pregnancy (2)[A].
- Ultrasonography is the primary modality of imaging during pregnancy.

**Diagnostic Procedures/Other**
- After confirming suppressed TSH and high $T_4$, perform radioactive iodine uptake (RAIU) and scan. Patients with Graves disease will have diffuse, elevated RAIU (vs. localized/nodular elevated uptake in adenoma and multinodular goiter and decreased uptake in thyroiditis or exogenous thyroid hormone).
- Thyroid ultrasound is not always required but may be used to distinguish nodular forms of Graves disease from nodular nonautoimmune causes of hyperthyroidism.

**TREATMENT**

**GENERAL MEASURES**
Goal is to correct hypermetabolic state with the fewest side effects and lowest incidence of posttreatment hypothyroidism.

**MEDICATION**
First Line
• β-Blockers provide prompt control of adrenergic symptoms; start while workup is in progress (3)[A]. Long-acting propranolol is used most commonly and titrated to symptom control (40 to 160 mg/day).

• Antithyroid drugs: methimazole (MMI) and propylthiouracil (PTU)
  – Compete with the thyroid for iodine, thereby decreasing the synthesis of thyroid hormone; propylthiouracil blocks peripheral conversion of T₄ to T₃.
  – Treatment of choice for children and for adults who refuse RAI
  – May use as pretreatment for older or cardiac patients before RAI or surgery
  – Methimazole is now almost exclusively used except during the 1st trimester of pregnancy. It has longer duration of action, allowing for once daily dosing, more rapid efficacy, and lower incidence of side effects (3)[A].
  – No improvement in remission rates were noted with higher dose methimazole; lowest effective dose should be used (2)[B].
  – Minor side effects (<5% incidence): controlled by switching from one agent to another: skin rash (3–5%), fever, arthralgias, GI side effects
  – Major side effects necessitating change in treatment: polyarthritis (1–2%), idiopathic granulocytopenia (0.5%), and cholestasis/jaundice (rare)
  – Evidence suggests that the optimal duration of antithyroid drugs is 12 to 18 months; no increased benefit to treatment beyond 18 months (4)[A].
  – Relapse rates up to 50% in patients who respond initially; higher rates if smoker, large goiter, or positive thyroid-stimulating antibodies at end of treatment

• RAI
  – Concentrates in the thyroid gland and destroys thyroid tissue
  – Radioiodine plus prednisone therapy might have the least probability of leading to an exacerbation or new appearance of ophthalmopathy, and radioiodine therapy might have the least probability of causing a recurrence (4)[A].
  – Treatment of choice for definitive therapy of hyperthyroidism, in the absence of moderate or severe orbitopathy (2)[A]
  – High cure rate with single treatment, especially with high-dose regimen
  – Risks: side effects (neck soreness, flushing, decreased taste); worsening ophthalmopathy (15% incidence, higher in smokers); posttreatment hypothyroidism (80% incidence, not dosage dependent); radiation thyroiditis (1% incidence); need to adhere to safety precautions until radiation is eliminated from the body
  – Pretreatment with antithyroid medication should be considered in patients with severe disease and the elderly, to reduce risk of posttreatment transient hyperthyroidism and posttreatment radiation thyroiditis as well as quicker return to normal thyroid function.
  – May be repeated in as soon as 3 months if minimal response or after 6 months if not euthyroid (3)[A]

Pregnancy Considerations
RAI is contraindicated in pregnancy and during breastfeeding

• Antithyroid drugs: methimazole (MMI) and propylthiouracil (PTU)
  – Propylthiouracil is preferred in 1st trimester of pregnancy due to teratogenic effects of methimazole. Switch to methimazole in 2nd and 3rd trimesters due to risk of PTU-induced hepatotoxicity (5)[A].

ISSUES FOR REFERRAL
- Endocrinologist for RAI therapy; if patient is pregnant or breastfeeding
- Graves ophthalmopathy
- Surgery if failed drug therapy or refusing RAI; obstruction or cosmesis

**ADDITIONAL THERAPIES**
- Symptom control may be achieved with iodides, which block conversion of T4 to T3 and inhibit TSH release. Use for pregnant patients who do not tolerate antithyroid medication or in conjunction with antithyroid medications; should not be used long term (may cause paradoxical increase in TSH release) or in combination with RAI
- For corneal protection: tinted glasses when outdoors, artificial tears, patching/taping the lids at night
- For orbitopathy: Mild cases can be treated with lubricants, nocturnal ointments, botulinum toxin injection for upper lid retraction, and smoking cessation. Moderate to severe cases should be treated with pulse-dose IV glucocorticoid if no contraindications. Alternative is PO steroid (prednisone 60 to 80 mg/day for 2 to 4 weeks and then taper off).
- For dermopathy, use medium- to high-potency topical corticosteroids.

**SURGERY/OTHER PROCEDURES**
With regard to ophthalmopathy progression, postoperative bleeding, permanent hypoparathyroidism, temporary and permanent recurrent laryngeal nerve palsy—total thyroidectomy (TT) is consistent with subtotal thyroidectomy (ST) in patients with Graves disease. However, TT is associated with a reduced incidence of recurrent hyperthyroidism and results in an increase in temporary hypoparathyroidism (6)[A].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Indications for hospital admission:
- Severe thyrotoxicosis with hemodynamic compromise (thyroid storm). ICU management is indicated.
- Severe ophthalmopathy with visual compromise

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Monitoring is for the resolution of hyperthyroidism and for the development of hypothyroidism.
- Check TSH and T4 levels every 1 to 2 months for the first 6 months after treatment, then every 3 months for a year, and then every 6 to 12 months thereafter. For patients on treatment with propylthiouracil and methimazole, check complete blood count yearly. Also, check anti-TSH receptor antibodies at 12 months of treatment to determine possibility of discontinuing medication.

**Pregnancy Considerations**
Postpartum exacerbation of hyperthyroidism is common for women not currently under treatment, so TSH and symptoms should be monitored.
PATIENT EDUCATION
Adherence to both follow-up surveillance and medication regimens is the most important way to achieve a good outcome.

PROGNOSIS
- Generally good with treatment
- May have irreversible ocular, cardiac, and psychiatric consequences
- Increased morbidity and mortality due to osteoporosis, atherosclerotic disease, insulin resistance and obesity, and endothelial cell dysfunction (thromboembolic risk)

COMPLICATIONS
Hypothyroidism is the most common consequence of treatment. The percentage of patients with Graves disease who become hypothyroid within the 1st year after treatment varies with treatment modality.

CODES

ICD10
- E05.00 Thyrotoxicosis w diffuse goiter w/o thyrotoxic crisis
- E05.01 Thyrotoxicosis w diffuse goiter w thyrotoxic crisis or storm
- E05.20 Thyrotoxicosis w toxic multinod goiter w/o thyrotoxic crisis
CLINICAL PEARLS

- Graves disease accounts for 60–80% of all cases of hyperthyroidism.
- Potential morbidities of hyperthyroidism include ophthalmopathy, atrial fibrillation, congestive heart failure (CHF), stroke, seizure, and osteopenia/osteoporosis.
GUILLAIN-BARRÉ SYNDROME
Grant M. Reed, DO ● Simon B. Griesbach, MD

BASICS
DESCRIPTION
- A group of acquired autoimmune disorders causing acute peripheral neuropathy and ascending paralysis that progressively worsens for up to 4 weeks followed by a slow spontaneous recovery of function
- Subtypes classified by pattern of neural injury:
  - Acute inflammatory demyelinating polyradiculoneuropathy (AIDP): progressive limb weakness with areflexia (~95% of GBS cases in Europe and North America)
  - Axonal subtypes:
    o Acute motor axonal neuropathy (AMAN): pure motor neuropathy strongly associated with Campylobacter jejuni and a higher rate of respiratory failure (~5% of cases in Europe and North America but 30–47% of cases in China, Japan, and Central and South America)
    o Acute motor-sensory axonal neuropathy (AMSAN): combined motor–sensory neuropathy; poor prognosis with prolonged course
  - Regional subtypes:
    o Miller Fisher syndrome (MFS): triad with ophthalmoplegia, ataxia, and areflexia; antibodies to GQ1b present in 90% of patients with MFS
    o Bickerstaff encephalitis: possible variant of MFS with encephalopathy, ophthalmoplegia, ataxia, and hyperreflexia
    o Pharyngeal-cervical-brachial GBS: Parasympathetic and cholinergic dysfunction leads to neck, arm, and oropharyngeal weakness along with upper extremity areflexia.
  - Sensory subtypes:
    o Acute pandysautonomia: orthostatic hypotension, gastroparesis, ileus, constipation/diarrhea, sudomotor/pupillary abnormalities, and neuropathic pain
    o Acute sensory ataxic neuropathy (ASAN): controversial variant with sensory loss and ataxia
- Polyneuritis cranialis: bilateral cranial nerve involvement and severe peripheral sensory loss associated with cytomegalovirus (CMV) infections
- Synonym(s): GBS, AIDP; Landry-Guillain-Barré-Strohl syndrome, acute inflammatory idiopathic polyneuritis; acute autoimmune neuropathy; Landry ascending paralysis

ALERT
Rapidly progressing paralysis and respiratory failure occur in 20–30% of patients. Some require mechanical ventilation within 48 hours.

ALERT
Areflexia is a red flag for GBS in patients with rapidly progressive limb weakness.

ALERT
A history of weakness preceded by respiratory or GI infection suggests GBS.
EPIDEMIOLOGY

Incidence
- Most common acute paralytic disease in Western countries
- 0.6 to 2.0/100,000 worldwide
- U.S. incidence: 0.9 to 1.8/100,000
- Increases with age: 0.8/100,000 in children <18 years of age; 3/100,000 in adults >60 years
- 1.5 times higher incidence in males

ETIOLOGY AND PATHOPHYSIOLOGY
- Post-infectious autoimmune process targets Schwann cell surface membrane, myelin, and/or gangliosides causing peripheral nerve destruction and demyelination.
- Pathogenesis thought to involve molecular mimicry (i.e., an immune response to antigenic targets that are coincidentally shared by infectious organisms and host peripheral nerve tissue). Antibodies cross-react with GM1 myelin ganglioside with resultant damage to peripheral nervous system.

Genetics
Host factors appear to play a role in GBS, but no clear genetic risk has been identified.

RISK FACTORS
Influenza vaccinations
- Inactivated seasonal flu vaccines associated with an increase in GBS risk equivalent to one case/million vaccines above background incidence (far less than the 17 cases of GBS per million people infected with influenza virus).
- Incidence of GBS associated with flu vaccine decreasing over time with no increase detected in 2017–18 season.
- Of historical note: Increased incidence during 1976 U.S. National H1N1 Immunization Program had vaccine-attributable risk of 8.8 per million recipients compared to 1.6 per million recipients in the 2009 H1N1 vaccination campaign.

COMMONLY ASSOCIATED CONDITIONS
Infection of the respiratory (22–53%) or GI (6–26%) tract in preceding 6 weeks
- Campylobacter jejuni: most common precipitant of GBS (21–40% of cases):
  - Associated with axonal degeneration, slower recovery, more severe residual disability
- Cytomegalovirus (CMV): Primary CMV infection precedes 10–22% of cases.
- Rarely associated with Mycoplasma pneumoniae, influenza infection, Epstein-Barr virus, varicella-zoster virus, HIV infection, Zika virus, and some arboviral infections

DIAGNOSIS

HISTORY
- AIDP presents with onset of progressive limb weakness that reaches its worst within 4 weeks (73% reach a functional nadir in 1 week; 98% by 1 month).
- Preceding respiratory or gastrointestinal infection
- Earliest symptoms include pain, numbness, paresthesias, or proximal muscle weakness that can spread to involve cranial nerves and muscles of respiration.
- Cranial nerve symptoms: facial nerve palsy; diplopia; dysarthria; dysphagia; ophthalmoplegia
Neuropathic pain, sometimes severe, occurs in 30–50%, most commonly in the back and lower extremities.
Purely sensory symptoms exclude GBS.

PHYSICAL EXAM
Diagnostic criteria for typical GBS:
- Required for diagnosis:
  - Progressive weakness reaching nadir between 12 hours and 28 days
  - Affects >1 limb
  - Areflexia/hyporeflexia
- Strongly supportive:
  - Paresthesias with only mild changes in objective sensory function (e.g., pinprick, light touch)
  - Relative symmetry
  - Cranial nerve involvement, especially bilateral/symmetric weakness of facial muscles
  - Recovery beginning within 4 weeks after progression ceases
  - Autonomic dysfunction (tachycardia, bradycardia, facial flushing, hypertension, hypotension, anhidrosis, diaphoresis), urinary retention, diarrhea, constipation
  - Absence of fever at onset

DIFFERENTIAL DIAGNOSIS
Differential diagnosis of acute flaccid paralysis:
- Brain: basilar artery stroke, brainstem encephalitis
- Spinal cord: transverse myelitis, spinal cord compression
- Motor neuron: poliomyelitis, acute flaccid myelitis
- Peripheral neuropathy other than GBS: vasculitis, critical illness polyneuropathy, infectious disease (e.g., diphtheria, Lyme disease, HIV), chronic inflammatory demyelinating polyradiculoneuropathy (CIDP), acute intermittent porphyria
- Neuromuscular junction: myasthenia gravis, Eaton-Lambert syndrome, botulism, toxins (e.g., heavy metals, inhalant abuse, organophosphates)
- Muscle: electrolyte disturbance (hypokalemia, hypophosphatemia), inflammatory myopathy, critical illness myopathy, acute rhabdomyolysis, trichonosis, periodic paralysis
- Psychological causes of weakness

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Studies to establish the diagnosis:
  - Lumbar puncture (LP): Increased CSF protein (most patients with GBS will have CSF protein >400mg/L) without pleocytosis is present in ~80% of cases (Note: CSF protein is often normal within the first 48 hours of symptom onset).
  - Nerve conduction study (NCS): Most useful confirmatory test; conduction velocities abnormal in 85% of patients with demyelination, even early in the disease. If nondiagnostic, repeat after 1 to 2 weeks.
- Imaging generally not required. MRI demonstrates spinal nerve root and/or cauda equina enhancement.
- Studies to find underlying cause:
  - Stool culture and serology for C. jejuni
Acute and convalescent serology for CMV, EBV, HIV, and M. pneumoniae
- Anti-GQ1b antibodies in MFS variant and anti-GM1 antibodies in AMAN
- Peripheral neuropathy: TFT; rheumatoid factor, B12/folate; Hemoglobin A1C; ESR; RPR; heavy metal assay

Follow-Up Tests & Special Considerations
- Analyze CSF prior to treatment with intravenous immunoglobulin (IVIG), which can cause aseptic meningitis.
- A repeat NCS 3 to 8 weeks after onset can classify the subtype of GBS.

Diagnostic Procedures/Other
- Sural nerve biopsy not indicated except to rule out vasculitis or amyloidosis.

TREATMENT

GENERAL MEASURES
- Consider admission to ensure that disease does not progress (respiratory function, autonomic stability, paralysis).
- Supportive care is essential, paying close attention to complications of immobility, neurogenic bladder/bowel and pain management.
- Pain treatment: NSAIDs helpful but often insufficient. Gabapentin and carbamazepine decrease opioid requirements in patients with GBS. One is not superior to others (1)[A].
- DVT prophylaxis recommended in nonambulatory patients (2)[C].
- Neostigmine or erythromycin may be effective for ileus, if present (2)[C].

MEDICATION

First Line
- IVIG 0.4 g/kg/day for 5 days or (less commonly) 1g/kg/day for 2 days:
  - In severe disease, IVIG started within 2 weeks of onset hastens recovery as much as plasma exchange (PE) (3)[A].
  - In children, IVIG hastens recovery compared with supportive care alone (3)[A].
  - Combined treatment with IVIG and PE confers no clinically significant benefit (3)[A].
- PE:
  - Compared with supportive treatment alone, those treated with PE are quicker to recover walking (NNT 7), have less requirement and shorter duration for mechanical ventilation (NNT 8), recover full muscle strength more quickly (NNT 8), and have fewer severe sequelae at 1 year (NNT 17) (4)[A].
  - Higher risks of relapse found with PE versus supportive care with no difference in severe infection or mortality (4)[A].
  - In mild GBS, two sessions of PE are superior to none. In moderate GBS, four sessions are superior to two. In severe GBS, six sessions are not significantly better than four (4)[A].
  - PE is most beneficial if started within 7 days of disease onset. PE still helpful up to 30 days (4)[A].
  - Value of PE in children <12 is unknown.

Second Line
• Corticosteroids: not beneficial as monotherapy or as combined treatment. Low-quality evidence suggests steroids delay recovery (5)[A].
• CSF filtration is no different than PE (6)[B].
• Interferon β and brain-derived neurotrophic factor no different than placebo (6)[B].

ADDITIONAL THERAPIES
• Physical and occupational therapy improves fatigue and functional abilities (2)[C].
• Speech and language therapy improves swallowing function, if affected (2)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE
Tripterygium polyglycoside hastened recovery significantly more than corticosteroids (NNT 4) in one small trial (6)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Admit patients with suspected GBS.
• Closely monitor respiratory status with serial measurement of vital capacity (VC) and static inspiratory and expiratory pressures (PI\textsubscript{max} and PE\textsubscript{max}).
• Predictors of respiratory failure:
  – Rapid progression: ≥3 days between onset of weakness and hospital admission
  – Facial and/or bulbar weakness
  – VC decrease >30%
  – Medical Research Council (MRC) sum score indicating muscle weakness: 0 to 5/5 muscle strength grading for bilateral upper arm abductors, elbow flexors, wrist extensors, hip flexors, knee extensors, and foot dorsal flexors totaling 60 points
• Indications for intubation:
  – VC <20 mL/kg
  – PI\textsubscript{max} <30 cm H\textsubscript{2}O
  – PE\textsubscript{max} <40 cm H\textsubscript{2}O
• Prevent complications of immobilization with DVT prophylaxis and frequent turning.
• Respiratory care, aspiration precautions, pulmonary toilet
• Monitor bowel and bladder function for ileus and urinary retention.
• Begin immediate physical therapy to preserve passive range of motion.
• Mildly affected patients who can walk unaided and are stable for >2 weeks are unlikely to experience disease progression and may be managed as outpatients. Monitor bowel and bladder function for ileus and urinary retention.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
• Patients require close monitoring of respiratory, cardiac, and hemodynamic function, typically in the ICU setting.
• Pulmonary function testing (VC, respiratory frequency) q2–6h in the progressive phase and q6–12h in the plateau phase
• Monitor bulbar weakness and ability to handle airway secretions.
• Telemetry in patients with severe disease
PATIENT EDUCATION
Emphasize expectation for significant recovery and explain phases of illness.

PROGNOSIS
- If untreated, three phases of illness:
  - Initial progressive phase up to 4 weeks with highest risk of death and complication
  - Variable plateau phase
  - Recovery phase (weeks to months): return of proximal then distal strength
- Most recovery occurs within the first year.
- 80% recover within 6 to 12 months with maximum 18 months past onset.
- 20–39% with residual disability after 1 year:
  - Bilateral footdrop, intrinsic hand muscle wasting, sensory ataxia, dysesthesia, fatigue, musculoskeletal pain
  - Half of these with severe disability
- Factors associated with poor functional outcome:
  - Age >60 years, rapid progression, severe disease, severe disability on either admission or discharge, preceding diarrhea, male sex, positive C. jejuni or CMV serology, axonal degeneration, need for mechanical ventilation

COMPLICATIONS
- 3–7% mortality in Europe and North America. Older patients, those with severe disease have highest risk.
- 20–30% require mechanical ventilation.
- 70% develop autonomic dysfunction with hemodynamic instability, urinary retention, ileus, and anhidrosis.
- 10% have relapse.
- ~2% develop relapsing CIDP.

REFERENCES

ADDITIONAL READING

CODES

ICD10
G61.0 Guillain-Barré syndrome

CLINICAL PEARLS

- Suspect GBS in cases of ascending flaccid paralysis with areflexia and an antecedent history of viral respiratory illness or gastroenteritis.
- When GBS is suspected, evaluate VC and inspiratory force for signs of respiratory compromise.
- Uncomplicated GBS has a slow spontaneous recovery. Treatment with IVIG or PE speeds rate of recovery and reduces disability.
- The most useful diagnostic tests for GBS are nerve conduction studies and lumbar puncture.
- GBS risk following native influenza virus infection is 40 to 70 times greater than after seasonal influenza vaccination.
GYNECOMASTIA
Franklyn C. Babb, MD, FAAFP

BASICS

DESCRIPTION
- Benign glandular proliferation of male breast tissue
- Increase in estrogen activity relative to androgen leads to the development of gynecomastia
- Gynecomastia can be transient and may represent the normal physiologic changes that occur in utero or in adolescence. However, gynecomastia presenting or persisting in adulthood is typically pathologic in nature.
- Pseudogynecomastia, which is lipomastia (subareolar fat)

EPIDEMIOLOGY
- 60–90% of infants have transient gynecomastia (1).
- 50–60% of pubertal males have mild transient gynecomastia (onset at 10 to 12 years of age and resolution by age 18 years in most individuals) (1).
- Up to 70% of men between 50 and 69 years of age report gynecomastia (1).

Incidence
A study out of Bulgaria in 2007 put the incidence of pubertal gynecomastia at 3.9% in Caucasian boys ages 10–19 (2).

ETIOLOGY AND PATHOPHYSIOLOGY
Increase in estrogen activity relative to androgen activity leads to the development of gynecomastia. Estrogen stimulates ductal cell hyperplasia, facilitates ductal branching and lengthening, increases vascularity, and results in the proliferation of periductal fibroblasts. These changes occur within 12 months and are followed by fibrosis in the later stages of gynecomastia. Multiple factors can alter the estrogen-to-androgen ratio and precipitate gynecomastia:
- Decrease in androgen production
- Increase in estrogen production
- Increase in peripheral conversion to estrogen
- Inhibition of the androgen receptor
- Increase in the level of sex hormone–binding globulin (SHBG) or the affinity of androgens to SHBG (decreases free or bioavailable testosterone)
- Displacement of estrogen relative to testosterone from SHBG due to medications

RISK FACTORS
Gynecomastia can be physiologic or pathologic in nature.
- Physiologic gynecomastia presents in infants and adolescent boys and resolves spontaneously.
  - Neonatal gynecomastia: The placenta converts dehydroepiandrosterone (DHEA) and dehydroepiandrosterone sulfate (DHEA-S) to estrone and estradiol resulting in transient gynecomastia.
  - Adolescent gynecomastia: Transient increases in estradiol levels at the onset of puberty lead to gynecomastia.
- Pathologic gynecomastia refers to persistent or adult-onset gynecomastia. 25% of cases are
idiopathic in nature most likely secondary to age-associated decline in free testosterone and adipose tissue–mediated aromatase activity.

- Multiple medications have been implicated (1).

**ALERT**

- Illicit drugs: marijuana, heroin, methadone, alcohol, amphetamines, and over-the-counter bodybuilding supplements
- Hormones: androgens, anabolic steroids, estrogens, estrogen agonist, and human chorionic gonadotropin (hCG)
- Antiandrogens or inhibitors of androgen synthesis: bicalutamide, flutamide, nilutamide, cyproterone, and GnRH agonists (leuprolide and goserelin)
- Anti-infectives: metronidazole, ketoconazole, minocycline, isoniazid
- Anti-ulcer medications: cimetidine, ranitidine, metoclopramide, and proton pump inhibitors
- Cytotoxic agents: methotrexate, alkylating agents, and vinca alkaloids
- Cardiovascular drugs: digoxin, spironolactone, calcium channel blockers, ACE inhibitors, amiodarone, methyldopa, reserpine, minoxidil, and recently statins can be added to this list (3)
- Psychoactive drugs: antidepressants, benzodiazepines, phenothiazines, antipsychotics (typical and atypical) (i.e., haloperidol and risperidone)
- Medications: HIV medications like efavirenz, phenytoin, penicillamine, sulindac, or theophylline
- Causes to rule out:
  - Primary hypogonadism: androgen insensitivity syndromes (defect in the androgen receptor), Klinefelter syndrome
  - Testicular tumor: germ cell (secretes hCG), Leydig cell (secretes estrogen), Sertoli cell (excessive aromatization to estrogens)
  - Adrenal tumors (secrete DHEA-S and estrogens)
  - Ectopic hCG tumors (hepatoblastoma, gastric tumors, renal cell carcinomas)
  - Cirrhosis
  - Secondary hypogonadism: Kallmann syndrome or prolactinemia, which can also stimulate milk production in breast tissue
  - Hyperthyroidism
  - Renal disease or dialysis
  - Malnutrition/starvation
  - Rare (true hermaphroditism [both testicular and ovarian tissue present])

**Pediatric Considerations**

Transient gynecomastia is seen in neonates or pubertal boys; typically resolves within 6 to 24 months

**Geriatric Considerations**

Age-associated decline in testosterone production and increase in SHBG production leads to low free testosterone levels in the elderly population. Furthermore, the increased ratio of fat mass to lean mass noted with aging leads to adipose tissue–mediated peripheral conversion of androgens to estrogen. Medications also play a significant role in the development of gynecomastia in this population.

**COMMONLY ASSOCIATED CONDITIONS**

- Prostate carcinoma—treatment with estrogen and antiandrogen leads to gynecomastia in 50–
75% of patients.
- Cirrhosis
- Primary hypogonadism; especially Klinefelter syndrome—congenital abnormality leads to primary hypogonadism and gynecomastia. These patients are at risk for breast cancer and need regular breast exams.
- Testicular tumors; Leydig or Sertoli cell tumors especially when associated with Peutz-Jeghers syndrome or Carney complex

**DIAGNOSIS**

**HISTORY**
- Inquire about duration of breast growth, increase in breast tissue size, and associated breast pain and discharge.
- If suspicious of hypogonadism, ask about erectile dysfunction, muscle mass, and decreased shaving frequency and libido.
- Obtain a complete medical history including headache, loss of vision, loss of appetite, weight loss, malignancy, thyroid disorders, liver disease, renal disease, and genetic abnormalities.
- Obtain a family history including Carney complex and Peutz-Jeghers syndrome.
- Review medication list extensively and inquire about the use of illicit substances.
- Question about herbal supplements, marijuana use, and over-the-counter cimetidine (Tagamet) or other H2 antagonist use.

**PHYSICAL EXAM**
- Careful breast exam to evaluate characteristics:
  - Firm, concentric glandular tissue beneath the nipple and areola palpable by pinching the thumb and forefinger together from either side of the breast toward the nipple. Diameter of this tissue for diagnostic purposes ranges from >0.5 cm to >2.0 cm, but the most recent large study recommended 1.0 cm as the diagnostic criteria (2).
  - May involve one or both breasts
  - Usually asymptomatic but may be painful or tender if it is of recent onset
  - Off center, hard, fixed mass is concerning for malignancy, although palpation of subareolar fat is more consistent with pseudogynecomastia.
  - Breast discharge should raise concern for malignancy or prolactinemia. In the latter, the discharge is typically clear or milky.
- Thyroid exam (Evaluate for diffuse enlargement and palpable nodules and check extremities for tremor and brisk reflexes.)
- Abdominal exam (Evaluate for masses and liver size.)
- Genitourinary exam (Evaluate for testicular size, hair pattern, and presence of ovary or uterus.)
- Visual field exam (Evaluate for peripheral field defect.)

**DIFFERENTIAL DIAGNOSIS**
- Pseudogynecomastia—fat deposition without glandular proliferation often seen in obesity
- Breast cancer—on exam, the lesion is typically unilateral; firm; eccentric to the nipple; and associated with skin dimpling, nipple retraction/discharge, and lymphadenopathy.
- Lipomas
- Sebaceous cyst
- Dermoid cyst
- Mastitis
- Hematoma
- Hamartoma

**DIAGNOSTIC TESTS & INTERPRETATION**

- Laboratory and radiologic investigations should be tailored to fit history and physical exam findings.
- Idiopathic gynecomastia is a diagnosis of exclusion, and therefore, laboratory tests to rule out medical conditions associated with gynecomastia is recommended.

**Initial Tests (lab, imaging)**

- Luteinizing hormone (LH)—elevated in primary hypogonadism and decreased in secondary hypogonadism
- Morning total and free testosterone—decreased testosterone level in hypogonadism
- hCG—elevated in germ cell tumors and ectopic hCG tumors
- Estradiol—elevated in Leydig cell tumors, Sertoli cell tumors, adrenal tumors, and with increased aromatase activity
- DHEA-S levels, which can be increased in adrenal tumors
- Urine for drugs of abuse (UDA)
- Other tests to consider include creatinine, liver function test, thyroid function tests, and prolactin.

**Follow-Up Tests & Special Considerations**

Consider imaging studies based on laboratory findings.

- Testicular ultrasound (testicular tumor)
- Chest x-ray (CXR) and abdominal computed tomography (CT)/magnetic resonance imaging (MRI) (extragonadal germ cell tumor, ectopic hCG tumor, and adrenal tumor)
- MRI of pituitary (pituitary tumor)

**Diagnostic Procedures/Other**

Based on physical exam findings, consider biopsy of breast mass to rule out malignancy (i.e., off center, hard, fixed, discharge).

**Test Interpretation**

- Elevated hCG: Check testicular ultrasound. If positive for a mass, likely a testicular germ cell tumor. If the ultrasound is negative, consider extragonadal germ cell tumor or hCG-secreting neoplasm and order a CXR and CT abdomen.
- Elevated LH: if in relation to low testosterone, likely primary hypogonadism. If elevated in relation to high testosterone, check thyroid-stimulating hormone (TSH) and free thyroxine (FT<sub>4</sub>). If FT<sub>4</sub> is elevated and TSH is suppressed, likely hyperthyroidism; if TSH and FT<sub>4</sub> are normal, likely androgen resistance
- Normal or decreased LH in relation to low testosterone: Check prolactin level. If prolactin is elevated, likely due to a prolactin-secreting pituitary tumor; if normal, likely due to secondary hypogonadism
- Normal or decreased LH in relation to increased estradiol: Check testicular ultrasound. If positive for a mass, likely Leydig or Sertoli cell tumor. If negative for mass, check CT abdomen to evaluate the adrenals. If mass is present, possible adrenal neoplasm versus
adenoma; if no mass is detected, then likely due to increased aromatase activity in extraglandular tissue
- hCG, LH, testosterone, and estradiol are normal: likely idiopathic or medication/drug-induced gynecomastia

**TREATMENT**

**GENERAL MEASURES**
- Gynecomastia usually regresses spontaneously within 6 months of onset. This is true even for adult males. Therefore, patients can be monitored for the first 6 months and treatment considered if gynecomastia persists.
- The histologic changes early in the disease process can be reversed with medical therapy. However, with the development of fibrotic tissue, surgery is typically required. Typically, 1 to 2 years after the onset of gynecomastia, fibrotic changes can be seen and medical intervention is less effective.
- Neonatal and pubertal gynecomastia spontaneously resolves within 6 to 24 months. Persistent pubertal gynecomastia (>24 months) occurs in 8% of pubertal boys. In adult males, 75% of gynecomastia is secondary to persistent pubertal gynecomastia, medications, and idiopathic conditions. Only 25% is related to an underlying medical condition.
- All illicit drug use and offending medications should be stopped if appropriate and patients monitored for clinical improvement.
- Underlying medical conditions need to be treated (i.e., testosterone replacement for hypogonadal men, dopamine agonist for prolactinoma, appropriate treatment for thyrotoxicosis, and tumor resection).
- Medical and surgical therapy to reduce gynecomastia should be considered in patients with significant physical or psychological discomfort.

**MEDICATION**

There are no Food and Drug Administration-approved medications for the treatment of gynecomastia, but clinical trials involving selective estrogen receptor modulators (SERMs) and aromatase inhibitors demonstrate partial regression and symptom relief (i.e., breast tenderness).
- **SERMs:** Clinical trials of both tamoxifen (10 to 20 mg/day) and raloxifene (60 mg/day) showed partial reduction in pubertal gynecomastia in 90% of study participants after 3 to 9 months, but 40% of patients in both treatment groups were not satisfied with the final results and underwent surgical removal. Tamoxifen has also been shown to reduce breast tenderness and prevent the development of gynecomastia in prostate cancer patients on androgen deprivation therapy. Therefore, SERMs (particularly tamoxifen) can be considered in men with 6 to 12 months of severe, painful gynecomastia symptoms (4)[B].
- **Aromatase inhibitors** block peripheral conversion of androgens to estrogens. In prostate cancer patients, anastrozole prevented the development of gynecomastia in patients undergoing androgen deprivation therapy.

**ISSUES FOR REFERRAL**
- Refer patients to an endocrinologist if abnormally elevated hormone levels are confirmed.
- If patients have refractory gynecomastia despite medical therapy and have prolonged gynecomastia characterized by the late fibrotic stage or symptoms concerning for breast
cancer, referral to a surgeon would be appropriate.

**ADDITIONAL THERAPIES**

In clinical trials, prophylactic radiotherapy (10 to 15 Gy in one fraction over 3 days) prevented the development of gynecomastia in prostate cancer patients on androgen deprivation therapy. Higher doses (20 Gy in five fractions) improved pain symptoms in the same population (4)[B].

**SURGERY/OTHER PROCEDURES**

Surgery to remove breast tissue is recommended if:
- Gynecomastia does not regress within 12 months either spontaneously or after medical therapy.
- Significant discomfort (i.e., pain, tenderness)
- Causes embarrassment or anxiety
- Biopsy suspicious for malignancy

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Every 3 to 6 months for 24 months; consider medical therapy (i.e., tamoxifen) if severe, painful symptoms persist after 6 to 12 months and surgery after 12 to 24 months. In individuals with asymptomatic or mild disease, routine yearly breast and physical exam is recommended.
- Patients with Klinefelter syndrome are at increased risk of breast cancer and should have routine breast exams done.

**PATIENT EDUCATION**

Patients should be encouraged to do periodic breast examination and to alert their clinical provider if a nodule is palpated in the breast or axilla, skin discoloration occurs, or nipple discharge develops.

**PROGNOSIS**
- Good in physiologic cases because they often regress spontaneously within 3 to 6 months
- Majority of patients experience regression once underlying disorder is treated or offending agents are eliminated.
- The majority of patients who undergo surgery are satisfied with the postoperative cosmetic appearance (5).

SEE ALSO
Algorithm: Gynecomastia

CODES
ICD10
N62 Hypertrophy of breast

CLINICAL PEARLS
- Gynecomastia can be transient and may represent the normal physiologic changes in neonates or adolescents. However, gynecomastia presenting or persisting in adulthood is typically pathologic in nature.
- Thorough history and physical exam should be performed on all patients and offending medications eliminated.
- Lab and radiologic studies should be conducted to rule out medical conditions associated with gynecomastia including thyrotoxicosis, prolactinemia, hypogonadism, testicular tumors, adrenal tumors, and ectopic hCG tumors. Treatment should be tailored to exam findings.
- ~25% of gynecomastia is idiopathic in nature, and treatment should focus on symptom control.
- Clinical trials of SERMs, aromatase inhibitors, and radiation therapy seem promising. Surgery is the treatment of choice for refractory gynecomastia.
Hammer Toes
Neil Feldman, DPM

BASICS
Contraction deformities of the toes

DESCRIPTION
- Hammer toes include three distinct types of deformity.
  - Hammer toe (as defined) involves a plantar flexion deformity of the proximal interphalangeal (PIP) joint with varying degrees of hyperextension of the metatarsophalangeal (MTP) and distal interphalangeal (DIP) joint; primarily in sagittal plane (1)
  - Claw toe involves a plantar flexion deformity of the PIP and DIP joint with varying degrees of hyperextension of the MTP.
  - Mallet toe involves a plantar flexion deformity of the DIP joint only.
- Each can be flexible, semirigid, or fixed.
  - Flexible: passively correctable to neutral position
  - Semirigid: partially correctable to neutral position
  - Fixed: not correctable to neutral position without intervention

EPIDEMIOLOGY
Most common deformity of lesser digits, typically affecting only one or two toes:
- 2nd toe is the most commonly involved.
- Hallux malleus is term used when the great toe (hallux) is involved.

Incidence
- Undefined
- Increases with age, duration of deformity (from flexible to rigid)

Prevalence
- Predominant sex: female > male (2)
  - Female predominance from 2.5:1 to 9:1, depending on age group
- Can range from 1% to 20% of population studied
- Blacks are more often affected than whites (2).

ETIOLOGY AND PATHOPHYSIOLOGY
- Can be congenital or acquired
- Three categories of acquired hammer toes
  - Extensor substitution (most common with pes cavus). Occurs during the swing phase of gait. The extensor digitorum longus (EDL) muscle remains overactive, substituting for dysfunctional hip and ankle extensors.
  - Flexor substitution. Least common cause and seen commonly with pes cavus. The flexor digitorum longus (FDL) muscle remains overactive with relative weakness/dysfunction to the Achilles and flexor hallucis longus (FHL), which are the main foot flexors.
  - Flexor stabilization (most common cause and occurs in pronated foot/foot with pes planus). The FDL muscle remains overactive, overutilizing the toes to assist in relative foot
Biomechanical dysfunction results in muscle/tendon imbalance between the EDL tendon at the PIP joint and the FDL tendon at the MTP joint; the imbalance at the MTP joint level leads to the altering of the stabilizing force of the intrinsic muscles inserting into the extensor sling and wing apparatus of the MTP joint. In the case of classic hammer toes, the toe(s) sublux dorsally as the MTP hyperextends. This results in plantar flexion of the PIP joint and hyperextension of the MTP joint (2).

Specific pathomechanics vary by etiology:
- Toe length discrepancy or narrow footwear toe box induces PIP joint flexion by forcing digit to accommodate shoe.
  - May also lead to MTP joint synovitis secondary to overuse, with elongation of plantar plate and MTP joint hyperextension
  - 4th and 5th toes commonly assume an adductovarus attitude, which can make the toes appear to sit on their side.
- Rheumatoid arthritis (RA) causes MTP joint destruction and resultant subluxation.
- Any condition that compromises intra-articular and periarticular tissues, such as second ray longer than first, inflammatory joint disease, neuromuscular conditions, improper-fitting shoes, and trauma (3)
  - Damage to joint capsule, collateral ligaments, or synovia leads to unstable PIP joint or MTP joint.

**Genetics**
- Significant heritability rates of 49–90% (4)
- Specific genetic markers are not identified.

**RISK FACTORS**
- Pes cavus, pes planus
- Hallux valgus
- Metatarsus adductus
- Ankle equinus
- Neuromuscular disease (rare)
- Trauma; improperly fitted shoes (narrow toe box) and/or tight hosiery
- Abnormal metatarsal and/or digit length
- Inflammatory joint disease (e.g., RA)
- Connective tissue disease
- Diabetes mellitus

**GENERAL PREVENTION**
- Proper fitting of shoes. Use of pressure-dispersive footwear helps reduce pain.
- Foot orthoses modulate biomechanical dysfunction and muscular imbalance, preventing progression (2).
- Limiting use of shoes in the growing foot. Use of zero drop shoes when necessary. Traditional shoes have an elevated heel relative to the ball of the foot (MTP joints). Therefore, at rest, the toes are positioned in dorsal subluxation at the MTP joints and forced to be contracted (termed toe spring).
- Control of predisposing factors (e.g., inflammatory joint disease) may also slow progression.

**COMMONLY ASSOCIATED CONDITIONS**
- Hallux valgus
- Cavus foot (pes cavus)
- Flat foot (pes planus)
- Metatarsus adductus
- Dorsal callus

**DIAGNOSIS**

History and physical exam are typically sufficient for diagnosis of hammer toes. Additional tests are available to exclude other conditions.

**HISTORY**
- Location, duration, severity, and rate of progression of foot deformity
- Type, location, duration of pain
  - Patients often relate sensation of lump on plantar aspect of MTP joint.
- Degree of functional impairment
- Improving/exacerbating factors
- Type of footwear and hosiery worn
- Peripheral neurologic symptoms
- Any prior treatment rendered

**PHYSICAL EXAM**
- Note MTP joint hyperextension, PIP joint flexion, and DIP joint extension or flexion.
- Observe any adjacent toe deformities (e.g., hallux valgus, flexion contractures).
- Assess degree of flexibility and reducibility of deformity in both weight-bearing and non-weight-bearing positions.
- Note any hyperkeratosis over the joint, ulcers, clavi (dorsal PIP joint, metatarsal head), adventitious bursa, erythema, or skin breakdown or ulceration.
- Palpate for pain over dorsal aspect of PIP joint or MTP joint.
- Drawer test of MTP joint
- Palpate web spaces to exclude interdigital neuroma.
- Neurovascular evaluation (e.g., pulses, sensation, muscle bulk)

**DIFFERENTIAL DIAGNOSIS**
- Hammer toe: hyperextension of the MTP and DIP joints and plantar flexion of the PIP joint
- Claw toe: dorsiflexion of MTP joint and plantar flexion of the DIP joint
- Mallet toe: fixed or flexible deformity of the DIP joint of the toe
- Overlapping 5th toe
- Interdigital neuroma
- Plantar plate rupture
- Nonspecific synovitis of MTP joint
- Fracture; exostosis
- Arthritis (e.g., rheumatoid, psoriatic)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Not required unless clinically indicated to rule out suspected metabolic or inflammatory
arthropathies (2)[C]: rheumatoid factor, antinuclear antibodies (ANA), HLA-B27 serologies for inflammatory disease
- Weight-bearing x-rays of affected foot in anteroposterior (AP), lateral, and oblique views (2) [C]:
  - AP view superior for assessing transverse plane MTP subluxation or dislocation
  - Lateral view is best for the evaluation of hammer toe.

Follow-Up Tests & Special Considerations
MRI or bone scan if osteomyelitis is suspected

Diagnostic Procedures/Other
- Nerve conduction studies or EMG if neurologic disorder is suspected
- Doppler or plethysmography if impaired circulation and surgery is considered
- Computerized weight-bearing pressure testing is indicated only in setting of neuromuscular deficiencies.

Test Interpretation
Histologic evaluation is not necessary before treatment.

TREATMENT
- Goal of treatment is to relieve symptoms and help patients return to their normal activity level.
- Surgical and nonsurgical interventions are available.
- Mild and asymptomatic cases may not require treatment.

GENERAL MEASURES
Nonsurgical (conservative) treatments include
- Shoe modifications (wider and/or deeper toe box) to accommodate the deformity and decrease the pressure over osseous prominences. Avoid high-heeled shoes (2)[C].
- Toe sleeve or orthodigital padding of the hammer toe prominence (5)[C]
- Metatarsal pads in reducible deformities and crest pads in nonreducible deformities
- Dynamic toe splints for MTP joint subluxations or dislocations with (semi)reducible deformity
- Hammer toe–straightening orthotics or taping to reduce flexible deformities
- Débridement of hyperkeratotic lesions can reduce symptoms. Topical keratolytics may be helpful (2)[C].
- Shoe orthotics mitigates abnormal biomechanics.
- Physical therapy for stretching and strengthening of the toes helps preserve flexibility, which include intrinsic muscle strengthening (short foot exercises).

MEDICATION
For pain relief

First Line
NSAIDs may be helpful in managing symptoms of pain as well as soft tissue and joint inflammation.

ISSUES FOR REFERRAL
If nonsurgical (conservative) treatment is unsuccessful and/or impractical or patient has
combined deformity of MTP joint, PIP joint, and/or DIP joint, then patient may be referred to a podiatric physician/surgeon or orthopedic surgeon.

**SURGERY/OTHER PROCEDURES**

- Surgical procedures for the correction of hammer toes depend on the degree and flexibility of the contracture(s) and related abnormalities.
- Surgical interventions for flexible hammer toes include (1,3,5,6,7)[C]
  - PIP joint arthroplasty or arthrodesis (most common)
  - Flexor tenotomy for reducible or mallet toe deformities with distal ulceration
  - Extensor tendon lengthening/tenotomy/MTP joint capsulotomy
  - Flexor tendon transfer with digital arthrodesis
  - Exostectomy
  - Implant arthroplasty
- Surgical interventions for semirigid/rigid hammer toes include (1,3,5,7)[C]
  - PIP joint resection arthroplasty or arthrodesis
  - Girdlestone-Taylor flexor-to-extensor transfer
  - Metatarsal shortening (Weil osteotomy)
  - Exostectomy
  - Middle phalangectomy (more common in 5th toe)
  - Soft tissue releases/lengthening
  - Diaphysectomy of the proximal phalanx (less common)
  - Phalangeal base resection as part of Hoffman-Clayton procedure for RA mutilans
- Procedures may be performed as isolated operations or in conjunction with other procedures.
- Contraindications for surgery: active infection, inadequate vascular supply, and desire for cosmesis alone

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Obtain radiographs immediately following surgery or at the first postoperative visit; subsequent x-rays as needed
- Full weight-bearing in a postoperative (surgical) shoe or other device based on the procedure(s) performed and the individual patient
- Pinning often used across the MTP joint, which requires limited to non–weight-bearing to the forefoot for 3 to 5 weeks
- Elevate the foot to minimize swelling.
- Return to regular shoe wear after pain is controlled, swelling has subsided, and wounds have healed.
- Role and efficacy of postoperative physical therapy unclear

**Patient Monitoring**
In the absence of complications, the patient should be seen initially within the 1st week following the procedure(s). Frequency of subsequent visits is determined based on the procedure(s) performed and the postoperative course.

**PATIENT EDUCATION**
• Patients should be aware of mild to moderate swelling and plantar foot discomfort that may persist for many (1 to 6) months after surgery and may limit footwear options until resolved.
• MTP joint and PIP joint may remain stiff for extended periods of time.
• “Molding” of the operative toe (assuming the contours of adjacent toes) is common.
• Encourage patients to wear shoes of adequate size with “roomy” (rounded or squared) toe box.

PROGNOSIS
• Nonoperative (conservative) treatment in mild deformities usually alleviates pain; however, the deformity may progress.
• Surgical treatment of flexible hammer toe deformity reliably corrects the deformity and alleviates pain. Recurrence and progression are common, especially if the patient continues to wear ill-fitting shoes.
• Surgical treatment of fixed hammer toe deformity provides reliable deformity correction and pain relief. Recurrence is uncommon.

COMPLICATIONS
• Common complications specific to digital surgery include but are not limited to
  – Persistent edema
  – Recurrence of deformity
  – Residual pain
  – Excessive stiffness
  – Metatarsalgia
• Less common complications include
  – Numbness (e.g., digital nerve palsy)
  – Flail toe
  – Symptomatic osseous regrowth
  – Malposition of toe
  – Malunion/nonunion
  – Infection
  – Sausage toe
  – Vascular impairment (e.g., toe ischemia, gangrene)

Algorithm: Foot Pain

CODES

ICD10

- M20.40 Other hammer toe(s) (acquired), unspecified foot
- M20.41 Other hammer toe(s) (acquired), right foot
- M20.42 Other hammer toe(s) (acquired), left foot

CLINICAL PEARLS

- Hammer toe is a plantar flexion deformity of the PIP joint. Claw toe and mallet toe are additional types of hammer toes.
- Initial management of hammer toe deformity is conservative. Consider surgery if pain persists or the deformity worsens.
- Properly fitting footwear helps minimize recurrence. Patients should be aware of mild to moderate swelling and plantar foot discomfort that may persist for months after surgery and may limit footwear options until resolved.
BASICS

DESCRIPTION
- Common clinical syndrome caused by enterovirus serotypes
- Classic appearance of oral enanthem along with exanthem of hands and feet (classically) and potentially located elsewhere
- Exanthem (rash) may be macular, maculopapular, and/or vesicular.
- Synonym(s): herpangina (when affecting oral mucosa and posterior pharynx)

EPIDEMIOLOGY
- Self-limiting illness resolves in 7 to 10 days.
- Moderately contagious
- Infection is spread by direct contact with nasal secretions, saliva, blister fluid, or stool.
- Infected individuals are most contagious during the 1st week of the illness but may continue to spread illness for days to weeks after. Some exposed individuals (especially adults) may be asymptomatic but still contagious.
- The viruses that cause hand-foot-and-mouth disease (HFMD) can persist for weeks after symptoms have resolved, most commonly in stool, allowing transmission following resolution of symptoms.
- The incubation period is 3 to 7 days (1).

Incidence
- Children <5 years of age are most commonly affected, especially in daycare facilities (1,2).
- Can occur as isolated cases, outbreaks, or epidemics
- Occurs worldwide
- Vertical transmission is possible.
- Most large outbreaks occur in Southeast Asia.

ETIOLOGY AND PATHOPHYSIOLOGY
- HFMD is not the same as foot (hoof) and mouth disease found in cattle, and there is no cross-species infectious concern (3).
- Transmission by the fecal–oral route or contact with skin lesions or oral secretions; caused by viruses that belong to the Enterovirus genus and replicated in the GI tract, most commonly coxsackievirus A16
- Also coxsackieviruses A5, A7, A9, A10, B2, B5, and enterovirus 71

GENERAL PREVENTION
- Hand washing, especially around food handling or diaper changes
- Exclusion of children from group settings during the first few days of the illness in the presence of open lesions in the mouth or on the skin may reduce the spread of infection.
- Hand hygiene measures are effective at reducing transmission.
- Pregnant woman should avoid contact with infected individuals.
DIAGNOSIS

HISTORY
- 1- to 2-day prodrome of fever, anorexia, malaise, abdominal pain, upper respiratory symptoms
- Fever may last 3 to 4 days.
- Maculopapular rash on hands, feet, and mouth. Oral lesions may precede skin.
- Sore throat (follows fever)
- Often history of sick contacts

PHYSICAL EXAM
- Oral enanthem along with tender vesicles becoming ulcers on buccal mucosa, sides of tongue, and palate
- May persist for up to 1 week
- Cutaneous vesicles 3 to 5 mm in diameter start as painful maculopapular eruptions, occur typically on dorsal aspect of fingers and toes.
- May also occur on the palms, soles, buttocks, and groin
- Adults are less likely to have cutaneous findings.
- Nail dystrophies are not uncommon and may persist for weeks following the acute infection.
- Be mindful of central nervous system (CNS) symptoms. Although rare, CNS involvement is possible.

DIFFERENTIAL DIAGNOSIS
- Herpetic gingivostomatitis
- Aphthous stomatitis
- Scabies
- Chickenpox
- Measles
- Rubella
- Scarlet fever
- Roseola infantum
- Fifth disease
- Other enteroviral infections
- Kawasaki disease
- Viral pharyngitis
- Varicella
- Rickettsial infection (RFSF)

DIAGNOSTIC TESTS & INTERPRETATION
Clinical diagnosis is typically adequate.

Initial Tests (lab, imaging)
Culture for responsible virus (virus isolation) can be obtained from oral lesions, cutaneous vesicles, nasopharyngeal swabs, stool, and cerebrospinal fluid (CSF), although not typically performed. Polymerase chain reaction of throat swabs and vesicle fluid is the most efficient test if enterovirus 71 is suspected (3).
TREATMENT

- Symptomatic
- Avoid spicy or acidic foods to limit oral pain.
- IV fluids may be required in more severe cases of dehydration.

MEDICATION

- Symptomatic care using ibuprofen or acetaminophen for pain from oral ulcers or fever
- Soothing mouthwashes (“magic mouthwash”) containing lidocaine do not appear to be superior to placebo and have risk of side effects when absorbed systemically (4)[B].

Pediatric Considerations
Avoid aspirin use in treating febrile illness in children due to concern of Reye syndrome—an encephalopathy associated with aspirin use in viral illness in children.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Patients with CNS manifestations or autonomic dysregulation should require hospitalization.
- Admit those with dehydration unable to maintain adequate oral hydration.

ONGOING CARE

DIET

- Encourage cold liquids (e.g., ice cream, popsicles) to prevent dehydration.
- Avoid acidic, salty, and spicy foods, as they will increase pain.

COMPLICATIONS

- Dehydration most common due to painful oral ulcerations
- CNS involvement (i.e., aseptic meningitis) is a rare complication, although it is on the rise globally.
- Fever >3 days and lethargy are associated with CSF pleocytosis.
- Enterovirus 71 has caused outbreaks and has been implicated in more severe disease associated with CNS infection (5).
- Cardiopulmonary complications include myocarditis, pneumonitis, and pulmonary edema.
- Nail dystrophies (loss of nails, Beau lines) are common.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- B08.4 Enteroviral vesicular stomatitis with exanthem
- B34.1 Enterovirus infection, unspecified
- B08.5 Enteroviral vesicular pharyngitis

CLINICAL PEARLS

- Most common: May to October
- Children <5 years of age tend to have worse symptoms than older children.
- HFMD is the most common cause of mouth sores in pediatric patients.
- Dehydration is a common problem secondary to swallowing aversions.
- Usually self-limiting, resolving in 7 to 10 days
- Careful hand washing to limit dissemination
HEADACHE, CLUSTER
Samuel C. Wang, MD, FAAFP  Michael Dakkak, DO

BASICS

DESCRIPTION
- A primary headache disorder characterized by multiple attacks of unilateral, excruciating, sharp, searing, or piercing pain; typically localized in the periorbital area and temple accompanied by signs of ipsilateral parasympathetic autonomic features, along with restlessness and agitation
- Autonomic symptoms: parasympathetic hyperactivity signs (ipsilateral lacrimation, eye redness, nasal congestion) and sympathetic hypoactivity (ipsilateral ptosis and miosis)
- Patients often pace the floor during an acute attack because lying down seems to exacerbate the pain.
- Symptoms usually remain on the same side during a single cluster attack.
- Individual attacks last 15 to 180 minutes if untreated and occur once every other day to 8 times per day.
- Attacks usually occur in series (cluster periods) that are often seasonal, lasting for weeks or months, separated by remission periods usually lasting months or years.
- About 10–15% of patients have chronic symptoms without remissions (i.e., chronic cluster headache [cCH]).

EPIDEMIOLOGY

Incidence
1-year incidence: 2 to 10/100,000

Prevalence
- Lifetime prevalence: 124/100,000
- Predominant sex: male > female; 2.1:1 overall
- Women often develop earlier in life (20s)
- Mean age of onset: 30 years
- Episodic/chronic ratio: 6:1

ETIOLOGY AND PATHOPHYSIOLOGY
- Complex and incompletely understood
- Possible mechanisms include the following:
  - Posterior hypothalamus activation may trigger an attack by activating trigeminal nociceptive pathways through perivascular activation and increased parasympathetic outflow
  - Alterations in the descending pain modulation network and disordered pain modulation during cluster periods

Genetics
- Usually sporadic: autosomal dominant in 5% of cases; autosomal recessive or multifactorial in other families
- Evidence varies: First-degree relatives carry 5- to 8-fold and second degree 1- to 3-fold
increased relative risk of disease.
>50% with migraine and 18% with CH in family history

**RISK FACTORS**
- Male gender
- Age: 70% onset before age 30 years
- Cigarette smoking or childhood exposure to cigarette smoke
- Family history of CH
- Personal history of head trauma

**COMMONLY ASSOCIATED CONDITIONS**
- Depression (24%)
- Increased risk of suicide secondary to the extreme nature of the pain
- Medication-overuse headache
- Asthma (9%)
- History of migraine, frequently in female patients
- Sleep apnea (30–80%)

**DIAGNOSIS**
- Diagnosis is clinical.
- International Classification of Headache Disorders (3rd edition) criteria
  - At least five attacks of severe or very severe unilateral orbital, supraorbital, and/or temporal pain lasting 15 to 180 minutes if untreated
  - At least one of the following on ipsilateral side:
    - Conjunctival injection and/or lacrimation
    - Nasal congestion and/or rhinorrhea
    - Eyelid edema
    - Forehead and facial sweating/flushing
    - Sensation of fullness in the ear
    - Miosis and/or ptosis
    - Restlessness or agitation during acute attack
  - Attack frequency: one every other day to eight per day for more than half of the time during cluster periods
  - Episodic CH (eCH): at least two cluster periods lasting 7 days to 1 year, separated by a pain-free interval of >1 month (80–90% of cases)
  - cCH: cluster-free interval of <1 month, for at least a year

**HISTORY**
- Episodic periods of headache described as excruciating, unilateral, sharp, searing, or piercing pain, typically localized in the periorbital area
- Eye redness, tearing, nasal congestion, clear rhinorrhea, sweating
- Timing of headaches often circadian in nature, occurring at the same time each day
- Presence of triggers, including vasodilators (e.g., alcohol, nitroglycerin, sildenafil), histamine, or strong odors
- Seasonal pattern of cluster periods, often recurring around the same time of the year
PHYSICAL EXAM
- Patients are usually seen between attacks, so physical exam is often unremarkable.
- Acute distress, crying, screaming, restlessness, and/or agitation during acute attack
- Ipsilateral lacrimation, injected conjunctivae, ptosis, and miosis during acute attack
- Edematous nasal mucosa or rhinorrhea during acute attack

DIFFERENTIAL DIAGNOSIS
- Other trigeminal autonomic cephalgias (e.g., paroxysmal hemicrania, short-lasting unilateral neuralgiform headache attacks with conjunctival injection and tearing [SUNCT], hemicrania continua, hypnic headaches, trigeminal and other facial neuralgias, migraine, temporal arteritis, herpes zoster)
- Secondary CH:
  - Vertebral or carotid artery dissection, brain arteriovenous malformations, intracranial artery aneurysms
  - Pituitary tumors
  - Nasopharyngeal carcinoma
  - Cavernous hemangioma
  - Meningiomas/carcinomas/metastases

DIAGNOSTIC TESTS & INTERPRETATION
- Diagnosis is primarily clinical.
- Diagnosis is often delayed (>40% report 5-year delay in diagnosis).
- Consider neuroimaging (MRI/CT head and vascular imaging of brain) if:
  - Abnormal neurologic exam
  - Suspect secondary CH
  - “Red flag” headache symptoms are present

TREATMENT
Many of the medications discussed in the following section are used off-label in the treatment of CH.

GENERAL MEASURES
- Avoid major changes in sleep habits.
- Stop smoking.
- Avoid use of alcohol during cluster period.
- Avoid extreme changes in altitude due to changes in oxygen levels.
- Avoid exposure to chemical agents/solvents or other known triggers for the patient.

MEDICATION
- Avoid pain medications, especially narcotic analgesics, for acute attacks.
- Goal is abortion of acute attack and transitional prophylaxis for expected duration of the cluster period.
- Long-term prophylaxis used for cCH
- Assess cardiovascular risk before instituting a vasoactive drug, such as triptans or ergot derivatives.
**First Line**
- For acute attacks:
  - Oxygen: 100% at 7 to 15 L/min via nonrebreather mask or demand valve oxygen mask while sitting or standing provide relief within 15 minutes. High flow used if resistant to lower-flow oxygen; excellent side-effect profile (1,2)[A]

**ALERT**
Avoid high-flow oxygen in patients with severe chronic obstructive pulmonary disease

- Sumatriptan
  - 6 mg SC, max 2 times per day with at least 1 hour between injections is most effective medication for acute attacks; NNT = 2.4 and 3.3 for headache relief and pain free in 15 minutes, respectively
  - Nasal spray: 20 mg; may repeat in 2 hours, max dose 40 mg/24 hr; NNT = 3.2 for headache relief at 30 minutes (1,3)[A]

- Zolmitriptan
  - Nasal spray: 5- and 10-mg dosage both effective; may repeat in 2 hours, max 2 times per day; NNT = 12 and 4.9 for headache relief in 15 minutes for 5 and 10 mg, respectively
  - Tablet: 5- and 10-mg dosage both effective; may repeat in 2 hours, max dose 10 mg/24 hr; NNT = 6.7 and 4.5 for headache relief in 30 minutes for 5 and 10 mg, respectively (1,3)[B]

**ALERT**
Triptans are contraindicated in ischemic cardiac disease, stroke, uncontrolled hypertension, Prinzmetal angina, basilar migraine, hemiplegic migraine, ischemic bowel disease, and peripheral vascular disease.

- For prophylaxis:
  - Used at start of cluster period to prevent and shorten further attacks. Start as soon as possible
  - Galcanezumab: 300 mg SC injection q month until cluster period ends. Only FDA approved medication for eCH prophylaxis. Most common side effects are nasopharyngitis and local injection site reaction and pain. NNT = 5.2 (4)[B]
  - Verapamil: Start at 80 mg TID and increase by 80 mg/week to 480 mg and then 80 mg every 2 weeks if needed. Short- or long-acting equivalent. Most patients respond to daily dose of 200 to 480 mg, but up to 960 mg/day may be needed; NNT = 1.2 (5)[C]

**ALERT**
ECG monitoring is required for verapamil dose >400 mg/day because of risk of bradycardia, prolonged PR interval, RBBB, or complete heart block. Avoid grapefruit juice due to CYP3A4 inhibition (5)[C].

**Second Line**
- For acute attacks:
  - Lidocaine/cocaine: 10 mg (1 mL) of lidocaine or 40 to 50 mg of 10% cocaine intranasal. No well-controlled randomized controlled trials (RCTs) done. Most common side effects are nasal congestion and unpleasant taste.
  - Octreotide: SC 100 μg. Can be considered in patients when triptans are contraindicated. Main side effect is gastrointestinal upset.
For prophylaxis
- Melatonin: 10 mg regular-release tablet in late evening showed reduction in headache frequency versus placebo in small RCT. No side effects were reported.
- Lithium: Start 300 mg BID; titrate to therapeutic range of 0.4 to 0.8 mEq/L. Can increase to 300 mg TID in 1 week and then as tolerated. Two RCTs done; one was positive, one was negative. Must monitor drug levels, liver, renal, and thyroid function. Caution with nephrotoxic drugs, diuretics. Monitor for central nervous system side effects.
- Capsaicin: 0.025% ipsilateral nostril for 7 days showed benefit in one small RCT.

ISSUES FOR REFERRAL
Consider a neurology or headache center referral for refractory or complicated patients.

ADDITIONAL THERAPIES
Transitional prophylaxis:
- Used to reduce attack frequency until longer term preventive treatment becomes effective.
  Longer term maintenance agents are started concurrently.
- Steroids: Several open studies suggested benefit but no rigorous trials to prove efficacy.
  Studies support 60 to 80 mg/day (initial dose) prednisone with a taper no longer than 18 days to avoid side effects; adverse effects for short-term use: insomnia, psychosis, hyponatremia, edema, hyperglycemia, peptic ulcer (5)[C]
- Suboccipital steroid injection: 3.75 mg of cortivazol injected into the suboccipital area on the ipsilateral side of the headache; single injection or series of three injections, given 48 to 72 hours apart, reduces attack frequency during cluster period when used as add-on therapy to verapamil; NNT = 2.5 (6)[B].
- Dihydroergotamine (DHE): 1 mg injected SC/IM BID–TID for up to a week. Controlled studies are lacking (5)[C].

ALERT
Ergotamines are contraindicated in patients with cardiovascular disease and cannot be used with triptans; black box warning against using concomitantly with 3A4 inhibitors, such as protease inhibitors and macrolide antibiotics

Pregnancy Considerations
- Collaboration between headache specialist, obstetrician, pediatrician, and lactation specialist is recommended.
- Patient should be informed of limited data on treatment efficacy versus safety.
- For acute treatment, oxygen is most appropriate first-line therapy. Intranasal lidocaine (pregnancy Category B) can be used as second-line therapy and has no adverse effects with breastfeeding (7)[C].
- For transitional prophylaxis, steroids (pregnancy Category C/D) can be used, but systemic use should be avoided in 1st trimester (7)[C].
- As preventive therapy, verapamil (pregnancy Category C) remains the preferred option. Use of SC or intranasal sumatriptan and zolmitriptan (pregnancy Category C) should be limited as much as possible. Avoid ergotamines (pregnancy Category X) (7)[C].

SURGERY/OTHER PROCEDURES
- No evidence for Botox or hyperbaric oxygen treatment
- Surgery may be considered only for patients who are refractory to, or have contraindications
to, medical therapy.

- Various techniques focus on stimulation or ablation of segments of trigeminal nerve root and sphenopalatine ganglion. Techniques are often invasive and/or involve implantation of devices. Other techniques are aimed at decreasing pain and inflammation surrounding the greater occipital nerve.
- Neurostimulation
  - Multicenter RCT showed efficacy of sphenopalatine ganglion stimulation (SPG) compared to sham treatment; CINTHA Trial ongoing
  - Bilateral occipital nerve stimulation (ONS) has been shown to reduce severity and attack frequency in cCH patients.
  - Deep brain stimulation (DBS) of the hypothalamus has shown a positive response rate but carries risks of stroke, hemorrhage, and death.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Intractable, severe pain
- Suicidal ideation

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Anticipate cluster bouts and initiate early prophylaxis.
- Monitor for depression and suicidal ideation, especially in those with cCH.
- Watch for adverse medication responses and side effects, such as unmasking of underlying cardiovascular disorder, when using medications to treat CH.

PROGNOSIS

- Unpredictable but often chronic course
- With increasing age, attack frequency often decreases.
- Possibility of transformation of eCH to cCH

COMPLICATIONS

- Depression and suicide
- Side effects of medication, including unmasking of coronary artery disease

REFERENCES

ADDITIONAL READING

CODES

ICD10

- G44.009 Cluster headache syndrome, unspecified, not intractable
- G44.019 Episodic cluster headache, not intractable
- G44.029 Chronic cluster headache, not intractable

CLINICAL PEARLS

- CHs are uncommon but very disabling.
- Patients are often agitated and restless during the acute attack.
- High-flow oxygen and triptans, not narcotics, are first-line therapy for acute attacks.
- Among triptans, injected forms are more effective than nasal sprays, which are more effective than oral tablets.
- Abortive, transitional, and prophylactic treatments must all be considered.
HEADACHE, MIGRAINE
Karly Pippitt, MD • Seniha Ozudogru, MD

BASICS

DESCRIPTION
Recurrent headache disorder manifesting in attacks lasting 4 to 72 hours. Typical characteristics are unilateral location, pulsating quality, moderate to severe intensity, aggravation by physical activity, and association with nausea and/or photophobia and phonophobia (1).

Most frequent subtypes of migraine (1):
- Without aura (common migraine): defining >80% of attacks, often associated with nausea, vomiting, photophobia, and/or phonophobia
- With aura (classic migraine): visual or other types (motor, sensory or brainstem symptoms, including previously known as basilar or hemiplegic migraine) of fully reversible neurologic phenomenon develops gradually over 5 minutes and lasts up to 60 minutes
- Chronic migraine: Migraine attacks are >15 headache days/month, >4 hours/day, for at least 3 months.
- Menstrual-related migraine: associated with onset of menstrual period

Rare but important subtypes (1):
- Status migrainosus: debilitating migraine lasting >72 hours
- Prolonged aura: aura symptoms lasting more than 60 minutes (can last up to 7 days)
- Retinal: repeated attacks of monocular visual disturbance, including scintillations, scotomata, or blindness, associated with migraine headache
- Acephalagic migraine (migraine aura without headache): typical aura symptoms not followed by a migraine headache

EPIDEMIOLOGY
Female > male (3:1)

Prevalence
- Affects >28 million Americans
- Adults: women 18%; men 6%

ETIOLOGY AND PATHOPHYSIOLOGY
- Trigeminovascular hypothesis: Hyperexcitable trigeminal sensory neurons in brainstem are stimulated and release neuropeptides, such as substance P and calcitonin gene-related peptide (CGRP), leading to vasodilation and neurogenic inflammation.
- Cortical spreading depression: Mainly accepted hypotheses for migraine with aura; change in electrical activity with reduction of blood flow, leading to aura

Genetics
- >80% of patients have a positive family history.
- Familial hemiplegic migraine has been shown to be linked to chromosomes 1, 2, and 19 (1).

RISK FACTORS
- Family history of migraine
Female gender
- Stress
- Menstrual cycle, hormones
- Sleep pattern disruption
- Diet: skipped meals (48%), alcohol (32%), chocolate (20%), cheese (13%), caffeine overuse (14%), monosodium glutamate (MSG) (12%), and artificial sweeteners (e.g., aspartame, sucralose)
- Medications: estrogens, vasodilators

**GENERAL PREVENTION**
- Avoid precipitants of attacks.
- Lifestyle modifications are the cornerstone of prevention: sleep hygiene, stress management, healthy diet, adequate hydration, and regular exercise.
- Biofeedback, education, and psychological intervention
- Prophylactic medication if attacks are frequent, severely debilitating, or not controlled by acute interventions

**COMMONLY ASSOCIATED CONDITIONS**
- Depression, anxiety, posttraumatic stress disorder
- Sleep disturbance (e.g., sleep apnea)
- Cerebral vascular disease
- Seizure disorders
- Irritable bowel syndrome
- Obesity
- Medication overuse headache (MOH)
- Childhood trauma

**DIAGNOSIS**
Migraine is a clinical diagnosis; thorough history and neuro examination are usually all that are necessary.

**HISTORY**
- Validated migraine screening tool: ID MigraineTM (2)
- In the last 3 months did you have the following symptoms with your headaches:
  - Nauseated or sick to your stomach?
  - Light bothered you (more than when you didn’t have a headache)?
  - Headaches limited your ability to work, study, or do what you needed for a day?
- Answering yes to 2 questions is 81% probability of migraine; answering yes to 3 questions increases probability of migraine to 93% (2)
- Headache usually begins with mild pain escalating into unilateral (30–40% bilateral) throbbing (40% nonthrobbing) pain lasting 4 to 72 hours. If headache is sidelocked, and never shifts sides or is bilateral, should prompt evaluation for alternative diagnosis.
- Intensified by movement and associated with systemic manifestations: nausea (87%), vomiting (56%), diarrhea (16%), photophobia (82%), phonophobia (78%), muscle tenderness (65%), light-headedness (72%), and vertigo (33%)
- May be preceded by aura
– Visual disruptions are most common—scotoma, hemianopsia, fortification spectra, geometric visual patterns, and occasionally hallucinations
– Somatosensory disruption in face or arms
– Speech difficulties

• Obtain headache diary: episodes per month, HA days per month, frequency, and amount and effect of medications used.
• Migraine disability assessment (MiDAS) is a useful tool to assess level of disability and correlates well with headache diaries.
• Identify possible triggers (e.g., stress, sleep disturbance, food, caffeine, alcohol).

PHYSICAL EXAM
Neurologic exam should be performed including funduscopy; abnormalities consistent with other causes for severe headaches may include:
• Gait abnormalities or other cerebellar findings
• Loss of gross and/or fine motor function
• Altered mental status including possible hallucinations (visual, auditory, olfactory)
• Short-term memory loss
• Papilledema

DIFFERENTIAL DIAGNOSIS
• Other primary headache syndromes (e.g., idiopathic intracranial hypertension [IIH], trigeminal autonomic cephalalgia [TAC])
• Secondary headaches: MOH, tumor, infection, vascular pathology, or illicit drug use
• If focal neurologic signs/symptoms are present, consider transient ischemic attack (TIA) or stroke.

DIAGNOSTIC TESTS & INTERPRETATION
Neuroimaging is appropriate ONLY with suspicious symptomatology and/or an abnormality on physical examination (3). Other red flags include the following:
• New onset in patient >50 years of age
• Change in established headache pattern
• Atypical pattern or unremitting/progressive neurologic symptoms
• Prolonged or bizarre aura
• CT of the head with and without contrast is indicated only if “Red Flag” Symptoms. MRI/MRA if vascular lesions suspected.
• Electroencephalogram is not indicated unless evaluating loss of consciousness or altered mental status.

Pediatric Considerations
nonsteroidal anti-inflammatory drugs (NSAIDs) and triptans are effective for the acute treatment of children and adolescents with migraine; NSAIDs are first line. Triptans may have better efficacy than NSAIDs but can have more side effects. Rizatriptan is Food and Drug Administration (FDA) approved for children aged 6 and older; sumatriptan succinate-naproxen sodium, almotriptan, and zolmitriptan nasal spray FDA approved in kids aged 12 years and older (4)[A].

Pregnancy Considerations
• Frequency may decrease in 2nd and 3rd trimesters.
For new onset headaches in pregnancy, pre-eclampsia and venous sinus thrombosis should be considered as possible diagnoses.

Nonpharmacologic methods are preferred.

No treatment drug has FDA approval in pregnancy and breastfeeding.
- Acetaminophen, sumatriptan (except first trimester), antiemetics, and short-acting opioids can be considered for acute headaches during pregnancy.
- Ergotamines are contraindicated in pregnancy.
- Avoid herbal remedies.
- Propranolol is effective for prophylaxis during pregnancy and lactation.

## TREATMENT

### GENERAL MEASURES

- Most patients manage attacks with self-care.
- Cold compresses to area of pain
- Withdrawal from stressful surroundings.
- Consistent sleep hours desirable
- See also “General Prevention”

### MEDICATION

- First-line abortive treatments
  - Mild to moderate attacks:
    - Acetaminophen is effective and, when combined with metoclopramide, has relief rates similar to triptans (5)[A].
    - NSAIDs are inexpensive and effective in up to 60% of cases (5)[B].
    - Aspirin-acetaminophen–caffeine (Excedrin Migraine) is an inexpensive, OTC treatment with efficacy higher than its components (5)[B].
  - Moderate to severe attacks:
    - Triptans when OTC agents fail for mild-moderate attacks OR first line for moderate-severe attacks
    - All triptans have similar efficacy/tolerability, but patients often respond better to one triptan over another (5)[C]. Suggested initial doses:
      - Sumatriptan 100 mg PO; 6 mg subcut; 20 mg intranasal. Subcut is most rapid.
      - Rizatriptan 10 mg PO (dose is 5 mg if patient is taking propranolol for prophylaxis)
      - Naratriptan 2.5 mg PO
      - Zolmitriptan 2.5 mg PO; 5 mg intranasal
      - Frovatriptan 2.5 mg PO
      - Eletriptan 40 mg PO
        - 44–77% of patients taking triptans report complete pain relief within 2 hours.
        - Frovatriptan and naratriptan have slow onset but long half-lives—best for people with long migraine duration/recurrence.
  - Combination triptan and NSAID: Sumatriptan 85 mg/naproxen 500 mg PO at onset of headache show decrease in recurrence over either alone.
  - Antiemetics: Dopamine antagonists are excellent adjunctive medications (5)[B].

- Contraindications to treatments
  - Avoid triptans and ergots in coronary artery or peripheral vascular disease and uncontrolled...
hypertension.
– Do not combine triptans or use with ergots or monoamine oxidase inhibitor (MAOIs).
– Avoid opioids or butalbital in patients with frequent migraines.

● Precautions
– Frequent use of acute-treatment drugs can result in MOH (especially OTC analgesics, triptans, butalbital).
– Triptans common adverse reactions include chest pressure, flushing, weakness, dizziness, feeling of warmth, and paresthesias. Okay to try another triptan; this is not a contraindication.

● Second-line abortive treatment
– Dihydroergotamine: drug of choice in status migrainosus and triptan resistance.
– Opiate use can contribute to MOH with use as few as 8 days per month.

● First-line preventive treatment (6)[A]
– Should not be limited to pharmacologic agents; trigger reduction, biofeedback, relaxation techniques, and CBT have evidence of efficacy.
– Lifestyle modifications should be recommended for all migraine sufferers.
– ~38% of migraine patients need preventive therapy, but only 3–13% use it. Trial and error is needed to determine optimal therapy. May achieve more benefit with use of more than one preventive agent.

● The American Migraine Prevalence and Prevention Study suggests prophylactic treatment when:
– Quality of life is severely impaired.
– ≥6 headache days per month, ≥4 headache days per month of moderate severity, or ≥2 headache days per month of severe impairment.
– Migraines do not respond to abortive treatment.
– Frequent, very long, or uncomfortable auras occur.

● Preventive treatment of migraine: Divalproex, topiramate, metoprolol, and propranolol are effective in reducing frequency/severity. Also consider amitriptyline and venlafaxine; lisinopril and candesartan are other options (6)[A].
– NSAIDs appear effective for prevention in people with predictable triggers (menses, etc.) but pose a risk for MOH.
– Monoclonal antibodies: Erenumab (Aimovig), a complete CGRP receptor antagonist, FDA-approved in 5/2018; Ajovy (fremanezumab-vfrm) and Emgality (galcanezumab-gnlm) partial CGRP receptor antagonist, FDA approved 11/2018; for use in episodic or chronic migraine prevention.

● For treatment of chronic migraine, botulinum toxin A (Botox) significantly reduces frequency of headache days by 2 days relative to placebo (6)[A].

ISSUES FOR REFERRAL
● Obscure diagnosis, concomitant medical conditions, significant psychopathology
● Unresponsive to usual treatment

COMPLEMENTARY & ALTERNATIVE MEDICINE
● Riboflavin (vitamin B<sub>2</sub>): 400 mg/day (6)[B]
● Magnesium: 400 mg/day (6)[B]
● MIG-99 (Feverfew): 6.25 mg TID (6)[B]
● Histamine subcut: 1 to 10 ng twice weekly (6)[B]
● Melatonin: 3 mg nightly
● Acupuncture is as effective as prophylactic drug treatment and has fewer adverse effects.
● Butterbur use is controversial. Although effective, recent safety concerns in Europe limit its use (6)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
● Admission is rarely necessary, unless diagnosis is not clear or in the case of status migrainosus.
● Hydration and antiemetics are central to management. Various IV dihydroergotamine protocols can be found.
● Discharge criteria judgment based on patient’s overall clinical status and patient’s ability to tolerate PO medications

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
● Early intervention is key at the onset of an attack.
● Preventive treatment to decrease frequency and severity of attacks, make acute treatments more efficacious, and minimize adverse drug reactions
● Prophylactic medications can be recommended to any patient but should be offered if attacks are frequent, severely debilitating, or not controlled by acute interventions.

Patient Monitoring
● Like many chronic conditions, patients suffering from migraine headaches tend to benefit from regular office visits. Quarterly or even more frequent appointments may be necessary when headaches are suboptimally controlled.
● Monitor frequency of attacks, pain behaviors, and medication usage via headache diary.
● Encourage lifestyle modifications. Counsel patients and manage expectations.
● Regular lab monitoring is not recommended, but given that migraine (especially with aura) is a risk factor for stroke, lipid assessment and other harm reduction such as tobacco cessation are reasonable.
  – Women with migraine with aura should avoid estrogen-containing drugs due to increased risk of stroke (2)[A].

PATIENT EDUCATION
Patient education is central to the treatment of migraines.
● Trigger identification and modification can significantly improve headache frequency.
● Setting expectations is also critical, especially with regard to prophylactic medications where success is often defined as a reduction of 50% in severity or frequency of headaches.

PROGNOSIS
● With increasing age, there may be a reduction in severity, frequency, and disability of attacks.
● Most attacks subside within 72 hours.

COMPLICATIONS
● Status migrainosus (>72 hours)
● MOH: headache 10 or more days per month for >3 months due to regular overuse of an acute
or symptomatic headache medication; likelihood with butalbital > opiates > triptans > NSAIDs

Cerebral ischemic events (rare)

SEE ALSO

Algorithm: Headache, Chronic

CODES

ICD10
- G43.909 Migraine, unsp, not intractable, without status migrainosus
- G43.109 Migraine with aura, not intractable, w/o status migrainosus
- G43.409 Hemiplegic migraine, not intractable, w/o status migrainosus

CLINICAL PEARLS

- Migraine is a chronic headache disorder of unclear etiology often characterized by unilateral, throbbing headaches that may be associated with additional neurologic symptoms.
- Consider nonspecific analgesics and antiemetics for mild attacks; migraine-specific treatments for more severe attacks
- Avoid opiates and barbiturates as well as frequent (>8 per month) use of triptans or NSAIDs to
avoid creating a MOH.

- All patients should be counseled on lifestyle modifications and trigger identification.
- In those with frequent or highly debilitating migraines, prophylactic treatment should be encouraged.
HEADACHE, TENSION
Assim AlAbdulKader, MD, MPH ● Jason Chao, MD, MS

BASICS
DESCRIPTION
- Typically characterized by bilateral mild to moderate, nonthrobbing head pain or pressure, without other associated symptoms
- Three types of tension-type headache (TTH):
  - Infrequent episodic TTH: <1 day per month
  - Frequent episodic TTH: ≥1 but <15 days per month
  - Chronic TTH: ≥15 days per month for >3 months
- TTHs replaced older terms: muscle contraction headache, stress or tension headache, and psychogenic headache

EPIDEMIOLOGY
The most common type of primary headache, and the second most prevalent disorder in the world

Prevalence
- Peak age of prevalence in the United States: the 4th decade
- Lifetime prevalence: men (69%); women (88%)
- Prevalence of episodic TTH decreases with age, whereas the prevalence of chronic TTH increases with age.

ETIOLOGY AND PATHOPHYSIOLOGY
- Multifactorial: peripheral and/or central mechanisms
- Activation of peripheral nociceptors leads to myofascial pain in episodic TTH.
- Prolonged stimulation of nociceptors sensitizes the central pain pathways leading to chronic TTH.
- Nitric oxide may play an important role in TTH.

Genetics
An increased genetic risk has been suggested by studies, particularly for chronic TTH.

RISK FACTORS
Associated with triggers/precipitating factors:
- Stress (mental or physical): the most common
- Change in sleep regimen
- Skipping meals
- Certain foods (caffeine, alcohol, chocolate)
- Dehydration
- Physical exertion
- Environmental factors (sun glare, odors, smoke, noise, lighting)
- Poor or sustained posture
- Female hormonal changes
Medications (e.g., nitrates, selective serotonin reuptake inhibitors (SSRIs), antihypertensives)

Overuse of abortive headache medication

GENERAL PREVENTION

Identify and avoid triggers/precipitating factors.
Minimize physical and emotional stress.
Encourage relaxation techniques: biofeedback, relaxation therapy, and physical therapy.
Consider counseling/psychotherapy.

COMMONLY ASSOCIATED CONDITIONS

- 83% of patients with migraine headaches also suffer from TTHs.
- Debatable: increased prevalence of comorbid anxiety and depression

DIAGNOSIS

HISTORY

Obtain a thorough pain history to rule out other headache disorders, including onset, location, radiation, quality of pain, severity, associated symptoms; concurrent medical conditions and medications; and recent trauma or other procedures.

Diagnosis is based on clinical assessment.

Pain may be described in many ways, such as “dull,” “bandlike,” “pressure.”

- Diagnostic criteria by the International Headache Society (ICHD-3) (1):
  - Episodic TTH: ≥10 headache episodes that meet all of the following criteria:
    - Headache lasting 30 minutes to 7 days
    - At least two of the following:
      - Bilateral location
      - Pressing/tightening (nonpulsating) quality
      - Mild or moderate intensity
      - Not aggravated by routine physical activity
    - Not associated with
      - Nausea or vomiting
    - No more than one of photophobia or phonophobia
  - Headache not due to another ICHD-3 diagnosis
  - Chronic TTH: ≥15 days per month (on average) for >3 months that meet all of the following criteria:
    - Headache lasting hours to days, or unremitting
    - At least two of the following:
      - Bilateral location
      - Pressing/tightening (nonpulsating) quality
      - Mild or moderate intensity
      - Not aggravated by routine physical activity
    - Both of the following:
      - No more than one of photophobia, phonophobia, or mild nausea
      - Neither moderate or severe nausea nor vomiting
  - Headache not due to another ICHD-3 diagnosis

PHYSICAL EXAM
Usually unremarkable

Head and neck: palpation of myofascial tissues for pericranial muscle tenderness

Neurologic exam: mental status, pupillary responses, motor-strength testing, deep tendon reflexes, sensation, cerebellar function, gait testing, signs of meningeal irritation

Differential Diagnosis

- Migraine headache
- Cluster headache
- Head trauma
- Subarachnoid hemorrhage (SAH)
- Subdural hematoma
- Unruptured vascular malformation
- Ischemic cerebrovascular disease
- Temporal arteritis
- Arterial hypertension (HTN)
- Cerebral venous thrombosis
- Benign intracranial HTN
- Intracranial neoplasm, infection, or meningitis
- Low cerebrospinal fluid pressure
- Medication (nonprescription analgesic dependency, nitrates)
- Caffeine dependency
- Metabolic disorders (hypoxia, hypercapnia, hypoglycemia)
- Toxic effects from drugs or fumes
- Temporomandibular joint syndrome
- Eyes: glaucoma, refractive errors
- Sinusitis or middle ear infection
- Cervical spondylosis
- Severe anemia or polycythemia
- Uremia and hepatic disorders
- Paget disease of bone

Diagnostic Tests & Interpretation

- Most primary headaches with typical features do not require lab testing or diagnostic imaging.
- Labs and neuroimaging (computed tomography [CT] or magnetic resonance imaging [MRI]) should be considered when a secondary cause is suspected:
  - Atypical pattern of headache (does not fit specific category such as migraine, cluster, or tension)
  - Rapid increase in frequency
  - Unexplained focal neurologic findings
  - New onset after age 40 years
  - Sudden onset or worsening with exertion
- MRI with and without contrast is the test of choice. However, head CT is preferred in emergency settings.
- If acute SAH is suspected, head CT should be performed before lumbar puncture (1)[B].
TREATMENT

- Nonsteroidal anti-inflammatory drugs (NSAIDs), aspirin, or acetaminophen are effective for short-term relief of episodic TTH (2),(3)[B].
- Amitriptyline should be considered first line for prophylaxis of chronic TTH (2),(3)[B].

GENERAL MEASURES
Relief measures: relaxation routines; rest in quiet, dark room; hot bath or shower; massage of back of neck and temples

MEDICATION
Choice of simple analgesics is based on patient-specific parameters:
- NSAIDs may be more effective than acetaminophen for episodic TTH (2)[C]: Ibuprofen and naproxen may be preferred due to better gastrointestinal (GI) tolerability.
- Acetaminophen should be considered for patients taking warfarin, unable to tolerate NSAIDs, or allergic to aspirin or NSAIDs.

First Line
- For acute treatment in episodic TTH:
  - NSAIDs:
    - Ibuprofen (Motrin, Advil): 200 to 400 mg; may repeat q8h PRN (max 3.2 g/day)
    - Naproxen sodium (Naprosyn): 220 to 550 mg BID PRN (max 1,250 mg base per day)
    - Contraindications: aspirin or NSAID allergy or bronchospasm, renal disease, bleeding disorders, increased risk of cardiovascular events (myocardial infarction [MI], stroke, new onset or worsening of HTN)
    - Drug interactions: antihypertensives, anticoagulants, antiplatelet drugs, aspirin, lithium, methotrexate
    - Adverse effects: epigastric distress, peptic ulcer
  - Aspirin: 650 to 1,000 mg; may repeat q6h PRN (max 4 g/day):
    - Contraindication: aspirin or NSAID allergy or bronchospasm, bleeding disorders, peptic ulcer
    - Drug interactions: antiplatelet drugs, angiotensin-converting enzyme inhibitors, β-blockers, corticosteroids, NSAIDs, sulfonyleureas
    - Adverse effects: GI irritation/bleeding, thrombocytopenia
  - Acetaminophen (Tylenol): 1,000 mg; may repeat q6h PRN (max 3 to 4 g/day):
    - Adverse effects (rare): rash, pancytopenia, liver damage
    - Precaution: hepatic impairment, consumption of ≥3 per day alcoholic beverages
- For prophylaxis in frequent episodic and chronic TTH:
  - Tricyclic antidepressants (TCAs): Amitriptyline [Elavil]: Start at 10 mg, may slowly up-titrate to 100 mg QHS.
    - Not Food and Drug Administration (FDA) approved for chronic TTH
    - Consider if patient has depression, anxiety, or insomnia.
    - Contraindications: acute recovery phase of MI, use of monoamine oxidase inhibitors (MAOIs) within 14 days
    - Drug interactions: clonidine, MAOIs, quinolone antibiotics, SSRIs, sympathomimetics,azole antifungals, valproic acid
    - Adverse effects: weight gain, drowsiness, dry mouth, tachycardia, heart block, blurred
vision, urinary retention, seizure

Second Line

- For acute treatment in episodic TTH:
  - Caffeine combinations: 130 mg caffeine with 500 mg acetaminophen and/or 500 mg aspirin q6h PRN (2)[C]
  - Ketorolac: 60 mg IM once, for severe episodes
  - Opioids (e.g., codeine), butalbital, or their combination: not recommended. Consider secondary causes of headache or secondary gain such as drug-seeking behavior for personal use or diversion/sale.

- For prophylaxis in frequent episodic and chronic TTH:
  - Mirtazapine: 15 to 30 mg/day (not FDA approved for chronic TTH) (2),(3)[B]

**ALERT**

Use of abortive agents >2 days/week may lead to medication-overuse headaches; must withdraw acute treatment to diagnose

**Pediatric Considerations**

Aspirin and antidepressants are contraindicated.

**ADDITIONAL THERAPIES**

- The combination of stress management therapy and a TCA (amitriptyline) may be most effective for chronic TTH.
- Topiramate: 100 mg/day (limited clinical evidence for prevention of chronic TTH; not FDA approved for chronic TTH)
- Alternative TCAs: limited evidence of benefit (4)[B]
  - Nortriptyline (Pamelor): 25 to 50 mg/day (mild-moderately sedating, causes weight gain)
  - Protriptyline (Vivactil): 25 mg/day (nonsedating, causes weight loss)
- Tizanidine: conflicting clinical evidence for use in chronic TTH, thus should not be considered

**SURGERY/OTHER PROCEDURES**

- Trigger point lidocaine injections: may reduce headache frequency in frequent episodic or chronic TTH (5)[B].
- Botulinum toxin injection: conflicting clinical evidence for use in chronic TTH, thus should not be considered

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Tiger Balm or peppermint oil (not FDA approved for TTH) applied topically to the forehead may be effective for episodic TTH (6)[B].
- Cognitive-behavioral therapy may be helpful (2),(6)[C].
- Electromyography (EMG) biofeedback may be effective and is enhanced when combined with relaxation therapy (2),(5)[C].
- Physical therapy, including positioning, ergonomic instruction, massage, transcutaneous electrical nerve simulation, and application of heat/cold may help.
- Chiropractic spinal manipulation has equivocal evidence in the management of episodic and chronic TTH (6)[B].
- Acupuncture may decrease symptoms frequency; NNT = 3 to have at least 50% reduction in headache frequency, compared to routine care (7)[B]
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Typical symptoms usually managed in the outpatient setting. However, red flag symptoms may prompt emergent evaluation (thunderclap onset, fever and meningismus, papilledema with focal signs) or urgent management (temporal arteritis, relevant systemic illness, papilledema without focal signs, elderly patient with new headache and cognitive changes).

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Keep headache diary to identify triggers, monitor progress, and prevent medication-overuse headache.
- Regulate sleep schedule.
- Regular exercise

DIET
- Identify and avoid dietary triggers.
- Regulate meal schedule.

PATIENT EDUCATION
- National Headache Foundation: https://www.headaches.org/resources
- Family Doctor by AAFP: https://familydoctor.org/condition/headaches

PROGNOSIS
- Usually follows a chronic course when life stressors are not changed
- Most cases are intermittent and decreases with age.

COMPLICATIONS
- Lost days of work and productivity (more with chronic TTH)
- Cost to health system
- Medication-overuse headache
- Dependence/addiction to narcotic analgesics
- GI bleeding from NSAID use

REFERENCES

SEE ALSO
Algorithm: Headache, Chronic

CODES
ICD10
- G44.209 Tension-type headache, unspecified, not intractable
- G44.219 Episodic tension-type headache, not intractable
- G44.229 Chronic tension-type headache, not intractable

CLINICAL PEARLS
- Typically characteristics include bilateral mild to moderate, nonthrobbling head pain or pressure, without other associated symptoms.
- Consider secondary causes and obtain further testing, such as neuroimaging, if there are unexplained focal signs, atypical presentation, late onset (>50 years of age), or when usual treatment fails.
- Medication-overuse headaches can be minimized by limiting use of abortive agents to no more than 2 days/week.
- Chronic TTH is difficult to treat, and these patients are more likely to develop medication-overuse headache.
- Avoid the use of opioids or butalbital-containing medications as first-line treatment for recurrent headaches.
HEARING LOSS
Daniel Frasca, DO  Dana R. Jenkins, DNP

BASICS

DESCRIPTION
- Decrease in the ability to perceive and comprehend sound. It can be partial, complete, unilateral, or bilateral.
  - Typically defined as a deficit >25 dB
- Types of hearing loss include conductive hearing loss (CHL or air–bone gap), sensorineural hearing loss (SNHL), or mixed hearing loss.
- System(s) affected: auditory; outer and middle ear (CHL) or inner ear, auditory nerve, and/or brainstem (SNHL).
- Sudden hearing loss is defined as rapid-onset, subjective sensation of hearing impairment in one or both ears (1).

EPIDEMIOLOGY
- All ages affected; common in children (CHL) and elderly (SNHL).
- Usually more severe at an earlier age in men.

Incidence
- Increases with age
- Sudden sensorineural hearing loss (SSHL) occurs in 5 to 27 per 100,000 persons per year.

Prevalence
World Health Organization estimates that 538 million people affected worldwide

Geriatric Considerations
- 24.7% of 60 to 69 year olds in United States have bilateral speech-frequency hearing loss.
- ~80% of people aged >85 years have hearing loss.
- Hearing aids are underutilized.
- Loss of communication is a source of emotional stress and a physical risk for the elderly.
- Consider auditory rehabilitation (facing people when talking, improving lighting, minimizing background noise).

Pediatric Considerations
- Significant hearing loss at birth and infancy can lead to speech, language, and cognitive delays. Early diagnosis and treatment improves outcome.
  - 60% of childhood hearing loss is secondary to preventable causes.
- Congenital hearing loss
  - 1 to 6/1,000 infants have hearing loss.
  - Mandatory screening in >97% of newborns with otoacoustic emission (OAE) and auditory brainstem response (ABR) testing.
- Audiologic testing after major intracranial infection (meningitis).

Pregnancy Considerations
- Otosclerosis can worsen during pregnancy.
• Maternal infections can cause permanent pediatric hearing loss.

**ETIOLOGY AND PATHOPHYSIOLOGY**

• CHL: Hearing loss can result from middle ear effusion, obstruction of canal (cerumen/foreign body, osteomas/exostoses, cholesteatoma, tumor), loss of continuity (ossicular discontinuity), stiffening of the components (myringosclerosis, tympanosclerosis, and otosclerosis), and loss of the pressure differential across the tympanic membrane (TM) (perforation).

• SNHL: damage along the pathway from oval window, cochlea, auditory nerve, and brainstem. Examples include vascular/metabolic insult, mass effect, infection and inflammation, and acoustic trauma.
  – Noise-induced hearing loss is caused by acoustic insult that affects outer hair cells in the organ of Corti, causing them to be less stiff. Over time, severe damage occurs with fusion and loss of stereocilia; eventually may progress to inner hair cells and auditory nerve as well.

• Large vestibular aqueduct or superior canal dehiscence: Third mobile window shunts acoustic energy away from cochlea.

**Genetics**

• Connexin 26 (13q11–13q12): most common cause of nonsyndromic genetic hearing loss

• Mitochondrial disorders (may predispose to aminoglycoside ototoxicity)

• Otosclerosis: familial

• Most common congenital syndromes
  – Alport syndrome
  – Stickler syndrome
  – Congenital cytomegalovirus
  – Usher syndrome
  – Branchio-oto-renal syndrome
  – Pendred syndrome
  – CHARGE association
  – Neurofibromatosis type 2
  – Waardenburg syndrome

**RISK FACTORS**

• Conductive
  – Eustachian tube dysfunction
    o Chronic sinusitis; allergy
    o Adenoid hypertrophy; nasopharyngeal mass
    o Cigarette smoking
  – Sleep apnea with continuous positive airway pressure (CPAP) use
  – Neuromuscular disease
  – Family history/heredity
  – Prematurity and low birth weight
  – Craniofacial abnormalities (e.g., cleft palate, Down syndrome)
  – Third mobile window (superior canal dehiscence or large vestibular aqueduct)

• Sensorineural
  – Aging/older age
  – Loud noise/acoustic trauma
Medications (aminoglycosides, loop diuretics, aspirin, nonsteroidal anti-inflammatory drugs (NSAIDs), quinine, chemotherapeutic agents, especially cisplatin, vancomycin)
- Tobacco, alcohol use
- Dizziness/vertigo: especially Ménière disease or history of labyrinthitis
- Bacterial meningitis
- Head trauma
- Atherosclerosis
- Vestibular schwannoma/skull base neoplasm
- Previous ear surgery

Sensorineural, pediatric specific
- Perinatal asphyxia
- Mechanical ventilation lasting ≥5 days
- Congenital infections (toxoplasmosis, other agents, rubella, cytomegalovirus, herpes simplex [TORCH] syndrome)
- Toxemia of pregnancy
- Maternal diabetes
- Rh incompatibility
- Prematurity or birth weight <1,500 g
- Severe hyperbilirubinemia; exchange transfusions
- Anomalous temporal bone (Mondini or large vestibular aqueduct)
- Infectious diseases (chickenpox, measles, encephalitis, influenza, mumps, bacterial meningitis)
- Vasculitis (Kawasaki disease)

GENERAL PREVENTION
- Limit noise exposure; use hearing protection.
- Avoid ear canal instrumentation (e.g., cotton swabs).
- Avoid or limit ototoxic medications.

COMMONLY ASSOCIATED CONDITIONS
Tinnitus: common for patients to experience both tinnitus and hearing loss.

DIAGNOSIS

HISTORY
- The U.S. Preventive Services Task Force concludes that the current evidence is insufficient to assess the balance of benefits and harms of screening for hearing loss in asymptomatic adults aged 50 years or older.
- Social problems and comments from friends and family members are often the first presentation of presbycusis (age-related hearing loss); patients are often not aware of the degree of hearing loss they experience and how it affects their life; insidious onset and progression.
- Difficulty hearing
  - Rapid versus gradual decline: Rapid loss (<3 days) is a medical emergency. Urgent ear/nose/throat referral and steroid therapy are recommended.
  - Difficulty with discrimination of sounds, hearing in crowds, or turning up the volume of
television sets.
– Frequently having to ask speakers to repeat.
– Friends/family complain of hearing loss.

- Tinnitus, bilateral or unilateral
- Otalgia
- Otorrhea, clear or purulent
- Dizziness or vertigo
- Aural fullness
- Autophony (hearing own voice louder or echoing)
- History of ear infections or ear surgeries
- History of trauma or noise exposure
- Family history of hearing loss
- History of recent viral infection

**PHYSICAL EXAM**

- Whispered voice test: A whisper heard from ~2 feet away is a good screen for intact hearing. Patients with SNHL have difficulty with this because their hearing loss is usually in the high frequency range.
- A simple 512-Hz tuning fork test lateralizes to unaffected ear in sudden SNHL (emergency) and lateralizes to the affected ear in CHL (not an emergency).
- 512-Hz tuning fork tests:
  - Sensorineural loss
    - Placed on the forehead: lateralizes to unaffected ear (Weber test)
    - Base of tuning fork placed on the mastoid and then fork end placed next to ear; heard louder next to ear—Air > Bone (+Rinne test).
  - Conductive loss
    - Placed on the forehead or teeth lateralizes to affected or symptomatic ear.
    - Placed on the mastoid and then next to ear; heard louder behind the ear on the side of conductive deficit—Bone > Air (− Rinne test).
- Otoscopy: Assess for deformity, canal patency, and otorrhea; TM integrity/retraction/mobility with insufflation, canal, or middle ear mass.
- Facial symmetry
- Cranial nerve exam
- Nasopharyngoscopy: adenoid hypertrophy or nasopharyngeal mass (mandatory in adult patient with new unilateral serous effusion)
- Pediatric: Survey for syndromic anomalies.

**DIFFERENTIAL DIAGNOSIS**

- Conductive
  - Cerumen impaction/foreign body
  - Perforation of TM
  - Middle ear fluid (serous otitis media)
  - Acute otitis media/adhesive otitis media
  - Ossicular erosion (infection, cholesteatoma)
  - Myringosclerosis/tymanosclerosis
  - Temporal bone fracture
  - Otosclerosis
- Glomus tumor
- Sensorineural
  - Presbycusis (age-related hearing loss)
  - Noise induced (recreational, occupational)
  - Ménière disease
  - Ototoxicity (aspirin, NSAIDs, aminoglycosides)
  - Viral labyrinthitis
  - Cerebellopontine angle (CPA) tumor
  - Large vestibular aqueduct syndrome
  - Syndromic hearing loss
  - Congenital cochlear malformation
  - Syphilis
  - Cytomegalovirus; rubella
  - Temporal bone fracture
  - Metabolic (hyper-/hypothyroidism)
  - Paget disease
  - Perilymphatic (inner ear) fistula
  - Vasculitis (including giant cell arteritis, Takayasu arteritis, polyarteritis nodosa, granulomatous with polyangiitis, microscopic polyangiitis, eosinophilic granulomatosis with polyangiitis, systemic lupus erythematosus, immune-complex associated vasculitis, and others) (2)
- Mixed
  - Acoustic neuroma

**DIAGNOSTIC TESTS & INTERPRETATION**

Consider as clinically indicated:
- Magnetic resonance imaging of the brain and brainstem with gadolinium to evaluate SNHL in congenital, early onset, and asymmetric hearing loss
- Fine-cut CT temporal bones without contrast may help in the evaluation of CHL
- Newborn screening with OAE and/or ABR
- Any pediatric patient with SNHL: Consider genetic testing for connexin 26, mitochondrial studies
- TORCH screening (congenital infection)
- Rapid plasma reagin (RPR) or venereal disease research laboratory (VDRL) confirmed by fluorescent treponemal antibody absorption (FTA-ABS)
- Lyme titer in endemic areas
- Antinuclear antibodies and sedimentation rate as a screen for autoimmune disease
- Pendred syndrome (goiter, mental retardation + SNHL): perchlorate test, thyroid function tests
- Alport syndrome (nephritis + SNHL): urinalysis, renal function tests
- Jervell and Lange-Nielsen syndrome (syncope, family history of sudden death + profound SNHL): ECG

**Diagnostic Procedures/Other**
- Audiometry: pure tone (air and bone), speech testing, and impedance (middle ear pressure) testing
- Tympanometry: Type B or C tympanograms indicate fluid or retraction, respectively. Negative middle ear peak pressures were seen even with normal (type A) tympanograms.
Other tests:
- ABR
- OAEs: “echo” of the cochlea
- Behavioral (visual reinforcement) audiometry; used in children 6 months to 5 years old.

Myringotomy and tubes can be considered for persistent fluid with hearing loss.

Test Interpretation
Varies depending on etiology

TREATMENT

MEDICATION
- Depends on cause
- Clinical practical guidelines for sudden hearing loss include the following:
  - Distinguishing SNHL from CHL; testing for bilateral sudden hearing loss in patients with unilateral sudden hearing loss; obtaining an MRI, ABR, or audiometric follow-up to evaluate for retrocochlear pathology; offer intratympanic steroid perfusion for refractory cases after initial management fails to treat idiopathic sudden SNHL (ISSNHL) and follow-up within 6 months of diagnosis.
  - May offer corticosteroids as initial therapy to patients with ISSNHL and hyperbaric oxygen therapy (HBOT) within 2 weeks of onset. May consider HBOT within 1 month of onset as salvage therapy.
  - Recommend against prescribing antivirals, thrombolytics, vasodilators, vasoactive substances, or antioxidants to patients with ISSNHL.
  - Recommend against routine laboratory tests in patients with ISSNHL.
- Treatment should begin ASAP, ideally within 1 to 2 weeks of onset with high-dose oral steroids: 1 mg/kg or 60 to 100 mg/day prednisone or 12 to 16 mg/day dexamethasone for 7 to 14 days, followed by a taper.
- Intratympanic steroids show similar efficacy to oral steroids and reduce systemic side effects.
- Newer studies are suggesting benefit of combined therapy (oral systemic steroid and intratympanic steroid injections) for first-line treatment of sudden SNHL.

ISSUES FOR REFERRAL
- Required for failure of newborn screen, but 32% lost to follow-up
  - Collaborating with Women, Infants, and Children (WIC) program to provide targeted follow-up improved loss to follow-up rates, decreased age at hearing confirmation by 1 month, and addressed reported care barriers (3).
- Audiology: If hearing loss is suspected, refer to audiology for formal evaluation
  - Audiologists may also provide hearing aid options and maintenance as indicated
- Genetics: if congenital syndrome or familial hearing loss is suspected
- Speech therapist: if speech delay or speech impediment is present
- Endocrinology: Pendred syndrome, other associated endocrine disorder (hypothyroidism)
- Cardiology: Jervell and Lange-Nielsen syndrome
- Ophthalmology: Usher syndrome
- Neurology and neurosurgery: CPA lesion, intracranial complication of middle ear disease
ADDITIONAL THERAPIES
Aural rehabilitation: interdisciplinary approach involving audiologists, speech language pathologists, otologist, family physician, and other members of health care team as needed.

SURGERY/OTHER PROCEDURES
- Surgical options for CHL:
  - Tympanostomy and tube placement
  - Tympanoplasty
  - Mastoidectomy
  - Ossicular chain reconstruction
  - Stapedectomy/stapedotomy
  - Canaloplasty
- Surgical options for SNHL
  - Cochlear implantation (in those with profound, bilateral hearing loss)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Audiogram and clinical exam are the primary means of monitoring patient. Patients with hearing assistive devices benefit from audiology involvement.

DIET
- Salt restriction to 2 g/day is helpful for patients with Ménière disease.
- Avoid or reduce alcohol consumption.

PATIENT EDUCATION
- To prevent damage that leads to noise-induced hearing loss, practice noise exposure moderation.
  - Avoid excessive noise.
  - Avoid prolonged noise exposure.
  - Use protective devices.
- National Institute on Deafness and Other Communication Disorders (NIDCD):

PROGNOSIS
- SNHL is usually permanent and may be progressive. However, amplification devices (e.g., hearing aids) may help improve functionality.
- ISSNHL may recover spontaneously in 32–70% of cases, but urgent referral and treatment is recommended to maximize recovery. No factors have been proven to predict recovery.

COMPLICATIONS
Acute middle ear problems may become chronic (perforations, cholesteatoma).

REFERENCES

**CODES**

**ICD10**
- H91.90 Unspecified hearing loss, unspecified ear
- H90.2 Conductive hearing loss, unspecified
- H90.5 Unspecified sensorineural hearing loss

**CLINICAL PEARLS**
- In sudden hearing loss, if a 512-Hz tuning fork test (Weber test) lateralizes to the unaffected ear, suspect sensorineural causes (emergent evaluation needed), but if it lateralizes to the affected ear, the diagnosis is CHL (not an emergency).
- ~80% of people aged >85 years have hearing loss; encourage screening and treatment, especially in patients with early dementia.
- Best way to prevent noise-induced hearing loss is to protect against noise exposure.
- Consider auditory rehabilitation in all patients.
HEART FAILURE, ACUTELY DECOMPENSATED
Muhammad Durrani, DO, MS ☞ Eric P. Blazar, MD ☞ Kevin Kucharski, DO

BASICS

DESCRIPTION
Acute decompensated heart failure (ADHF) is a rapid-onset impairment of cardiac pump function, either structurally or functionally, resulting in inefficient perfusion. This leads to a wide variety of symptoms that are secondary to excessive fluid accumulation and reduction in cardiac output. ADHF can be a new diagnosis or worsening of preexisting chronic heart failure (HF).

EPIDEMIOLOGY

Incidence
- HF is a growing healthcare concern with regard to morbidity and mortality. HF hospitalization places a major strain on health care resources, and Medicare spends more to diagnose and treat HF than any other medical condition. HF is the most common cause of admission and readmission in the United States in those over the age of 65, responsible for more than 1 million annual hospitalizations. In 2012, the total cost of HF was $30.7 billion. By 2030, the total cost will increase 127% to $69.7 billion. The majority of costs (approximately two-thirds) are attributed to the management of ADHF episodes. In the United States, there are 915,000 new cases annually. HF is the primary cause of >55,000 deaths each year and a contributing factor in >280,000 deaths.
- >1 million hospital discharges per year, unchanged from 2000 to 2010, and about half of people who have HF die within 5 years of diagnosis. One in nine deaths has HF mentioned on the death certificate.
- The average 1-year mortality rates for first hospitalized ADHF patients range from 20%–30%.

Prevalence
- ~6.5 million people age >20 years in the United States carry an HF diagnosis; prevalence is expected to increase 46% from 2012 to 2030, resulting in >8.4 million cases in patients >18 years of age.
- HF is primarily a disease of the elderly; 75% of hospital admissions for HF are in persons >65 years of age.
- African Americans have the highest risk of developing HF, followed by Hispanics, whites, and Chinese Americans, which reflects differences in the prevalence of hypertension (HTN), diabetes mellitus, atrial fibrillation, obesity, and socioeconomic status.

ETIOLOGY AND PATHOPHYSIOLOGY
- Two potential pathophysiologic conditions lead to the clinical findings of HF, namely systolic and/or diastolic heart dysfunction.
  - Systolic dysfunction: an inotropic abnormality, due to myocardial infarction (MI) or dilated or ischemic cardiomyopathy (CM), resulting in diminished systolic emptying (ejection fraction <45%)
  - Diastolic dysfunction: a compliance abnormality, due to hypertensive CM, in which
ventricular relaxation is impaired (ejection fraction >45%), resulting in decreased filling.

- In an attempt to adopt a more pragmatic classification system, one that has been accepted by both the European and American HF guidelines, the terms HF with reduced, midrange, or preserved LVEF (HFrEF, HFmrEF, and HFpEF, respectively) have been adopted recently.

- ADHF can result from the following conditions:
  - Myocardial disease:
    - Exacerbation of preexisting chronic HF heralded by noncompliance or infection
    - Any of the following as causes of new HF or exacerbation of preexisting chronic HF: coronary artery disease (CAD), MI, toxic damage, immune-mediated and inflammatory damage, infiltrative diseases, metabolic derangements, and genetic abnormalities
  - Abnormal loading conditions:
    - HTN, valvular and myocardial structural defects, pericardial and endomyocardial pathologies, high-output states, volume overload
  - Arrhythmias:
    - Atrial fibrillation, tachyarrhythmias, high-grade heart block, bradyarrhythmias

**Genetics**
Familial CM is a predisposition to the development of HF (rare).

**RISK FACTORS**
- CAD and MI: RR 8.1
- Diabetes mellitus: RR 1.9
- Cigarette smoking: RR 1.6
- Valvular heart disease: RR 1.5
- HTN, systemic or pulmonary: RR 1.4
- Dietary sodium intake: RR 1.4
- Obesity: RR 1.3

**GENERAL PREVENTION**
Mortality reduction has been attributed to treating HF risk factors (see above), with the implementation of ACE inhibitors, β-blockers, coronary revascularization, implantable cardioverter-defibrillators, and cardiac resynchronization strategies in patients.

- Some recommend B-type natriuretic peptide (BNP) screening in conjunction with guideline-directed management/therapies for at-risk populations to aid in the prevention of new-onset HF and to delay development of left ventricular (LV) dysfunction in existing HF.

**COMMONLY ASSOCIATED CONDITIONS**
- Dysrhythmia followed by pump failure is the leading cause of death in ADHF. Most patients have >5 comorbidities (especially CAD, chronic kidney disease, and diabetes) and take >5 medications.
- Cardiogenic shock

**DIAGNOSIS**
Requires a multifaceted clinical approach with no gold standard diagnostic test: No single historical, physical exam (PE), ECG, or radiographic finding can rule out HF.

**HISTORY**
Patients typically have a history of HF, MI, uncontrolled HTN, and other risk factors mentioned above.

Dyspnea on exertion and orthopnea are the only symptoms with high sensitivity but suffer from low specificity.

Other symptoms include diminished exercise capacity, fatigue, general weakness, chest pain/discomfort if acute coronary syndrome (ACS) is present, paroxysmal nocturnal dyspnea, nocturnal nonproductive cough, wheezing (especially nocturnal) in absence of a history of asthma or infection (cardiac asthma).

Edema, abdominal bloating (ascites), anasarca, cyanosis, weight gain (>2 kg/week).

PHYSICAL EXAM
- \( S_3 \) has the highest likelihood ratio (LR) in respect to PE with positive LR ranging from 1.6 to 13.0. No PE finding has sensitivity >70%.
- Peripheral pitting edema, cool extremities, cyanosis, hepatomegaly, hepatojugular reflux, cardiac murmur, hypotension, laterally displaced apical impulse
- Lung exam: rales (crackles) and sometimes wheezing, Cheyne-Stokes respirations

DIFFERENTIAL DIAGNOSIS
Rule out life-threatening diagnoses first: pulmonary embolism, MI, tamponade, pneumothorax, acute respiratory distress syndrome, sepsis, chronic obstructive pulmonary disease (COPD), pneumonia, constrictive pericarditis, high-output states (anemia, hyperthyroidism).

DIAGNOSTIC TESTS & INTERPRETATION
Laboratory data are adjunctive and help with prognostication and clinical course.

Initial Tests (lab, imaging)
- First, assess blood pressure (BP) and other vital signs and rule out hemodynamic instability and signs of cardiogenic shock.
- ECG and cardiac troponins to evaluate for acute coronary syndrome (ACS). Note that elevated troponins are detected in the majority of HF patients, often without obvious myocardial ischemia.
- BUN, creatinine, electrolytes, liver function tests, TSH (new-onset), glucose, and CBC
- Routine ABG is not indicated.
- Transthoracic echocardiogram: recommended immediately in hemodynamically unstable ADHF patients and within 48 hours when cardiac structure and function are either not known or may have changed since previous studies.
- BNP and/or N-terminal fragment pro-BNP (NT-proBNP): Measurement of BNP or NT-proBNP is recommended in all patients with acute dyspnea and suspected ADHF to help in the differentiation of ADHF from noncardiac causes.
  - BNP <100 essentially will rule out HF with negative LR of 0.2 and sensitivity of 93.5%.
  - BNP >500 have a specificity of 89.8%. BNP 100 to 400 may indicate HF or may be due to a variety of cardiac and noncardiac conditions.
  - BNP has a relative increase in women, is lower with obesity, and is higher with renal dysfunction.
- NT-proBNP values >450 pg/mL for people age <50 years, >900 pg/mL ages 50 to 75 years, and >1,800 pg/mL ages >75 years are highly suggestive of HF (sensitivity 90%, specificity of 84%) in the correct clinical setting (1)[B].
- Chest x-ray: to assess for pulmonary congestion and to detect other cardiac or noncardiac
diseases that may cause or contribute to the patient’s symptoms: cardiomegaly, vascular redistribution (cephalization) with “butterfly” pattern of pulmonary edema, interstitial and alveolar edema, Kerley B lines, pleural effusions

- Lung ultrasound (LUS): emerging as a diagnostic tool for ADHF with a positive LUS defined by the presence of >3 B lines in two bilateral lung zones yielding a specificity of 92.7% and LR of 7.4

Follow-Up Tests & Special Considerations
Please see “Heart Failure, Chronic.”

Diagnostic Procedures/Other
Cardiac catheterization may be considered when CAD is suspected. Pulmonary artery catheterization may be performed to guide therapy in severe cases with cardiogenic shock.

Test Interpretation
Cardiac pathology depends on the etiology of HF. Please refer to “Heart Failure, Chronic.”

TREATMENT
The goal of treatment is to improve hemodynamics and organ perfusion, alleviate symptoms, limit cardiac and renal damage, restore oxygenation, and minimize hospital length of stay as well as identify the etiology or precipitating factors. See “Heart Failure, Chronic” as well.

MEDICATION

ALERT
Contemporary therapies for ADHF remain suboptimal, and many therapies do not favorably impact morbidity or mortality. Diuretics are used initially in fluid overload ADHF, with nitrates added as needed. Once ADHF is stabilized, the guideline suggests an ACE inhibitor, ARB, or ARNI and β-blocker be started in patients with reduced systolic function. Use of new agent ivabradine has also been touted in select patients but has not been shown to reduce cardiovascular mortality. Avoid NSAIDs and COX-2 inhibitors. There are no class IA drug recommendations for ADHF.

First Line
- Vasodilators: Consider in ADHF with systolic blood pressure [SBP] >90 mm Hg, and patients with hypertensive ADHF should get IV vasodilators as initial therapy to reduce congestion. Use in chronic HF is not effective (1)[B]. Vasodilators lower ventricular filling pressure and systemic vascular resistance to indirectly improve cardiac function.
  - IV nitroglycerin may be of short-term benefit by decreasing preload and afterload by dilating peripheral capacitance and resistance vessels on vascular smooth musculature (IV 10 to 20 μg/min, increase up to 200 μg/min).
  - IV nitroprusside: Administer with caution, start with 0.3 μg/kg/min, and increase up to 5.0 μg/kg/min.
- IV loop diuretics recommended for all patients with ADHF and symptoms of fluid overload in hemodynamically stable patients (contraindicated if SBP <90 mm Hg, severe hyponatremia, acidosis); be cautious of electrolyte abnormalities if kidney disease is present. Diuresis should be instituted early in ADHF, continuous infusion is no better than bolus, and high dose is not
significantly better than low dose.
- Furosemide (Lasix): New-onset ADHF patients should get boluses of 20 to 40 mg IV.
- If on furosemide (Lasix) chronically, initial IV dose should be equal or exceed chronic oral daily dose (1.0–2.5 times home dose). Monitor for appropriate urine output.
- Thiazides in combination with loop diuretics may be useful if ineffective diuresis (hydrochlorothiazide [HCTZ] 25 mg PO). Thiazides and spironolactone or eplerenone (25 to 50 mg PO) may be used in combination with loop diuretics if excessive volume overload.
- Metolazone (Zaroxolyn): 2.5 to 20.0 mg/day PO can be added as the second diuretic in cases of ineffective diuresis and may be more effective than other thiazides in patients with renal insufficiency.
- Bilevel positive airway pressure (BIPAP)/NPPV: NPPV decreases early mortality in ADHF. See “Additional Therapies” section.

**Second Line**
- Tolvaptan (an oral vasopressin antagonist) for severe hypovolemic hyponatremia refractory to water restriction and medical therapy
- Inotropes: reserved for patients with severe systolic dysfunction occurring most often in hypotensive ADHF. Withdraw as hemodynamics improve due to increased short- and medium-term mortality. ECG monitoring is required because they can induce ischemia and arrhythmias.
  - Phosphodiesterase inhibitors (milrinone, enoximone) decrease pulmonary resistance; may be used for patients on β-blockers but may increase medium-term mortality in CAD patients. Milrinone specifically produces ionotropic and vasodilatory effects without beta-adrenergic stimulation of the heart.
  - Dobutamine infusion 2 to 20 μg/kg/min requires close BP monitoring; avoid in cardiogenic shock or with tachyarrhythmias. Dobutamine works through a positive ionotropic effect along with stimulation of beta-adrenergic receptors in the heart.
  - Low-dose dopamine infusion may be considered (3 to 5 μg/kg/min).
  - Levosimendan (calcium sensitizer) improves hemodynamic parameters but not survival compared to placebo while improving hemodynamic parameters and survival compared to dobutamine.
- Vasopressors: Consider in patients with cardiogenic shock despite treatment with another inotrope.
  - Norepinephrine 0.2 to 1.0 μg/kg/min compared with dopamine (0.5 to 2.5 μg/kg/min) has fewer side effects and lower mortality.
  - Epinephrine restricted to patients with persistent hypotension despite other agents
- Nesiritide, a BNP analog, is not recommended secondary to higher rates of hypotension, no benefit on death, or rehospitalization rates.
- Ultrafiltration renal replacement therapy: Routine use of ultrafiltration is not recommended and should be used only in patients with refractory volume overload.
- Extracorporeal Membrane Oxygenation (ECMO): Veno-arterial ECMO for the sickest cohort of ADHF patients. ECMO has been used as a bridge to transplant or to long-term mechanical support.

**ADDITIONAL THERAPIES**
- Oxygen: Begin treatment early; ideally titrate to an arterial oxygen saturation >92% (90% if COPD).
Cochrane review shows that one death can be avoided for every 14 ADHF patients treated with NPPV and one death for every 9 ADHF patients treated with CPAP. Avoid mechanical ventilation for patients with right HF if possible.

Treat anemia with transfusion: conservative trigger Hgb <8; target Hgb 10. IV iron replacement may help with New York Heart Association (NYHA) II and III patients. Avoid erythropoietin-stimulating agents.

For patients with new-onset arrhythmias, consider pacing and/or antiarrhythmics.

Please refer to “Heart Failure, Chronic” for maintenance treatments.

SURGERY/OTHER PROCEDURES

Heart valve surgery if valvular disease is responsible.

PCI/CABG for patients with CAD/MI if applicable.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Admission criteria considerations:

– Evidence of severely decompensated HF, including hypotension, worsening renal function, altered mental status, dyspnea at rest, decreased oxygenation, arrhythmias, electrolyte disturbances, associated comorbid conditions, as well as newly diagnosed HF.

– Consider observation unit stay for stable patients with preexisting HF and the following:
  
  o No acute interventions needed for comorbid condition, SBP >120 mm Hg, RR <32 bpm, BUN <40 mg/dL, creatinine <3.0 mg/dL, no evidence of ischemia or elevated troponins, and BNP <1,000, N-type pro-BNP <5,000.
  
  o The clinical impression that the patient could be discharged in the next 24 hours

Inpatient: continuous pulse oxygen; daily weights; monitor input and output; fluid restriction; 2-g sodium diet; echocardiogram if necessary; monitor for worsening HF; assess treatment response.

1.5 to 2.0 L/day fluid restriction may be useful to reduce congestive symptoms.

Discharge criteria: improved symptoms, SBP normalized at 100 to 120 mm Hg, good urine output, serum sodium >135 mEq/L, HF outpatient education.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Rapid follow-up and multidisciplinary care to reduce hospitalization and mortality.

DIET

Reduce sodium (2 g); maintain cardiac or diabetic diet if these comorbidities are present.

PATIENT EDUCATION

– Monitoring and self-care; record daily weight; know how/when to use health care systems to increase the diuretic dose with weight gain or dyspnea.

– Medications: Understand indications, dose, effects, and side effects of drugs.

– Adherence: Value treatment plan maintenance.

– Alcohol, smoking, and drugs: abstinence recommended in alcohol-induced CM; smoking and illicit drug cessation
Exercise: Understand the benefits of exercise.

PROGNOSIS
- The ADHERE risk tree stratifies ADHF patients for inpatient mortality using SBP, BUN, and creatinine.
- S_3 on PE correlates with poor prognosis.
- After diagnosis, 1-year survival ~75%, 5-year survival <50%, 10-year survival <25%.
- Consider predischarge BNP to establish postdischarge prognosis in hospitalized patients (1) [C].

COMPLICATIONS
Arrhythmia, pulmonary edema, hyponatremia, death

REFERENCES

CODES
ICD10
- I50.9 Heart failure, unspecified
- I50.21 Acute systolic (congestive) heart failure
- I50.31 Acute diastolic (congestive) heart failure

CLINICAL PEARLS
- BNP in ADHF is helpful in situations in which the diagnosis of ADHF is unclear.
- Look for an underlying cause of each episode of ADHF.
- IV nitrates (especially if patient is hypertensive) and IV diuretics are used initially in fluid-overload acute HF.
- Using early noninvasive ventilation for the treatment of pulmonary edema can bridge care while awaiting the effects of diuretics and can decrease morbidity and mortality associated with intubation.
HEART FAILURE, CHRONIC
Jeffrey A. Shih, MD • Youssef Rahban, MD

BASICS

DESCRIPTION
• Heart failure (HF) is the condition resulting from inability of the heart to fill and/or pump blood sufficiently to meet tissue metabolic needs. Alternatively, HF may occur when adequate cardiac output can be achieved only at the expense of elevated filling pressures. It is the principal complication of heart disease. For acute HF, see “Heart Failure, Acutely Decompensated.”
• HF is the preferred term over congestive HF because patients are not always congested (fluid overloaded).
• HF may involve the left heart, the right heart, or be biventricular.
• The New York Heart Association (NYHA) classification is a subjective grading scale used for classifying a patient’s functional status: NYHA I: asymptomatic; NYHA II: symptomatic with moderate exertion; NYHA III: symptomatic with mild exertion and may limit activities of daily living; NYHA IV: symptomatic at rest.
• The American Heart Association (AHA) and American College of Cardiology (ACC) stages is a system to delineate the progression of HF: Stage A: patients at risk for HF, no structural disease; Stage B: structural disease, no HF symptoms; Stage C: structural disease, HF symptoms; Stage D: end-stage HF disease.

EPIDEMIOLOGY
HF accounts for close to 1 million hospitalizations a year with 25% readmitted within 30 days. The annual direct and indirect cost of HF in the United States is ~$34.4 billion.

Incidence
In the United States, 550,000 new cases diagnosed annually with >250,000 deaths per year.

Prevalence
• An estimated 23 million individuals have HF worldwide. ~6.5 million people in the United States have HF; <1% in those age <50 years, increasing to 10% of those age >80 years
• Primarily a disease of the elderly; 75% of hospital admissions for HF are for persons >65 years of age.

ETIOLOGY AND PATHOPHYSIOLOGY
Two physiologic components explain most of the clinical findings of HF and result in classifications in four general categories:
• HF with reduced ejection fraction (HFrEF) or systolic HF: an inotropic abnormality, often due to myocardial infarction (MI) or dilated cardiomyopathy (CM), resulting in diminished systolic emptying (ejection fraction [EF] ≤40%)
• HF with preserved ejection fraction (HFpEF) or diastolic HF: a compliance abnormality, often due to hypertensive CM, in which the ventricular relaxation is impaired (EF ≥50%)
• Borderline HFpEF (EF 41–49%): mild systolic dysfunction but clinically behaves like HFpEF
• Improved HFpEF (EF >40%): previously HFrEF but with improvement in systolic function
Patients with systolic dysfunction may also have diastolic dysfunction.

Most common etiologies: coronary artery disease (CAD)/MI and hypertension (HTN)

Myocarditis and CM: alcoholic, viral, long-standing HTN, drugs (e.g., chemotherapeutic agents), muscular dystrophy, infiltrative (e.g., amyloidosis, sarcoidosis), postpartum state, infectious (e.g., Chagas disease, HIV), hypertrophic CM (HCM), inherited familial dilated CM, left ventricular (LV) noncompaction

Valvular and vascular abnormalities: any valvular stenosis or regurgitation, rheumatic heart; renal artery stenosis, usually bilateral, may cause recurrent “flash” pulmonary edema, especially in setting of severe chronic HTN.

Chronic lung disease and pulmonary HTN (cor pulmonale)

Iatrogenic volume overload (requires extreme overload in patients with normal hearts and kidneys)

Arrhythmias (atrial fibrillation and other tachyarrhythmias, high-grade heart block, frequent PVCs)

Miscellaneous: high-output states: hyperthyroidism, anemia; cardiac depressants (β-blocker overdose), stress induced

Idiopathic: 20–50% of idiopathic dilated cardiomyopathies are familial.

HF is progressive—manifested by the remodeling (altered heart geometry) process.

Genetics

Multiple genetic abnormalities responsible for a variety of phenotypes have been identified (HCM, arrhythmogenic right ventricular [RV] dysplasia, LV noncompaction, dilated CM).

Consider genetic screening for first-degree relatives of HCM and arrhythmogenic RV dysplasia.

RISK FACTORS

For development of HF: CAD/MI, HTN (80% of cases of HF in the United States caused by either CAD or HTN), valvular heart disease, diabetes mellitus, cardiotoxic medications (e.g., anthracyclines, tyrosine-kinase inhibitors, tumor necrosis factor-α inhibitors), obesity, older age

GENERAL PREVENTION

Control HTN and other risk factors. Thiazide diuretics and angiotensin-converting enzyme inhibitors (ACE-I) are superior to other agents in preventing development of HF.

COMMONLY ASSOCIATED CONDITIONS

Sudden cardiac death and progressive pump failure are the leading causes of death. Most patients have >5 comorbid medical conditions and take >5 medications.

DIAGNOSIS

HISTORY

Dyspnea on exertion: cardinal sign of left-sided HF. Deteriorating exercise capacity: easy fatigued, general weakness

Nocturnal nonproductive cough, orthopnea, and paroxysmal nocturnal dyspnea; sometimes frothy or pink sputum. Wheezing, especially nocturnal, in absence of history of asthma or infection (cardiac asthma); Cheyne-Stokes respirations

Anorexia and/or fullness or dull pain in right upper quadrant (hepatic congestion). Nausea and poor appetite may indicate advanced HF.
PHYSICAL EXAM
- Increased filling pressures: rales and sometimes wheezing, peripheral edema, S3 gallop, hepatomegaly, jugular venous distention, hepatojugular reflux, ascites
- Remodeling: enlarged or displaced point of maximal impulse
- Poor cardiac output: hypotension, pulsus alternans, tachycardia, narrow pulse pressure, cool extremities, cyanosis

DIFFERENTIAL DIAGNOSIS
Simple dependent edema, pulmonary embolism, exertional asthma, cardiac ischemia, asthma/chronic obstructive pulmonary disease, constrictive pericarditis, nephrotic syndrome, cirrhosis, venous occlusive disease with subsequent peripheral edema, high-output states: anemia, sepsis, hyperthyroidism, lymphedema, tamponade

DIAGNOSTIC TESTS & INTERPRETATION
Diagnosis should be primarily clinical, with laboratory data as adjunctive and indicative of complications.

Initial Tests (lab, imaging)
- β-Type natriuretic peptide (BNP) and N-terminal pro-BNP (NT-BNP) are helpful in the acute setting to differentiate the cause of dyspnea (BNP <100 essentially rules out HF). A BNP level in those with risk factors for developing HF or with structural heart disease but no symptoms of HF can help predict the development of symptomatic HF (1)[A]. Other, non-HF conditions, such as pulmonary embolism, renal failure, and acute coronary syndromes, may cause elevated BNP. Of note, sacubitril/valsartan (Entresto), an angiotensin receptor blocker and neprilysin inhibitor can raise BNP levels but has less impact on NT-proBNP levels. Obesity may lower BNP levels. The use of BNP-guided therapy in chronic HF and acutely decompensated HF is not well established, although a predischarge BNP can predict risk of readmission and survival (1)[A].
- Lab findings include respiratory alkalosis, mild azotemia, decreased erythrocyte sedimentation rate, proteinuria (usually <1 g/day), elevated creatinine (cardiorenal syndrome), dilutional hyponatremia (poor prognosis), hyperuricemia, and hyperbilirubinemia.
- Chest x-ray (changes lag clinical symptoms by up to 6 hours): increased heart size, vascular redistribution (cephalization) with “butterfly” pattern of pulmonary edema, interstitial and alveolar edema, Kerley B lines, and pleural effusions. Findings of pulmonary edema may be absent in long-standing HF.

Diagnostic Procedures/Other
Determination of left ventricular ejection fraction (LVEF) is critical to proper diagnosis and management:
- Echocardiogram is the most useful test to determine LVEF, RV function, diastolic dysfunction, ventricular size, wall thickness, and valvular abnormalities; may be repeated if change suspected in underlying cardiac status
- Nuclear imaging to estimate ventricular sizes; assess for ischemia or infarction, ATTR wild-type amyloidosis, and systolic function.
- Cardiac MRI can be considered in select circumstances: suspicion of cardiac sarcoidosis, arrhythmogenic RV CM, acute myocarditis, amyloidosis, and hemochromatosis.
- Cardiac catheterization is important for excluding CAD as an etiology in the setting of risk
Endomyocardial biopsy should not be performed routinely, only in special circumstances (e.g., suspected giant cell myocarditis) that may change therapy.

Test Interpretation
Cardiac pathology depends on underlying etiology.

TREATMENT

GENERAL MEASURES
Correct and treat risk factors for HF. The treatment of chronic HF is focused on improving hemodynamics, relieving symptoms, and blocking the neurohormonal response to improve survival.

MEDICATION
Diuretics (for fluid overload) and nitrates (especially for hypertensive patients) are used initially in acute HF management. The addition of ACE-I and aldosterone antagonists (especially for HFrEF) can be added at any time. Once acute HF is stabilized, a β-blocker should be started. Avoid nonsteroidal anti-inflammatory drugs (NSAIDs), which markedly worsen HF. Avoid the use of diltiazem and verapamil in patients with systolic dysfunction because they may increase mortality and have negative inotropic effects.

First Line
- ACE-I: used to decrease afterload. Shown to increase survival, improve symptoms, and overall exercise capacity in patients in all NYHA classifications; benefit greatest for patients with systolic dysfunction and post-MI. Number needed to treat (NNT) ~25 per year for mortality. All ACE-Is considered equally effective. Initiate at low doses and titrate as tolerated to target doses.
- Angiotensin receptor blockers (ARBs) are indicated for those who are intolerant to ACE-Is. Do not use combination of ACE-I and ARB.
- β-Blockers: used in systolic or diastolic HF (Note: Initiate in hemodynamically stable/compensated patients at low dose and titrate upward slowly.); NNT = 25/year for mortality. Mortality decreased in systolic HF; evidence for titration to heart rate (HR) rather than specific dose
  - Carvedilol: 3.125 mg PO BID to a target of 25 mg PO BID; metoprolol succinate extended release: 12.5 mg/day PO to a target of 200 mg/day PO; or bisoprolol: 1.25 to 10.00 mg once daily (currently not FDA-approved for the treatment of HF)
- Sacubitril/valsartan (Entresto) is an angiotensin receptor blocker and neprilysin inhibitor (ARNI) shown to reduce the risk of CV death and HF hospitalizations in patients with HFrEF. In patients with HFrEF and NYHA class II and III symptoms who tolerate an ACE-I or ARB, and CrCl >30, replacement by an ARNI is recommended to further reduce morbidity and mortality (NNT to prevent one CV death over 3.5 years: 31). ACE-Is should be discontinued at least 36 hours prior to starting ARNIs. The most common adverse effects include hypotension, angioedema, and renal insufficiency. Cost is >$500/month. Diuretics are helpful to manage volume overload/reduce preload.
  - Furosemide (Lasix): 20 to 320 mg/day IV/IM/PO divided dose; bumetanide (Bumex): 0.5 mg to 10.0 mg/day IV/PO divided dose; torsemide (Demadex): 10 to 200 mg/day PO
divided dose

- Metolazone (Zaroxolyn): 2.5 to 20.0 mg/day PO divided dose; hydrochlorothiazide: 12.5 to 100.0 mg/day PO divided dose; chlorothiazide (Diuril): 250 to 2,000 mg/day IV/PO divided dose
- Spironolactone, eplerenone (improve mortality when added to standard therapy in NYHA class II to IV + EF <35%): spironolactone 12.5 to 25.0 mg/day PO; maximum 50 mg/day PO; eplerenone 25 to 50 mg/day; caution regarding hyperkalemia and chronic kidney disease (CKD)

- Digoxin reduces symptoms but has not clearly shown any positive effect on mortality: In patients with preserved renal function (CrCl >50 mL/min), the recommended dose is 0.125 mg/day. Levels lower than used for atrial fibrillation are effective and safer.
- The combination of hydralazine (75 mg/day divided BID or TID) and isosorbide dinitrate (40 mg QID) is effective for improving survival and reducing hospitalizations in African Americans and can be used if the patient is unable to take an ACE-I or an ARB.
- Ivabradine (Corlanor) can be considered in patients with NYHA II and III HF, EF ≤35%, on maximally tolerated β-blockers with HRs >70 to reduce hospitalization from worsening HF. Ivabradine is contraindicated in ADHF, hypotension (<90/50 mm Hg), severe hepatic impairment, pacemaker dependence, bradyarrhythmias, or strong CYP3A4 inhibitors. It should not be administered to patients who are currently in atrial fibrillation and should be discontinued if atrial fibrillation develops.
- Intravenous iron replacement might improve functional status and quality of life in patients with NYHA II and III HF and iron deficiency (ferritin <100 ng/mL or 100 to 300 ng/mL if transferrin saturation <20%).
- In diastolic HF, no medical therapy has improved survival. ARBs and spironolactone can be used to potentially reduce hospitalizations.

**ADDITIONAL THERAPIES**

Device therapy including implantable cardioverter-defibrillators (ICDs) and cardiac resynchronization therapy (CRT) shown to improve outcomes.

- CRT is recommended for patients in sinus rhythm with a QRS width ≥150 ms due to left bundle branch block (LBBB) and LVEF ≤35% and persistent mild to moderate HF (NYHA II and III) despite optimal medical therapy. CRT may be considered for ambulatory NYHA class IV patients in sinus rhythm with a QRS width ≥150 ms, LBBB, and LVEF ≤35%.
- CRT may be considered for patients with LVEF ≤35%, sinus rhythm, QRS width ≥150 ms, non-LBBB pattern, and NYHA III or ambulatory NYHA IV symptoms.
- CRT may also be considered for patients with a QRS width between 120 and 150 ms, LBBB, LVEF ≤35%, and persistent mild to severe HF (NYHA II to IV) despite optimal medical therapy.
- ICDs are recommended for primary prevention in patients with nonischemic CM and ischemic CM who are at least 40 days post-MI; LVEF ≤35%, NYHA class II or III HF, or LVEF ≤30%, NYHA I HF; and on optimal medical therapy and >1 year estimated survival; generally not indicated in American Heart Association (AHA) stage D (end-stage) HF
- CRT is recommended in patients with reduced LVEF and chronic RV pacing or with bradyarrhythmias and an anticipated need for a pacemaker.
- Implantable hemodynamic monitoring with devices such as the pulmonary artery pressure sensor to reduce the risk of admission after an HF-related admission in the last 12 months in patients with an elevated BNP or NT-proBNP and NYHA functional class III.
In patients with HFrEF and secondary moderate to severe mitral regurgitation (MR), transcatheter edge-to-edge mitral leaflet repair device (MitraClip) may be used to reduce MR by improving the coaptation of the anterior and posterior mitral leaflets. The optimum patient selection has not been fully defined.

**SURGERY/OTHER PROCEDURES**
- Heart valve surgery if defective heart valve is responsible; mitral valve repair especially helpful if mitral regurgitation is the primary issue and not functional
- Advanced therapies such as cardiac transplantation and LV assist device (LVAD) implantation can be considered in patients with HF refractory to conventional medical/device therapies without other disqualifying medical and psychosocial conditions. Cardiac transplantation is generally considered for patients ≤70 years old with a predicted 1-year survival worse than that afforded by transplantation. Consideration can be made for patients >70 years with few comorbid conditions. Indications for LVAD implantation are generally similar to cardiac transplantation but are evolving.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- See “Heart Failure, Acutely Decompensated.”
- Admit patients with hemodynamic/respiratory compromise, hypoxia/hypoxemia, change in mental status, acute renal insufficiency, significant volume overload, and significant electrolyte abnormalities (e.g., hyponatremia).
- Discharge criteria: subjective improvement, euvoema on clinical assessment, resting HR <100 bpm, systolic BP >80 mm Hg, HF outpatient education performed

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Critical patient education performed at all outpatient and inpatient physician visits
- Rapid office follow-up (7 days) after hospitalization

**Patient Monitoring**
Home health monitoring by specially trained nurses have been shown to decrease frequency of hospitalizations. Readmissions remain problematic.

**DIET**
Reduce sodium load (<1.5 to 2.0 g/day). Optimal level is unknown.

**PATIENT EDUCATION**
AHA: [www.americanheart.org](http://www.americanheart.org)

**PROGNOSIS**
After diagnosis: 1-year survival ~75%, 5-year survival <50%, and 10-year survival <25%

**COMPLICATIONS**
Sudden death (arrhythmic), acute pulmonary edema, death, progressive pump failure

**REFERENCES**

Algorithm: Congestive Heart Failure: Differential Diagnosis

CODES

ICD10

- I50.9 Heart failure, unspecified
- I50.1 Left ventricular failure
- I50.22 Chronic systolic (congestive) heart failure

CLINICAL PEARLS

- Have patients weigh themselves daily and report weight gains of >2 lb in a day or 5 lb above dry weight.
- β-Blockers, ACE-I, and aldosterone antagonists are the core medications for management of chronic HF.
- Consider referral for biventricular pacing in patients with LBBB and ICD in those with low EF.
HEAT ILLNESS: HEAT EXHAUSTION AND HEAT STROKE
Sean C. Robinson, MD, CAQSM

BASICS

DESCRIPTION

- A continuum of increasingly severe illness caused by dehydration, electrolyte losses, and failure of thermoregulatory mechanisms when exposed to elevated environmental temperatures
  - Heat exhaustion is a mild to moderate form of heat illness displaying dehydration-type symptoms with a normal to elevated temperature <104°F (<40°C) (1).
  - Heat stroke is characterized by an elevated core temperature >104°F (>40°C) with central nervous system (CNS) abnormalities and is a true medical emergency (1,2).

- Can be exertional (related to activity) or nonexertional
- System(s) affected: endocrine/metabolic, nervous, hepatic, hematologic
- Synonym(s): heat illness; heat injury; hyperthermia; heat collapse; heat prostration

Geriatric Considerations
Elderly persons are more susceptible.

Pediatric Considerations
Children are more susceptible.

Pregnancy Considerations
Pregnant women may be more susceptible to volume depletion with heat stress.

EPIDEMIOLOGY

- Predominant age: more likely in children or elderly
- Predominant sex: male = female

Incidence

- Depends on intensity of heat; estimate of 20/100,000 persons per season
- Concern for increasing incidence because ambient environmental temperatures continue to rise

Prevalence

- Depends on predisposing conditions in combination with environmental factors
- Roughly 600 deaths per year in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

- Excess heat has direct cellular toxicity. Excess heat also leads to an imbalance between inflammatory and anti-inflammatory cytokines, vascular endothelial damage, and end-organ dysfunction.
- Interplay between failure of heat-dissipating mechanisms, an overwhelming heat stress, and an exaggerated acute-phase inflammatory response

RISK FACTORS

- Poor acclimatization to heat
- Poor physical conditioning
- Salt or water depletion
- Obesity
- Acute febrile or gastrointestinal illnesses
- Chronic illnesses: uncontrolled diabetes mellitus, hypertension, cardiac disease
- Alcohol and other substance abuse
- High heat and humidity, poor environmental air circulation
- Heavy, restrictive clothing
- Nutritional supplements (e.g., ephedra) (2)
- Medications (α-adrenergics, anticholinergics, antihistamines, antipsychotics, benzodiazepines, β-blockers, calcium channel blockers, clopidogrel, diuretics, laxatives, neuroleptics, phenothiazines, thyroid agonists, tricyclic antidepressants) (1)

GENERAL PREVENTION
- The most important factor in preventing heat illness is prevention. Activity modification and adequate fluid replacement are key preventive measures.
- Allow acclimatization through proper conditioning and activity modification.
- Dress appropriately with loose-fitting, open-weaved, light-colored clothing.
- Consume a proper volume of fluids, particularly during physical activity in hot environments.
- Never leave children (or pets) unattended in cars during hot weather.
- Try to gain access to air-conditioned environments during hot weather.

DIAGNOSIS
- Heat exhaustion: Symptoms are milder than in heat stroke, and there are no CNS derangements:
  - Fatigue, lethargy, weakness, dizziness, nausea, vomiting, myalgias, headache, profuse sweating, tachycardia, hypotension, thirst, hyperventilation
  - Core temperature usually elevated but can be normal; if elevated, usually <104°F (<40°C)
- Heat stroke: marked by mental status changes and elevated core temperature
  - Classic (nonexertional): caused by environmental exposure, primarily in elderly or chronically ill patients, and may develop gradually over days
    - Delirium
    - Confusion
    - Coma
    - Core temperature >104°F (>40°C)
    - Hot, flushed, dry skin
  - Exertional: typically younger, active patients; rapid onset
    - Exhaustion
    - Confusion, disorientation
    - Delirium
    - Coma
    - Hot, flushed skin, typically with sweating
    - Core temperature >104°F (>40°C) (1,2)

HISTORY
- Heat cramps: sweating; muscle cramps/spasms
• Heat exhaustion: sweating; fatigue, lightheadedness/dizziness; cramping; nausea, vomiting; headache
• Heat stroke: Altered mental status

**PHYSICAL EXAM**
• Rectal temperature (Don’t rely on oral temperature.)
• Heat exhaustion: tachycardia; cool/clammy skin;
• Heat stroke: Rectal (core temperature) elevated (>103°F [<39.5°C]); hot/dry skin (compensatory sweating impaired)

**DIFFERENTIAL DIAGNOSIS**
• Febrile illnesses, sepsis
• Drug-induced fluid loss
• Cardiac arrhythmia or infarction
• Acute cocaine intoxication
• Neuroleptic malignant syndrome
• Malignant hyperthermia (an autosomally inherited disorder of skeletal and cardiac muscle in which patients have abnormal muscle metabolism on exposure to halothane or skeletal muscle reactants)

**DIAGNOSTIC TESTS & INTERPRETATION**
Detect end-organ damage

**Initial Tests (lab, imaging)**
• Creatinine, blood urea nitrogen, electrolytes (sodium in particular)
• Liver enzymes, muscle enzymes (creatine phosphokinase)
• Complete blood count—hemoconcentration
• Urinalysis: increased urine specific gravity
• Drugs that may alter lab results: diuretics

**TREATMENT**

**GENERAL MEASURES**
• For heat stroke: immediate body immersion in ice water to cool core temperature. Monitor hemodynamics and airway status (1)[C].
• Careful fluid and electrolyte replacement with normal saline; avoid hypotonic fluids. Follow serum sodium (1),(2)[C].
• Consider central venous pressure (CVP) monitoring.
• For heat exhaustion, consider:
  – Evaporative cooling: spraying water over the patient and using fans to facilitate evaporative and convective heat loss (1)[C]
  – Immerse hands and forearms in cold water.
  – Ice or cold packs on the neck, groin, and axillae (1,2)[C]
• No clear superiority of any one method for heat exhaustion (1)

**MEDICATION**
First Line
No medications are required in the initial management. Use isotonic saline solution to rehydrate (1)[C].
Do not use antipyretics to lower core temperature in heat illness.

Second Line
- For severely ill, consider immunomodulators such as corticosteroids (patients in intensive care unit setting).
- Iced gastric, bladder, or peritoneal lavage
- If disseminated intravascular coagulation (DIC), consider appropriate replacement therapy.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Cool patient immediately (prior to transport even) if heat stroke is suspected or once diagnosed.
- Rapid cooling: Remove clothing, wet patient down, and apply ice packs.
- Emergency treatment; best in a hospital setting

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Rest with legs elevated.

Patient Monitoring
- Rectal temperature monitoring: Cooling may be discontinued when the core temperature drops to 102°F (38.9°C) and stabilizes.
- Heat stroke patients may require airway management, hemodynamic monitoring, and careful fluid and electrolyte administration and monitoring.
- Consider CVP monitoring.

DIET
- Cool or cold clear liquids only (noncarbonated)
- Avoid caffeine.
- Unrestricted sodium

PATIENT EDUCATION
- Proper hydration is the key to prevention.
- Proper conditioning and acclimatization
- Recognize signs and symptoms of heat stress—fatigue and headache.
- Skin exposure facilitates heat loss in hot, humid conditions (use proper sun protection).

PROGNOSIS
- If mental function is not altered and serum chemistries are normal, the prognosis is good and recovery within 24 to 48 hours is typical.
- The mortality rate for heat stroke (10–80%) is directly related to the duration and intensity of hyperthermia as well as to the speed and effectiveness of diagnosis and treatment.

COMPLICATIONS
- May involve failure of any major organ system
- Cardiac arrhythmias or infarction
Pulmonary edema, acute respiratory distress syndrome
Coma, seizures
Acute renal failure
Rhabdomyolysis
DIC
Hepatocellular necrosis

REFERENCES

ADDITIONAL READING

CODES
ICD10
- T67.5XXA Heat exhaustion, unspecified, initial encounter
- T67.0XXA Heatstroke and sunstroke, initial encounter
- T67.3XXA Heat exhaustion, anhydrotic, initial encounter

CLINICAL PEARLS
- Exertional heat stroke is a life-threatening medical emergency that requires immediate whole body cooling (cold/ice water immersion preferred).
- The diagnosis of heat stroke includes an elevated core temperature and signs of CNS dysfunction (e.g., mental status changes, irritability, ataxia, confusion, seizures, or coma).
- Start the cooling process immediately when heat exhaustion is recognized, beginning with wetting the skin with a cool mist and giving oral rehydration solutions if the patient is alert and oriented.
- If in the field (e.g., sporting events, wilderness), cooling should begin immediately (prior to transport if possible).
- Do not rely on oral temperature—a rectal temperature is always preferred.
HEMATURIA
Tracy O. Middleton, DO, FACOFP

**BASICS**

**DESCRIPTION**
Gross (visible) or microscopic (nonvisible) blood in the urine, either symptomatic or asymptomatic

**EPIDEMIOLOGY**

**Prevalence**
- Children: gross: 0.13%; asymptomatic microscopic hematuria (AMH): 0.4–4.1%
- Adults: AMH: 0.9–17%, depending on population

**ETIOLOGY AND PATHOPHYSIOLOGY**

- **Trauma**
  - Exercise induced (resolves within 24 hours of ceasing activity)
  - Abdominal trauma or pelvic fracture with renal, bladder, or ureteral injury
  - Iatrogenic from abdominal or pelvic surgery, indwelling catheters, or foreign body
  - Physical/sexual abuse
- **Neoplasms**
  - Urologic malignancies or benign tumors
  - Endometriosis of the urinary tract (suspect in females with cyclic hematuria)
- **Inflammatory/infectious causes**
  - Urinary tract infection (UTI): most common cause of hematuria in adults
  - Renal diseases: radiation nephritis and cystitis, acute/chronic tubulointerstitial nephritis (due to drugs, infections, systemic disease)
  - Glomerular disease
    - Goodpasture syndrome (antiglomerular basement membrane disease; autoimmune; associated pulmonary hemorrhage)
    - IgA nephropathy
    - Lupus nephritis
    - Henoch-Schönlein purpura
    - Membranoproliferative, poststreptococcal, or rapidly progressive glomerulonephritis (GN)
      - Wegener granulomatosis
    - Endocarditis/visceral abscesses
    - Other infections: schistosomiasis, tuberculosis (TB), syphilis
- **Metabolic causes**
  - Stones (85% have hematuria)
    - Hypercalciuria: common cause of both gross and microscopic hematuria in children
    - Hyperuricosuria
- **Congenital/familial causes**
  - Cystic disease: polycystic, solitary renal cyst
  - Benign familial hematuria or thin basement membrane nephropathy (autosomal dominant)
– Alport syndrome (X-linked in 80%; hematuria, proteinuria, hearing loss, corneal abnormalities)
– Fabry disease (X-linked recessive inborn error of metabolism; vascular kidney disease)
– Nail–patella syndrome (autosomal dominant; nail and patella hypoplasia; hematuria in 33%)
– Renal tubular acidosis type 1 (autosomal dominant or autoimmune)

Hematologic causes
– Bleeding dyscrasias (e.g., hemophilia)
– Sickle cell anemia/trait (renal papillary necrosis)

Vascular causes
– Hemangioma
– Arteriovenous malformations (rare)
– Nutcracker syndrome: compression of left renal vein with renal parenchymal congestion
– Renal artery/vein thrombosis
– Arterial emboli to kidney

Chemical causes
– Aminoglycosides, cyclosporine, analgesics, oral contraceptives, Chinese herbs

Obstruction
– Strictures or posterior urethral valves
– Hydronephrosis from any cause
– Benign prostatic hyperplasia: Rule out other causes of hematuria.

Other causes: loin pain hematuria (most often in young women on oral contraceptives)

RISK FACTORS
– Smoking
– Occupational exposures (dyes, rubber, or tire manufacturing)
– Medications (e.g., cyclophosphamide, pioglitazone therapy >1 year)
– Pelvic radiation
– Chronic infection, especially with calculi
– Recent upper respiratory tract infection
– Positive family history of stones, GN, or cancer
– Chronic indwelling foreign body

DIAGNOSIS

HISTORY
Considerations
– Burning, urgency, frequency: UTI
– Dark cola-colored urine: glomerular origin
– Clots: extraglomerular bleeding
– Arthritis/arthritis/rash: lupus, vasculitis, Henoch-Schönlein purpura
– Flank pain: stones, infarction, pyelonephritis
– Recent upper respiratory infection (URI): poststreptococcal GN, membranoproliferative GN
– Concurrent URI: IgA nephropathy
– Excessive vitamin use: stones
– Marathon runner: traumatic, rhabdomyolysis
– Travel: schistosomiasis, TB
- Painless hematuria and/or weight loss: malignancy
- Family history: Alport disease (hereditary nephritis), sickle cell, polycystic, IgA nephropathy, thin basement membrane disease, von Willebrand
- In patients with microscopic hematuria, any episode of visible hematuria (VH) in the urine, even if transient, is associated with an OR of 7.2 for the prevalence of urologic cancers.

**PHYSICAL EXAM**
Considerations
- Elevated BP, edema, and weight gain: glomerular disease
- Fever: infection
- Palpable kidney: neoplasm, polycystic
- Genitalia: Look for meatal erosion, lesions.

**DIAGNOSTIC TESTS & INTERPRETATION**
A hematuria risk index may assist in stratifying patients at risk for urothelial malignancies who require more intensive testing. High-risk indicators are VH, age >50 years, male gender, and smoking.

**Initial Tests (lab, imaging)**
- If acute cystitis/UTI is ruled out, guidelines recommend evaluating AMH with upper urinary tract imaging and cystoscopy; none recommend cytology or urine markers for initial AMH evaluation (1)[C].
- Urine dipstick (sensitivity 91–100%; specificity 65–99%)
  - False negatives are rare but can be caused by high-dose vitamin C.
  - False positives: oxidizers used to cleanse the perineum, alkaline urine (pH>9), semen; free hemoglobin (hemolysis) and myoglobin (rhabdomyolysis)
  - Heme-negative red urine: food dyes, beets, blackberries, rhubarb, porphyria, rifampin, phenytoin, phenazopyridine may discolor the dipstick, making interpretation difficult.
  - Any proteinuria >2+ raises concern for glomerular disease
- Microscopic urinary analysis should always be done to confirm dipstick findings and quantify red blood cells (RBCs) (1)[C].
  - American Urological Association (AUA) defines clinically significant microscopic hematuria as ≥3 RBCs/high-power field on a properly collected urinary specimen when there is not an obvious benign cause (1,2)[C].
  - Positive dipstick, but a negative microscopic exam should be followed by three repeat tests. If anyone is positive, proceed with a workup (1,2)[C].
  - Exclude factitious or nonurinary causes, such as menstruation, mild trauma, exercise, poor collection technique, or chemical/drug causes, through cessation of activity/cause and a repeat urinalysis (1)[C].
  - RBC casts are pathognomonic for glomerular origin; dysmorphic cells are also suggestive.
- Renal function tests (estimated glomerular filtration rate, blood urea nitrogen, creatinine), albumin, and electrolytes to differentiate intrinsic renal disease and to evaluate for risks for imaging with contrast (1)[C]
  - Indicators of renal disease are significant (>500 mg/day) proteinuria, red cell casts, dysmorphic RBCs, increased creatinine, and albumin:creatinine ratio ≥30 mg/mmol (1,2)[C].
- Urine culture if suspected infection/pyuria
Multidetector CT urography (MDCTU); sensitivity 95%, specificity 92% (3)[C]
- The initial imaging of choice in nonpregnant adults without contraindications to contrast or radiation with unexplained hematuria per the AUA and the American College of Radiology (ACR) (1,3)[C]
- Highly specific and relatively sensitive for the diagnosis of upper urinary tract neoplasms, especially when >1 cm (3)[C]
- Higher radiation dose; weigh risk of disease versus risk of radiation exposure. The DETECT trial suggested that due to the lower risk of upper tract urinary cancers in patients with AMH, CTU can safely be replaced with renal & bladder ultrasound along with cystoscopy. They still suggested CT in patients with suspected stones and MDCTU in those with macroscopic hematuria (4)[B].
- Does not obviate the need for cystoscopy, particularly in high-risk patients (3)[C]
- Presence of calculi on noncontrast does not exclude another diagnosis or need for contrast phase.
- Visualization of ureters is discontinuous.
- Less cost-efficient

CT
- Noncontrast CT is preferred first line in adult patients with acute flank pain suspicious of stones.
- Perform unenhanced helical CT for suspected stone disease in children if US is negative (5)[C].
- Perform CT abdomen and pelvis with contrast in children with traumatic hematuria (5)[C].

Renal and bladder US (RBUS)
- Best for differentiating cystic from solid masses
- Sensitive for hydronephrosis; point of care US in the emergency room may help avoid CT in patients with suspected stones.
- No radiation or iodinated contrast exposure
- Cost-efficient
- US can be used first line in patients with contraindications to CTU or at low risk of malignancy (3)[C].
- Sensitivity and negative predictive value (NPV): for renal cancer = 85.7% and 99.9% and for upper tract urothelial cancer = 14.3% and 99.7%
- Poor sensitivity for renal masses <3 cm
- Main disadvantage is inability to fully evaluate the urothelium for transitional cell cancer.

Magnetic resonance urography (MRU)
- High sensitivity/specificity for renal parenchyma; less useful for collecting system or stones
- Can be used in patients with contraindications to MDCTU (2,3)[C]

MRI
- Similar to CT in sensitivity for renal masses
- No radiation exposure
- Least cost-efficient
- Limited ability to reliably detect urinary tract calcifications (3)[C]
- Can be combined with retrograde pyelogram (RPG) for patients who cannot tolerate MDCTU or MRU (2)[C]

Follow-Up Tests & Special Considerations
- Other tests depend on suspected etiology: sexually transmitted diseases testing, antineutrophil
cytoplasmic antibody (ANCA), C3, C4, antistreptolysin O (ASO) titer, hemoglobin electrophoresis, prothrombin time (PT)/international normalized ratio (INR) for patients on warfarin.

- Consider genetic testing in patients suspected of having familial hematuria.
- Voided urine cytology (sensitivity 43.5%; specificity 95.7%; positive predictive value 47.6%; negative predictive value 94.9%)
  - Not recommended for routine evaluation of AMH; may be considered in those with significant risk factors for urinary malignancy (1,2)[C]
- Insufficient evidence to recommend routine use of urinary tumor markers (6)[C]
- Malignancies are more likely in patients with VH than in patients with nonvisible hematuria (13.8% vs. 3.1%).
- Summary positive predictive value of VH for bladder/renal cancer in age >15 years is 5.1%; risk increases with age and male gender.

**Diagnostic Procedures/Other**

- Flexible cystoscopy (sensitivity 62%; specificity 43–98%)
  - Best for evaluation of bladder, especially small urothelial lesions; NPV for bladder tumors is 99%.
  - AUA recommends all patients with hematuria who are ≥35 years of age and all patients with risk factors for bladder cancer regardless of age to receive cystoscopy in addition to imaging (1,2)[C].
- Renal biopsy
  - Not routine but may be necessary to diagnose GN or in the face of increasing renal insufficiency
- RPG
  - Reserved for patients in which findings on MDCTU are equivocal or in addition to US or noncontrast studies in patients who are contraindicated for contrast or MRI (2,3)[C]
  - Sensitive for small lesions of supravesicular collecting system
  - Requires cystoscopy
- Ureteroscopy/pyeloscopy
  - For visualization of suspected supravesical collecting system lesions
  - Biopsy, excision, fulguration, or extraction of lesions/stones possible
  - Requires anesthesia and cystoscopy
  - Risk of injury to collecting system

**Pregnancy Considerations**

US is initial imaging choice for pregnant patients (3)[C]. MRU or RPG combined with either MRI or US are alternatives (2)[C].

**Pediatric Considerations**

- Consider UTI, GN, Wilms tumor, child abuse, hyperuricemia, hypercalciuria, and familial causes
- The American Academy of Pediatrics section on nephrology has a Choosing Wisely recommendation that states that a workup for hematuria should not be initiated for hematuria in a pediatric patient before repeating a dipstick urinalysis. In patients with persistent ASM, most common diagnoses on renal biopsy are hypercalciuria (30–35%), hyperuricemia (5–20%), and glomerulonephritides, such as IgAN and thin basement membrane disease.
Gross or symptomatic hematuria needs a full workup.
- If eumorphic RBCs, consider UTI, hypercalciuria, familial causes, or masses, stones, or cysts. Obtain a family history, urine culture, US, and urinary Ca:Cr ratio. Urine Ca:Cr ratio >0.2 (mg/mg) is suggestive of hypercalciuria in children >6 years of age (7)[C].
- If dysmorphic RBCs, consider renal consult, especially if associated proteinuria, elevated blood pressure, edema, or a positive family history.

Renal US identifies most congenital and malignant conditions; CT is reserved for cases of suspected trauma (with contrast) or stones (without contrast) (5)[C].

TREATMENT

MEDICATION
None indicated for undiagnosed hematuria

ISSUES FOR REFERRAL
- Nephrology referral for proteinuria, red cell casts, elevated serum creatinine, and albumin:creatinine ratio ≥30 mg/mmol (2)[C]
- Urology referral for stones, vascular/anatomic anomalies, or nutcracker syndrome

SURGERY/OTHER PROCEDURES
Clots may require continuous bladder irrigation with a large-bore Foley catheter to prevent clot retention.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Some experts still recommend periodic urinalysis; recent literature suggests that, after thorough initial negative investigations (imaging, cystoscopy), no follow-up is indicated for the patient with AMH unless symptoms or frank hematuria develop. AUA recommends annual urinalyses in these patients, until two consecutive are negative and the consideration for a repeat workup at 3 to 5 years if hematuria is persistent (1,2)[C].

DIET
Increased fluids for stones or clots

PROGNOSIS
- Generally excellent for common causes of hematuria
- Poorer for malignant tumors and certain types of nephritis
- Persistent AMH is associated with an increased risk of end-stage renal disease in patients aged 16 to 25 years.

Algorithm: Hematuria

CODES

ICD10
- R31.9 Hematuria, unspecified
- R31.1 Benign essential microscopic hematuria
- R31.0 Gross hematuria

CLINICAL PEARLS
- Screening asymptomatic patients for microscopic hematuria is an “I” recommendation from the USPSTF.
- AMH and hematuria persisting after treatment of UTIs must be evaluated.
- Patients with bladder cancer can have intermittent microscopic hematuria; a thorough evaluation in high-risk patients is needed after just one episode.
- In patients with AMH, a history of anticoagulant use does not preclude the need for an evaluation and any new hematuria in patients on anticoagulants requires full evaluation including imaging and cystoscopy (1)(C),(6).
- Signs of underlying renal disease indicate the need for a nephrologic workup, but a urologic
evaluation is still needed in the presence of persistent hematuria (2)[C].
HEMOCHROMATOSIS
Alethea Y. Turner, DO ● Bradley Holman Glenn, MD

**BASICS**

**DESCRIPTION**
Hereditary hemochromatosis (HHC) is a common genetic disease with autosomal recessive inheritance that results in iron overload and subsequent deposition into various tissues.

- HHC includes at least four types of iron overload conditions, which involve gene mutations that alter iron metabolism.
- There is no mechanism to excrete excess iron, so the surplus is stored in tissue, including the liver, pancreas, and heart, eventually resulting in severe damage to the affected organ(s).
- Patients are often asymptomatic, but early clinical features can include fatigue, malaise, arthralgia, and decreased libido.
- Late effects may include diabetes, liver cirrhosis, hypermelanotic pigmentation of the skin, porphyria cutanea tarda, cardiomyopathy, and cardiac arrhythmias.
- Cirrhosis may ultimately result in hepatocellular carcinoma.
- Synonym(s): bronze diabetes; Troisier-Hanot-Chauffard syndrome

**EPIDEMIOLOGY**

**Incidence**
- Predominant age: Metabolic abnormality is congenital, but symptoms typically present between the 3rd and 5th decades for HHC types 1, 3, and 4; type 2 juvenile hemochromatosis typically presents between the 1st and 3rd decades of life, and neonatal presentation is exceedingly rare.
- Predominant sex: Gene frequency is equal between male and female, although clinical signs are more frequent in men.

**Prevalence**
- Prevalence in the United States for carrying an HFE gene mutation (type 1 HHC) is 5.4% for the C282Y gene and 13.5% for the H63D gene; prevalence for homozygosity is 0.3% for C282Y and 1.9% for H63D (1).
- Type 1 accounts for >90% of HHC cases in the United States and primarily occurs in people of northern European descent; ~1 in 200 white adults in the United States are C282Y homozygous (1,2).

**Pediatric Considerations**
Juvenile (type 2) HHC is rare but can present in young patients (between 1st and 3rd decades of life) with hypogonadism and cardiomyopathy.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- HHC type 1 is caused by mutations in the HFE gene (most commonly C282Y and/or H63D),
- type 2 by mutations in either the HJV or HAMP gene, type 3 by mutations in the TFR2 gene, and type 4 by mutations in the SLC11A3 gene.
- Types 1 to 3 involve a deficiency in an iron-regulating hormone named hepcidin, which causes increased intestinal absorption of iron through excessive expression of ferroportin (a
transmembrane protein that transports iron out of the cell and into the bloodstream).

- Type 4 is caused by an insensitivity of ferroportin to hepcidin (4a) or an inactivity of ferroportin itself (4b); the latter leads to iron accumulation within mesenchymal tissue.
- Other rare types of HHC exist as a result of different gene mutations.
- Increased plasma iron and transferrin saturation leads to elevated levels of unbound iron, which are then absorbed into various tissue, eventually causing organ dysfunction.

**Genetics**
- Genetically heterogeneous disorder of iron overload; types 1, 2, and 3 are autosomal recessive; type 4 is autosomal dominant.
- Penetrance is incomplete; expressivity is variable; ~13.5% disease penetrance of C282Y homozygosity (CI 13.5%) (3)
- Factors contributing to variable expressivity include different mutations in the same gene, mitigating or exacerbating genes, and environmental factors.

**RISK FACTORS**
- Family history
- White men between the ages of 30 and 50 years (particularly for HFE-related HHC)
- Loss of blood, such as that which occurs during menstruation and pregnancy, delays the onset of symptoms in women.
- Alcohol consumption because it increases the absorption of iron and synergistically damages the liver along with the oxidative effects of iron

**GENERAL PREVENTION**
First-degree relatives of those with HHC should be screened; typically, with fasting transferrin saturation and ferritin levels

**ALERT**
Screening of the general population is not recommended because only a small subset of patients with HHC will develop symptoms or advanced disease (2,4)[B].

**COMMONLY ASSOCIATED CONDITIONS**
See “Complications.”

**DIAGNOSIS**

**HISTORY**
- Fatigue
- Weakness
- Arthralgias
- Abdominal pain
- Loss of libido or impotency
- Symptoms of diabetes
- Skin pigmentation or blistering
- Dyspnea on exertion

**PHYSICAL EXAM**
- Hepatomegaly and/or splenomegaly
Increased skin pigmentation
- Hepatic tenderness
- Peripheral edema
- Jaundice
- Gynecomastia
- Ascites
- Testicular atrophy
- Hepatic tenderness

**DIFFERENTIAL DIAGNOSIS**
- Inflammatory syndromes
- Various causes of hepatitis
- Biliary or alcoholic cirrhosis
- Repeated transfusions
- Sideroblastic anemia
- β-Thalassemia major

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
There is currently no evidence to support a concrete relationship between symptoms and the degree of iron overload (1).

- Serum ferritin (SF): ≥300 μg/L for men and postmenopausal women and 200 μg/L for premenopausal women; may be elevated for a number of other reasons including but not limited to inflammation (consider checking inflammatory markers); if elevated with suspicion of hemochromatosis, obtain fasting transferrin saturation.
- Fasting transferrin saturation (serum iron concentration ÷ total iron-binding capacity × 100) is the earliest biochemical marker to be increased in HHC: ≥45% is suspicious for HHC but warrants further evaluation because it can be elevated in other disease processes including chronic anemias.
- Confirmatory testing should be done through HFE gene mutation analysis (2).

**Follow-Up Tests & Special Considerations**
- After the diagnosis is established, check the following to determine need for phlebotomy:
  - Aspartate aminotransferase (ALT) and alanine aminotransferase (AST)
  - HbA1c to rule out diabetes
  - Electrocardiogram to evaluate an arrhythmia
  - Echocardiogram if concerned for cardiomyopathy
  - Total testosterone if symptoms of hypogonadism are present
- Consider screening for osteoporosis in patients >50 years with additional risk factors (i.e., alcohol or tobacco use) (2).
- Test for viral hepatitis if transaminitis exists to rule out concomitant disease.
- Monitor for liver lesions with an abdominal ultrasound every 6 months if severe liver fibrosis or cirrhosis is present (2).

**Diagnostic Procedures/Other**
- Liver biopsy or hepatic MRI should be done to measure liver iron content if hepatomegaly is present, SF is >1,000 μg/L, and/or ALT/AST are elevated.
Consider liver biopsy in these cases to determine the degree of liver damage and prognosis (2,4)[C]; SF <1,000 μg/L, normal AST, and the absence of hepatomegaly have a negative predictive value of 95% for severe fibrosis or cirrhosis (3).

**Test Interpretation**
- MRI signal intensity of liver to muscle should be <0.88 in the setting of high iron content (~87% sensitive, 90% specific) (3).
- Liver biopsy will reveal increased hepatic parenchymal iron stores and evidence of any fibrosis or cirrhosis.

**TREATMENT**

**GENERAL MEASURES**
Due to a lack in evidence-based data, there is debate regarding when treatment should be initiated (particularly in asymptomatic patients), what the target serum indices, and frequency of phlebotomy should be. American and European liver associations recommend initiating treatment when SF is above the normal limit (see “Initial Tests (lab, imaging)”). If HCC diagnosis is confirmed, there is no liver involvement, SF remains normal, and the patient is asymptomatic, it is reasonable to monitor SF at least annually (2)[C].
- Phlebotomy (~500 mL per session) is the mainstay of therapy and is performed once or twice weekly in the initial treatment phase and may take up to 2 to 3 years to deplete iron stores (1,4)[C].
- When the patient finally becomes iron deficient, a lifelong maintenance program of ~2 to 6 phlebotomies a year is required to keep iron storage normal or below normal (3,4)[C].
- Erythrocytapheresis is an alternative to phlebotomy because it involves removing only red cells from the blood; however, it is expensive, not widely available, and there is no evidence to support a benefit over phlebotomy (1,3).

**MEDICATION**
- If phlebotomy is not feasible or if it is contraindicated (anemia or severe heart disease), a 2nd tier option is chelation therapy with parenteral deferoxamine (contraindicated in severe renal disease) or oral deferasirox (contraindicated in severe hepatic impairment) (2); monitor patients for auditory or visual changes annually if on chelation therapy.
- The daily use of pantoprazole 40 mg has been shown to reduce the number of phlebotomies needed to keep the ferritin level <100 μg/L in HHC patients homozygous for p.C282Y (5)[B].
- Testosterone replacement in men with HHC can improve symptoms of erectile dysfunction and decreased libido (6)[B].
- Hepatitis A and hepatitis B immunizations should be provided if there is no evidence of previous exposure (2)[C].
- Pneumococcal vaccination (PPSV23) should be given if cirrhosis is present (2).

**ALERT**
Caution is advised for prescribing androgens in the setting of hypogonadism secondary to risk of hepatotoxicity (2).

**First Line**
Phlebotomy, as outlined above
Second Line
Chelation therapy, as outlined above

ISSUES FOR REFERRAL
- Refer to a gastroenterologist if liver biopsy is indicated and for the management of concomitant liver disease.
- Refer to a cardiologist if cardiac involvement is suspected.
- Refer to endocrinology if male infertility is present.

ADDITIONAL THERAPIES
Experimental treatments with hepcidin mimetics to decrease intestinal iron absorption and to reduce levels of iron from the reticuloendothelial system are being researched.

SURGERY/OTHER PROCEDURES
Liver transplant is indicated in end-stage liver disease.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Need for hospitalization is typically rare and necessary only for the management of severe complications including need for organ transplant.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Measure hematocrit before each phlebotomy; skip phlebotomy if hemoglobin is <11 g/dL (2).
- In the initial phases of treatment, check SF every 3 months (3,4).
- Once iron stores are depleted, phlebotomy every 1 to 6 months (adjusted based on patient’s need) should be performed to maintain SF between 50 and 100 μg/L; consider targeting SF to <50 μg/L (3).
- During maintenance therapy, measure transferrin saturation and SF yearly.

DIET
- Avoid consumption of iron-fortified foods, oysters, uncooked shellfish, vitamin C, and iron-containing supplements (2)[C].
  - Natural sources of vitamin C and iron are considered safe (2,4).
- Black tea chelates iron and may be drank with meals (2)[C].

PATIENT EDUCATION
- Adequate hydration prior to phlebotomy is recommended (2).
- Blood collected through phlebotomy may be donated (3,4).
- https://www.hemochromatosis.org/

PROGNOSIS
- Patients diagnosed and treated before the development of cirrhosis or diabetes have a normal life expectancy (2).
- Life expectancy is reduced in patients with cirrhosis and/or diabetes (4).
- Cirrhosis is associated with an increased risk of hepatocellular carcinoma (annual incidence of
3–4%) and mortality (4).

- Cirrhosis is irreversible; arthralgias and symptoms of hypogonadism may not improve with phlebotomies, but other symptoms and complications may be averted with successful management (2,4).

COMPLICATIONS
Complications develop as a result of untreated HHC.
- Arthritis, chondrocalcinosis
- Diabetes mellitus
- Hypogonadism
- Arrhythmia
- Congestive heart failure
- Cirrhosis (prevalence of 20–45% in C282Y homozygotes with SF >1,000 μg/L) (4)
- Hepatocellular carcinoma
- Osteoporosis
- Infection from Listeria monocytogenes, Yersinia enterocolitica, or Vibrio vulnificus is rare, but those with iron overload are at increased risk (4).

REFERENCES

ADDITIONAL READING

CODES
ICD10
- E83.110 Hereditary hemochromatosis
- E83.118 Other hemochromatosis
- E83.111 Hemochromatosis due to repeated red blood cell transfusions
CLINICAL PEARLS

- Types 1 to 3 involve a deficiency in an iron-regulating hormone (hepcidin), which causes increased intestinal absorption of iron.
- Type 4 is caused by an insensitivity of ferroportin to hepcidin (4a) or an inactivity of ferroportin itself (4b); the latter leads to iron accumulation within mesenchymal tissue.
- Screening of the general population for hemochromatosis is not recommended, but testing is recommended if there is clinical suspicion or family history.
- An elevated transferrin saturation is the earliest abnormality in hemochromatosis. Ferritin is a sensitive measure of iron overload but can be elevated in a variety of infectious and inflammatory conditions without iron overload being present.
- Genetic testing is recommended to confirm type 1 hemochromatosis, which is the most common type.
- Patients with hemochromatosis who have hepatomegaly, transaminitis, and/or serum transferrin >1,000 μg/L should be evaluated for liver iron content via MRI or liver biopsy; liver biopsy is necessary to determine degree of liver damage and clarify prognosis.
- Initiate once or twice weekly phlebotomy when SF levels are elevated, particularly when symptoms or clinical findings are present.
- Goal is to achieve and then maintain SF levels 50 to 100 μg/L and possibly even <50 μg/L; maintenance phlebotomy is less frequent and patient specific.
- Consider adding a daily proton pump inhibitor because it may reduce the overall number of phlebotomies.
HEMOPHILIA
Toussaint L. Mears-Claarke, MD

BASICS

DESCRIPTION
- Deficiency of factor VIII (hemophilia A) or factor IX (hemophilia B) coagulation proteins leading to bleeding tendencies in affected individuals. The majority of cases are due to inherited genetic mutations in factor VIII or factor IX coagulation proteins. However, an estimated 30% of all hemophilia cases result from spontaneous mutations.
- Hemophilia A and B are clinically indistinguishable but can be differentiated by assays that detect levels of factors VIII and IX, respectively.
- Disease severity correlates with the relative levels of coagulation factors present in serum analysis:
  - Severe: frequent spontaneous bleeding (factor activity <1%)
  - Moderate: bleeding with mild to moderate trauma (factor activity 1–5%)
  - Mild: bleeding with major trauma, tooth extraction, or surgery (factor activity 5–40%)
- Bleeding frequency is similar in hemophilia A and B with similar levels of factor deficiency.

EPIDEMIOLOGY
- Worldwide, an estimated 400,000 people are affected with hemophilia; estimated frequency of 1 in 10,000 births (1)
- Hemophilia A represents 80–85% of the total hemophilia population; hemophilia B comprises the remaining 15–20%.

ETIOLOGY AND PATHOPHYSIOLOGY
- Damage to vascular endothelium leads to exposure of subendothelial tissue factors, which interact with platelets, plasma proteins, and coagulation factors to produce a localized platelet plug contributing to hemostasis. Complexes involving factors VIII and IX participate in the intrinsic coagulation pathway to activate factor X, FXa. Downstream interactions involving FXa culminate in the conversion of prothrombin to thrombin, mediating platelet activation and fibrin deposition necessary for stabilization of the platelet plug.
- Deficiencies of factor VIII or factor IX result in decreased production of FXa, leading to an unstable platelet plug and impaired hemostasis.

Genetics
- Exhibits an X-chromosome linked inheritance pattern. Males are almost exclusively affected; females are asymptomatic carriers, unless their factor activity is <40% of normal.
- Carriers with symptomatically low clotting factor levels are treated similarly to patients with the trait:
  - May bleed at the time of surgery
- Males within the same family share similar deficiencies and level of severity owing to the same genetic defect.

GENERAL PREVENTION
- Patients should carry medical ID tags listing their bleeding disorder or factor deficiency,
inhibitor status, type of treatment products used, and initial treatment doses for mild, moderate, or severe bleeding.
- Immediate family members of affected patients should have factor VIII and IX levels checked prior to invasive procedures, childbirth, and if bleeding tendencies occur.
- Genetic testing should be offered to at-risk female family members to facilitate genetic counseling.
- Regular dental care and good oral hygiene are recommended to prevent gum bleeding.

DIAGNOSIS

- History and initial presentation
  - 2/3 of presenting hemophilic patients have a positive family history. All male infants born to known carriers should have factor level testing.
  - Prolonged bleeding with circumcision, dental work, surgery, or injury
  - Excessive or easy bruising in early childhood
  - Spontaneous bleeding, especially in joints, muscle, or soft tissue
  - Typical age of presentation: mild (36 months), moderate (8 months), severe (1 month)
  - Pregnancy considerations: Treat all males born to a carrier as if they have hemophilia; recommend planned caesarean delivery if male infant is potentially affected. Avoid fetal scalp electrode placement, vacuum/forceps deliveries.
  - Test infant at birth (2)[B]. Cord blood can be used for testing (3)[A].

- Life-threatening bleeds
  - Intracranial hemorrhage: generally resulting from trauma; incidence of 1:10; fatal in 30% of cases
  - Hematomas of bowel wall can cause obstruction or intussusception and pain mimicking appendicitis.
  - Neck or throat bleeds: can lead to airway obstruction

- Serious bleeds
  - Hemarthrosis, most commonly of ankles, elbows, and knees
    - Infants may present with irritability or decreased use of limb.
    - Adults may have prodromal stiffness, acute pain, and swelling of joint.
    - Arthropathy results from repeated bleeding into joints, damaging cartilage, and subchondral bone:
      - Can result in fixed joints, muscle wasting, and significantly impaired mobility
  - Muscular hematomas most commonly occur in quadriceps, iliopsoas, and forearm:
    - May result in compartment syndrome and ischemic nerve damage, such as femoral nerve neuropathy due to undetected retroperitoneal hemorrhage
  - Mucous membrane bleeding, such as in the genitourinary tract, leading to hematuria
  - Pseudotumor syndrome: untreated hemorrhage causing a hematoma, which calcifies (named because it can be mistaken for cancer)

DIFFERENTIAL DIAGNOSIS

- von Willebrand disease
- Vitamin K deficiency, anticoagulant (i.e., warfarin, rivaroxaban, heparin) therapy (factor IX is vitamin K dependent)
- Other factor deficiencies (i.e., hemophilia C, acquired hemophilia A), afibrinogenemia,
dysfibrinogenemia, fibrinolytic defects, platelet disorders
• Child abuse

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Screening tests: CBC with platelet count, PT, aPTT, platelet function (preferred), or bleed time
  – aPTT usually prolonged. aPTT may be normal in patients with mild hemophilia.
  – PT, platelet count, and function are normal.
• Follow-up tests: mixing study, vWF, factor activity levels (factor VIII:C and factor IX)
  – Mixing study: Patient’s plasma is mixed with pooled normal plasma. Prolonged aPTT corrects in absence of inhibitors, that is, lupus anticoagulant and acquired factor inhibitors.
  – vWF is normal.
• Diagnosis based on factor VIII:C or IX activity
  – Normal factor levels: 50 to 150 IU/dL
  – Mild: 5 to 40 IU/dL
  – Moderate: 1 to 5 IU/dL
  – Severe: <1 IU/dL

Follow-Up Tests & Special Considerations
• Genetic counseling, and participation in genotyping project for affected individuals and family, is recommended; the information may help predict inhibitor risk, bleeding severity, and individualize treatment (4)[A].
• Inhibitors to factor VIII and IX (see “Complications”):
  – Should be periodically measured using the Nijmegen or Bethesda assay, which quantifies the alloantibody titer
  – Screen before invasive procedures and at regular intervals.

Diagnostic Procedures/Other
Prenatal diagnosis via genetic testing of a sample of chorionic villus or fluid obtained at amniocentesis is not recommended (2)[B].

Test Interpretation
Pathology of affected joints: synovial hemosiderosis, articular cartilage degeneration, thickening of periarticular tissues, bony hypertrophy

TREATMENT

GENERAL MEASURES
• Integrated, multidisciplinary, comprehensive care model, including hematologist, physical therapist, and social worker, is recommended (1,5)[A].
• Avoid aspirin or other NSAIDs.
• Treat early; acute bleeds should be treated as quickly as possible, preferable within 2 hours (1) [A].
• For surgical prophylaxis
  – If major surgery is undertaken, factor levels should be maintained at >50% for at least 2 to 3 weeks after the procedure:
Fibrin glue products may be beneficial for oozing.
– Dental extractions: Antifibrinolytics (Amicar, tranexamic acid) may be used.
– Minor procedures: may use desmopressin (DDAVP) in hemophilia A

Hepatitis A and B vaccinations are recommended.
Encourage physical activity: Patients should avoid high-impact contact sports. Organized sports should be encouraged (1)[A].

MEDICATION

First Line

Principles of therapy
– Primary prophylaxis: administration of specific factor replacement therapy in the absence of bleeding to maintain adequate baseline plasma levels sufficient for hemostasis in all categories of severity (1)[A]

  o Lower frequency of acute bleeds and episodes of life-threatening hemorrhage compared to on-demand therapy
  o Standard of care for children with severe hemophilia A or B to prevent joint bleeds and joint degeneration

  o Additionally, bispecific monoclonal antibody for FIXa and FX (emicizumab-kxwh) is available for prophylaxis for hemophilia A with/without inhibitors (6)[B].

  o Dosing, frequency, duration of therapeutic regimens tailored to individual patient needs in clinical practice

  o Gene therapy is currently under development to reduce the risk of bleeding (7)[B].

– On-demand therapy: treatment administered in response to occurrence of bleeding (1)[A]

  o Amount and duration of factor replacement depends on location and severity of bleeding:
    ■ Mild bleeds correct to a factor level of >30% major hemorrhages, and large muscle bleeds require correction to levels between 50% and 100%.
    ■ Life-threatening bleeds require levels between 80% and 100%, sustained with bolus dosing or continuous infusion.

Specific agents:
– Hemophilia A: Replacement with factor VIII concentrates is the treatment of choice: two sources for the factor available (1)[A]:

  o Purified plasma-derived factor VIII: Donor pool is screened, and the plasma-derived factor is treated to inactivate viruses (HIV, hepatitis B, and hepatitis C). Theoretical risks still exist.
  o Recombinant factor VIII
    ■ Dosing: 1 IU of factor VIII (the amount in 1 mL of plasma)/kg body weight administered will raise the plasma level of the recipient by 2%.

– Hemophilia B: Replacement with factor IX concentrates is the treatment of choice:

  o Plasma-derived factor IX and recombinant factor IX (preferred) are commercially available.
    ■ Dosing: 1 IU/kg body weight administered will raise plasma factor IX levels 1%.

Hemophilia patients with inhibitors (neutralizing alloantibodies to factors VIII or IX) (1)[A]
– Inhibitor formation should be suspected when replacement with the deficient factor fails to correct coagulopathy.
– Low-titer (<5 BU/mL) patients: Replace with high doses of the deficient factor to overcome the circulating inhibitor concentration.
High-titer patients: Treat using products that bypass the factor neutralized by the alloantibody or emergently with high doses of the specific deficient factor:
  - Two bypassing agents are available; both are efficacious at providing 80% of bleeding episodes:
    - Activated prothrombin complex concentrate
    - Recombinant activated factor VII

Immune tolerance induction (ITI): protocols to promote immune tolerance through repeated exposure to high-dose factor VIII therapy over 12 to 18 months, with or without immunosuppressive therapy (corticosteroids, cyclophosphamide, rituximab). Success rates are 60–80%.

Home therapy allows immediate access to clotting factor, resulting in decreased pain, dysfunction, and long-term disability (2)[B].

Second Line

- Cryoprecipitate and fresh frozen plasma (FFP) can be used in instances where the specific factor concentrate is unavailable for emergent hemostasis.
  - FFP: contains all coagulation factors but generally difficult to attain high levels of factors VIII or IX
    - Starting dose: 15 to 20 mL/kg
  - Cryoprecipitate: derived from precipitates of cooled FFP; contains significant levels of factor VIII (up to 100 IU/bag) but not factor IX:
    - Dosing: 1 mL cryoprecipitate has ~3 to 5 IU factor VIII.

- Desmopressin (DDAVP): synthetic vasopressin; stimulates endogenous release of factor VIII (and vWF) from endothelial stores; used in mild hemophilia A
  - IV or SC: 0.3 μg/kg infused 30 minutes prior to procedure; may repeat if needed
  - Intranasal (150 μg/spray): adult dose, 1 spray to each nostril (300 μg total). Alternate dose if <50 kg: 150 μg once.
  - Adverse effect: hyponatremic seizures, especially in children; restrict fluids and watch sodium levels and urine output.

- Antifibrinolytic agents: inhibit plasminogen activation, thereby stabilizing the clot
  - Effective in controlling mucosal bleeding, such as bleeding in oral cavity, epistaxis, and menorrhagia; can also be used prophylactically (e.g., prior to tooth extractions)
    - Tranexamic acid (25 mg/kg PO q6–8h or 10 mg/kg IV q6–8h)
    - Aminocaproic acid (Amicar) is less frequently used.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Regular evaluations every 6 to 12 months, including a musculoskeletal evaluation, an inhibitor screen, liver tests, and tests for antibodies to hepatitis viruses and HIV

PATIENT EDUCATION

- National Hemophilia Foundation: http://www.hemophilia.org/
- World Federation of Hemophilia: http://www.wfh.org/
- Center for Disease Control and Prevention:
PROGNOSIS
- Survival is normal for those with mild disease; mortality is increased 2- to 6-fold in those with moderate to severe disease.
- Intracranial hemorrhage is a leading cause of death in hemophilia.
- Hemophilic arthropathy is the main cause of morbidity in patients with severe hemophilia.

COMPLICATIONS
- Hemophilic arthropathy: Symptoms include pain, limitation of motion, and contractures.
- Theoretical transmission of blood-borne infections, such as hepatitis A, B, C, and D and HIV; this risk has been greatly reduced with current testing of blood products.
- Development of inhibitor autoantibodies
  - More common in hemophilia A (20–30% of patients with severe hemophilia compared to 5% in hemophilia B) and in patients with severe disease requiring multiple transfusions
  - In severe hemophilia A, inhibitors develop by median age of 3 years; in mild/moderate hemophilia, inhibitors develop by median age 30 years.
  - Risk of inhibitor development in hemophilia B associated with family history and/or specific genetic defects
  - High incidence (up to 50%) of severe allergic reactions, including anaphylaxis, with factor IX administration in hemophilia B patients with inhibitors
  - No increased risk of bleeding, but when bleeding occurs, it is more difficult to achieve hemostasis due to decreased response to factor replacement.

REFERENCES

ADDITIONAL READING

CODES
ICD10
- D66 Hereditary factor VIII deficiency
- D67 Hereditary factor IX deficiency
- Z14.01 Asymptomatic hemophilia A carrier

CLINICAL PEARLS
- Deficiency of factor VIII (hemophilia A) or factor IX (hemophilia B) coagulation proteins leading to bleeding tendencies in affected individuals
- The majority of hemophilia cases are due to inherited genetic mutations in factor VIII or factor IX.
- An estimated 30% of all hemophilia cases result from spontaneous mutations.
- Exhibits an X-chromosome linked inheritance pattern. Males are almost exclusively affected.
- Diagnosis based on decreased factor VIII:C or IX activity
- Initial site of bleeding and bleeding severity dependent on coagulation factor levels
- Survival is normal for those with mild disease; mortality is increased 2- to 6-fold in those with moderate to severe disease.
HEMORRHOIDS
Donna I. Meltzer, MD

BASICS

DESCRIPTION
- Varicosities of the hemorrhoidal venous plexus
- External hemorrhoids
  - Located below the dentate line; visceral innervation (painful)
  - Covered by squamous epithelium
- Internal hemorrhoids
  - Located above the dentate line; somatic innervation (painless)
  - Covered by columnar epithelium
  - Classification of internal hemorrhoids (1):
    o Grade I: Hemorrhoid vessel bulges without prolapse.
    o Grade II: Hemorrhoid prolapses with straining but reduces spontaneously.
    o Grade III: Hemorrhoid prolapses with straining and requires manual reduction.
    o Grade IV: chronically prolapsed—can’t be reduced
- Internal and external hemorrhoids often coexist.
- Although often asymptomatic, hemorrhoids can present with itching, bleeding, soilage, prolapse, or pain.
- Pain and thrombosis more common with external than internal hemorrhoids.

Geriatric Considerations
Hemorrhoids and rectal prolapse are more common in elderly.

Pediatric Considerations
- Uncommon in infants and children; most common cause is chronic liver failure; other findings (rectal polyps, skin tags, condyloma) often misdiagnosed as hemorrhoids
- In adolescents, chronic constipation and prolonged toilet time can result in hemorrhoids.

Pregnancy Considerations
- Common in pregnancy
- Usually resolves after delivery
- No treatment required, unless extremely painful

EPIDEMIOLOGY
- Predominant age: adults; peak from 45 to 65 years (2)
- Predominant sex: male = female

Incidence
Common; over 3.5 million office visits per year are related to hemorrhoidal disease

Prevalence
- ~4–5% in general population in the United States
- 39% prevalence on routine screening colonoscopy (2)
ETIOLOGY AND PATHOPHYSIOLOGY
- Exact pathophysiology is unknown.
- There are three primary hemorrhoidal cushions—typically located in left lateral, right anterior, and right posterior positions. Hemorrhoidal cushions augment anal closing pressure and protect the anal sphincter during stool passage. During Valsalva, increased intra-abdominal pressure raises pressure within the hemorrhoidal cushions. Mechanisms implicated in symptomatic hemorrhoidal disease include:
  - Dilated veins of hemorrhoidal plexus
  - Tight internal anal sphincter
  - Abnormal distention of the arteriovenous anastomosis
  - Prolapse of the cushions and the surrounding connective tissues

Genetics
No known genetic pattern

RISK FACTORS
- Pregnancy
- Pelvic space-occupying lesions
- Liver disease; portal hypertension (HTN)
- Constipation
- Occupations that require prolonged sitting
- Loss of perianal muscle tone due to old age, rectal surgery, birth trauma/episiotomy, anal intercourse
- Obesity
- Chronic diarrhea

GENERAL PREVENTION
- Avoid constipation by consuming high-fiber diet (>30 g/day) and ensuring proper hydration.
- Maintain appropriate weight.
- Avoid prolonged sitting or straining on the toilet.

COMMONLY ASSOCIATED CONDITIONS
- Liver disease; cirrhosis, ascites
- Pregnancy
- Constipation

DIAGNOSIS
Diagnosis is typically straightforward through history and inspection of the perineum, rectal exam, and anoscopy.

HISTORY
- Symptoms (1)
  - Bleeding (~60%)
  - Classically, bright red blood per rectum, may range from scant blood on toilet paper to copious blood in the toilet bowl
  - Pruritus (~55%)
– Perianal discomfort (~20%)
– Soiling (~10%)
– Constipation or diarrhea
– Straining with defecation
• External hemorrhoids
  – Episodic bleeding on stool or toilet paper, pruritus, and irritation from compromised hygiene and pain
• More extensive internal hemorrhoids
  – Feeling of incomplete evacuation
• Thrombosed hemorrhoids present as acute painful mass.
• Ask about diet (fiber, fluid intake), bowel patterns (frequency, consistency), bowel habits (prolonged sitting), change in stools, systemic symptoms (weight loss, pain, fever).
• Ask about past medical history and family history (gastrointestinal disease, colorectal cancer).

PHYSICAL EXAM
• Visual anorectal inspection with Valsalva maneuver
• Digital exam with anoscopy
  – Internal hemorrhoid appears as purple mass on lumen wall.
  – Examine for additional anorectal pathology (mass, abscess, fissure, fistula).
• Attempt to reduce prolapsed hemorrhoids.
• Abdominal exam to exclude mass
• Peripheral stigmata of cirrhosis and portal HTN (caput, telangiectasias, palmar erythema)

DIFFERENTIAL DIAGNOSIS
• Rectal or anal neoplasia
• Condyloma
• Skin tag
• Inflammatory bowel disease
• Anal fistula, fissure, or abscess
• Rectal polyp
• Rectal prolapse

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Not indicated unless anemia is suspected

Diagnostic Procedures/Other
Sigmoidoscopy or colonoscopy depending on risk factors for malignancy in patients with rectal bleeding

TREATMENT

Prevention
• Fiber supplements
• Stool softeners
• Anal hygiene
GENERAL MEASURES

- Hemorrhoids are a recurrent disease, even after surgical excision. Preventive measures should be continued indefinitely.
- For mild symptoms or prevention
  - Avoid prolonged sitting during bowel movements.
  - Avoid straining.
  - Avoid constipation by eating a high-fiber diet or by taking fiber supplements; if necessary, take regular stool softeners.
  - Regular exercise, weight loss if indicated
- Pruritus or mild discomfort after stooling might respond to topical corticosteroid ointment, anesthetic ointments or sprays, and warm sitz baths.
- Constipation relief, anal hygiene, local ointments, and sitz baths are effective through the stage of easy reduction (grade II). More severe stages often require ligation or surgery.

MEDICATION

First Line

- Dietary modification with adequate fluid (generally ≥2 L water per day) and high fiber (25 to 35 g/day) is first-line, nonoperative therapy for symptomatic hemorrhoids (1).
- Fiber helps relieve overall symptoms and bleeding (3)[A].
- Stool softener or bulk-forming laxative to soften stool
- Sitz bath with warm water for pain relief
- Witch hazel (Tucks) as a wipe after stooling may be useful for astringent properties.
- Topic anesthetics (benzocaine, lidocaine, pramoxine), steroids, emollients to alleviate symptoms; these over-the-counter (OTC) products have been traditionally used but lack strong evidence for long-term use.
  - Local anesthetics for relief of pain and itch; applied to perianal area (not inserted into rectum)
    - Dibucaine 1% ointment (Nupercainal), lidocaine 5% (Preparation H, Tucks), pramoxine 1% foam, ointment, wipe (Proctofoam); benzocaine 20% spray, ointment. Use sprays with caution as alcohol in product may cause burning sensation.
    - Anti-inflammatory agents (corticosteroids) to decrease swelling and for discomfort and itch
      - Hydrocortisone ointment, cream (0.25–2.5%) (Anusol HC, Cortifoam). Rectal suppositories are for short-term use only.
    - Astringents to help dry skin
      - Witch hazel solution, wipes, pads (Preparation H, Tucks)
    - Vasoconstrictors to shrink hemorrhoids and ameliorate bleeding, pain, itch
      - 0.25% phenylephrine ointment, suppository, gel (Preparation H, Rectacaine)

Second Line

Treatment for special cases

- Thrombosed external hemorrhoids: if present within 72 hours after pain onset, recommend incision and clot evacuation or excision of hemorrhoid complex. Early surgical excision may resolve symptoms faster and lower incidence of recurrence (3)[C].
- Strangulated hemorrhoid: untreated irreducible hemorrhoid can progress to ulceration and thrombosis. Treatment requires urgent or emergent hemorrhoidectomy (4)[A].
- Acute hemorrhoidal bleeding associated with portal HTN can be life-threatening. Treatment should involve medical management and correction of coagulopathy; sclerotherapy, suture
ligation, and surgical shunts (if necessary)

**SURGERY/OTHER PROCEDURES**

- **Indications:** failure of medical and nonoperative therapy, symptomatic grade III or IV hemorrhoids in presence of a concomitant anorectal condition requiring surgery, or patient preference
- **Office-based procedures for patients with grade I or II (or III) internal hemorrhoids who have failed conservative management**
  - Rubber band ligation (RBL) most common and most effective office-based procedure for symptomatic internal hemorrhoids. Avoid if on anticoagulants (3)[A],(5).
  - Infrared photocoagulation: Infrared light waves cause necrosis within hemorrhoid; similar or slightly higher recurrence rates compared to RBL; less postoperative pain and fewer complications (1,2)[A],(3)[B]
  - Sclerotherapy: submucosal injections causing local thrombosis; might be best for patients at increased bleeding risk (anticoagulated, advanced liver disease); care must be taken to inject proper site; not for advanced disease or if evidence of infection, inflammation, and ulceration is present
  - Cryotherapy is no longer recommended due to high rate of complications.
- **Surgery for patients with symptomatic grade III or IV disease who have failed nonoperative treatments (3)[A]**
  - Conventional hemorrhoidectomy
  - Closed hemorrhoidectomy—closure of mucosal defect
  - Open hemorrhoidectomy—tissue removed and mucosal defect left open
  - Different technologies are now used to excise hemorrhoidal tissue: diathermy, lasers, ultrasonic dissectors; associated with less pain.
- **Newer techniques reduce surgical time, early postoperative pain, urinary retention, and time to return to normal activity.**
  - Doppler-guided/assisted hemorrhoidal artery ligation (HAL): Anoscope or proctoscope with Doppler probe identifies hemorrhoidal artery, which is then ligated; favorable in terms of outcome and postoperative pain in advanced hemorrhoidal disease (6)[B]
  - Stapled hemorrhoidopexy—for advanced internal hemorrhoidal disease. Excises submucosa; shorter recovery but more recurrent disease than conventional hemorrhoidectomy (2,5)[A],(6)[B]
  - LigaSure hemorrhoidectomy: reduces operating time, is superior in terms of patient tolerance, and is equal to conventional hemorrhoidectomy in long-term symptom control (2)[A]

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Oral bioflavonoids have shown beneficial effect on bleeding, pruritus, and recurrence (3)[A].
- Topical nifedipine (compounded by pharmacist) can relieve pain of thrombosed hemorrhoids.
- Topical nitroglycerin (0.4%) has been used to decrease anal sphincter spasm in thrombosed hemorrhoids; headache is primary side effect.
- Botulinum toxin injection into anal sphincter to relieve spasm and pain of thrombosed hemorrhoid
- Aloe vera cream on the surgical site after hemorrhoidectomy reduces postoperative pain and decreases healing time and analgesic requirements.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
● Encourage physical fitness, weight management, and dietary compliance.
● Avoid prolonged sitting and straining on the toilet.

Patient Monitoring
As needed, depending on treatment

DIET
High fiber with a target of 30 g of insoluble fiber per day through sources such as wheat bran cereals, oatmeal, peanuts, artichokes, beans, corn, peas, spinach, potatoes, apples, apricots, blackberries, raspberries, prunes, pears, bananas; adequate fluids (6 to 8 glasses of water per day); avoid excessive caffeine

PATIENT EDUCATION

PROGNOSIS
● Spontaneous resolution
● Recurrence

COMPLICATIONS
● Thrombosis
● Ulceration
● Anemia (rare)
● Incontinence
● Pelvic sepsis following hemorrhoidectomy

REFERENCES

ADDITIONAL READING

SEE ALSO
Colon Cancer; Portal Hypertension; Rectal Cancer

CODES

ICD10

K64.9 Unspecified hemorrhoids
K64.0 First degree hemorrhoids
K64.1 Second degree hemorrhoids

CLINICAL PEARLS

Hemorrhoids are very common. Internal hemorrhoids are typically painless. External hemorrhoids are typically painful.

All patients should be encouraged to consume 25 to 35 g of fiber per day.

More advanced hemorrhoidal disease requires intervention with ligation or surgery.
HENOCH-SCHÖNLEIN PURPURA
Jonathan A. Phillips, DO • Laura B. Bishop, MD

BASICS
Increasingly referred to as immunoglobulin-A vasculitis (IgAV)

DESCRIPTION
- Henoch-Schönlein purpura (HSP) is a nonthrombocytopenic, predominantly IgA-mediated, small vessel vasculitis that affects multiple organ systems and occurs in both children and adults.
- HSP is often self-limited, with the greatest morbidity and mortality attributable to long-term renal damage.
- Characterized by a tetrad of purpuric skin lesions, arthralgia, abdominal pain, and nephropathies

EPIDEMIOLOGY
Incidence
- Annual incidence: ranges from 3–27/100,000 children and 0.8–1.8/100,000 adults
- Mean age: 6 years; 90% of patients with HSP are <10 years of age; however, has been reported in patients age 6 months to 75 years old
- Gender: Male-to-female ratio is between 1.2:1 and 1.8:1
- Race/ethnicity: most common in Caucasians and Asians, less common among African Americans

Prevalence
- Annual prevalence: 10 to 22/100,000 persons
- Year-round occurrence; more common in fall

ETIOLOGY AND PATHOPHYSIOLOGY
- Autoimmune disorder in which IgA production is increased in response to trigger(s), IgA1 immune complexes then activate the complement pathway, leading to production of inflammatory cytokines and chemokines.
- IgA-containing immune complex deposition results in small vessel inflammation which leads to fibrosis and necrosis within skin, intestinal mucosa, joints, and kidneys.
- No single etiologic agent has been identified; however, there are some associations (listed below) and a popular theory is one of a multihit model leading to HSP-associated glomerulonephropathy.
  - Infections are suggested by prevalence in the fall and a common upper respiratory infection (URI) prodrome. Associated pathogens include (but are not limited to) group A Streptococcus (may be present in up to 30% of HSP-associated nephritis), parvovirus B19, Bartonella henselae, Helicobacter pylori, Haemophilus parainfluenzae, coxsackievirus, adenovirus, hepatitis A and B viruses, Mycoplasma, Epstein-Barr virus, herpes simplex, varicella, Campylobacter, methicillin-resistant Staphylococcus aureus.
  - Drugs are most often associated with adults with HSP: acetaminophen, angiotensin-converting enzyme inhibitors (ACEI), angiotensin II receptor antagonists (ARB), some
antibiotics including clarithromycin quinolones, etanercept, codeine, nonsteroidal anti-inflammatory drugs
– Vaccinations are rarely reported in association with HSP; however, there are some reports surrounding administration of MMR (measles, mumps, rubella), pneumococcal, meningococcal, influenza, and hepatitis B immunizations.

**Genetics**
Associated with $\alpha_{1}$-antitrypsin deficiency, familial Mediterranean fever, HLA-A2, HLA-A11, HLA-B35, HLA-DRB1, renin-angiotensin, and nitric oxide synthetase polymorphisms.

**COMMONLY ASSOCIATED CONDITIONS**
- Malignancy: this is rare and the greatest association is with solid tumors, including lymphoma, prostate cancer, and non–small-cell lung cancer, but also multiple myeloma.
- Studies suggest a possible relationship with *H. pylori* infection (1) and immune-related disorders (food allergy, drug allergy, inflammatory bowel disease).

---

**DIAGNOSIS**
Palpable purpura/petechiae without thrombocytopenia and at least one of the following:
- Diffuse abdominal pain
- Biopsy with predominant IgA deposition
- Arthralgia or arthritis
- Renal involvement (hematuria or proteinuria)
- Direct immunofluorescence showing IgA deposition (2)[A]

**HISTORY**
- Exposure to possible trigger, including recent infection (particularly URI) or offending drug
- Rash (most common presenting symptom): purpuric, palpable; predominant distribution often symmetric on dependent areas (lower extremities and buttocks). May spread elsewhere, typical duration 3 to 10 days with no definitive temporal association with other symptoms.
- Gastrointestinal (about 50–75% of cases)
  – Nausea/vomiting
  – Abdominal pain (diffuse, colicky, may be transient or constant)
  – Hemaotchezia/melena
- Polyarthritis (about 75% of cases)
  – often symmetric involvement of knees and ankles
- Renal (about 20–55% of cases)
  – Gross hematuria (higher in adults than children)
  – Oliguria or anuria
- Fatigue
- Low-grade fever
- Rare symptoms: periorbital or scrotal swelling, headache, seizures, neuropathy, behavioral changes, hemoptysis

**PHYSICAL EXAM**
- Rash (96% of cases, 74% primary presenting symptom):
  – May start as urticaria, develops into nonblanching, palpable purpura, with or without
petechiae, ecchymoses, and bullae
- Distribution usually symmetric, most commonly involving the lower extremities but may involve the face and trunk
- Abdominal tenderness (66% of cases, 12% primary presenting symptom):
  - Evidence of gastrointestinal (GI) hemorrhage (28% of cases), recommend rectal examination to assess for hematochezia
- Joint tenderness (64% of cases, 15% primary presenting symptom):
  - Mainly affects knees or ankles; may have associated warmth and limited range of motion, less commonly effusion; erythema is absent.
  - Mostly nonmigratory, transient, and nondeforming
- Orchitis (5%):
  - Presents as scrotal swelling and tenderness, may have associated torsion
- Renal disease (<1% primary presenting symptom):
  - Hypertension may be present.
- Rarely, patients present with central nervous system (CNS) or pulmonary involvement, which may manifest as signs of cerebral hemorrhage or diffuse interstitial pneumonia, respectively.
- Lower extremity edema is more common in adults than children.

DIFFERENTIAL DIAGNOSIS
- Infection:
  - Meningococcemia
  - Rocky Mountain spotted fever
  - Bacterial endocarditis
  - Rheumatic fever
  - Epstein-Barr virus
  - Sepsis
- Vasculitides:
  - Polyarteritis nodosa
  - Granulomatosis with polyangiitis
  - Microscopic polyangiitis
  - Systemic lupus erythematosus
  - Kawasaki disease
  - Urticarial vasculitis
  - Cryoglobulinemia-associated vasculitis
- Other:
  - Acute post-streptococcal glomerulonephritis
  - Inflammatory bowel disease
  - Idiopathic thrombocytopenic purpura/thrombotic thrombocytopenic purpura
  - Juvenile idiopathic arthritis/mixed connective tissue disease/juvenile dermatomyositis
  - Leukemia/lymphoma
  - Hereditary hemorrhagic telangiectasia
  - Acute surgical abdomen
  - Child abuse

DIAGNOSTIC TESTS & INTERPRETATION
- No single lab test confirms the diagnosis of HSP.
- Labs directed toward excluding other illnesses and assessing degree of renal involvement
Initial Tests (lab, imaging)
The following are generally accepted as initial labs for HSP:
- **Complete blood count:**
  - Leukocytosis and thrombocytosis may occur. Eosinophilia is common. Thrombocytopenia indicates an alternative cause of purpura.
  - Hemoglobin is variable, depending on whether GI hemorrhage occurs.
- **Basic serum chemistry panel:**
  - Electrolyte imbalances or elevated creatinine indicate renal dysfunction.
- **Urinalysis:**
  - Gross or microscopic hematuria, proteinuria, and red cell casts indicate renal dysfunction.
- **Prothrombin time/international normalized ratio and partial thromboplastin time:**
  - Normal in HSP. Abnormal coagulation studies may indicate an alternative cause of purpura.
- **Imaging** is not part of the routine workup for HSP but may be performed to rule out alternative etiologies or for evaluation of suspected complications, particularly in cases of GI and renal involvement. Initial imaging modalities to consider include the following:
  - Abdominal radiographs, with or without barium enema: to evaluate for free abdominal air suggestive of bowel perforation.
  - Abdominal ultrasound: sensitive for the detection of intramural bleeding in HSP and may also show thickened bowel wall, reduced peristalsis, intussusception.
- **Renal ultrasound:** evaluates for hydronephrosis in cases of renal failure

Follow-Up Tests & Special Considerations
The following labs are also useful in diagnosing HSP:
- **Blood culture:**
  - To rule out sepsis/bacteremia when diagnosis is unclear
- **Acute phase reactants (erythrocyte sedimentation rate (ESR)/C-reactive protein):**
  - Expect mild elevation
- **IgA level:**
  - Often elevated, although nonspecific and nonsensitive
- **Complement levels:**
  - Normal; sometimes decreased
- **Antinuclear antibody/antineutrophil cytoplasmic antibody:**
  - Negative but helps with narrowing ddx
- **Antistreptolysin-O titer:**
  - Evaluates for preceding streptococcal infection
- **Stool guaiac if suspected GI hemorrhage**
- **CT arteriography** may be necessary to identify the location of bleeding in patients with GI hemorrhage.

Diagnostic Procedures/Other
- **Renal biopsy:** Obtain if diagnosis is uncertain or if urinalysis shows nephrotic range proteinuria. Biopsy may show mesangial IgA deposition, mesangial proliferation, or in severe cases, crescentic glomerulonephritis (3)[A].
- **Skin biopsy of purpura:** IgA deposition in the dermis on immunofluorescence
- **Endoscopy** may be considered in cases of GI hemorrhage given symptomatic overlap of HSP with inflammatory bowel disease.
- **Barium enema** may be therapeutic in some instances of intussusception, although surgical
correction is commonly needed.

**TREATMENT**

**GENERAL MEASURES**

Rest and elevation of affected areas may limit purpura. Hydration and nutrition play a supportive role in treatment.

**MEDICATION**

- In the absence of renal dysfunction or complication, HSP is usually self-limited and best managed with supportive care.
- NSAIDs effective for symptomatic joint pain. Caution is advised in cases of renal involvement and consider acetaminophen as an alternative.
- Steroids may be helpful early in disease for patients with severe abdominal pain. Oral prednisone may decrease both duration of abdominal pain and severity of joint pain. This may have benefit in preventing GI bleeding and causes of surgical abdomen, including intussusception (3)[B].
  - Steroids have benefit in treatment of severe and/or bullous purpura.
  - Steroids given early in disease are effective for the acute treatment of crescentic nephritis and may prevent chronic renal disease in such patients.
  - Early steroids have no effect on prevention or development of renal involvement after 1 year.
- Immunosuppressive therapy may be beneficial for patients with evidence of severe renal involvement. There have been many small case studies and case reports showing benefit in these patients. High-dose IV pulse steroids, cyclophosphamide, rituximab, mycophenolate, and plasmapheresis, have all been described in small studies. Consensus for when to definitively use these agents is still controversial and the subject of further research (4)[B].
- ACEI or ARB may be helpful in patients with HSP and persistent proteinuria.

**ISSUES FOR REFERRAL**

- Consider nephrology referral for possible renal biopsy if nephrotic range proteinuria at any time or proteinuria >100 mg/mmol for 3 months after diagnosis.
- Could consider dermatology referral for skin biopsy if diagnosis is unclear

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Admission criteria/initial stabilization
  - Insufficient oral intake
  - Renal insufficiency
  - Severe abdominal pain
  - Severe GI bleeding
  - Altered mental status
  - Mobility restriction due to arthritis
  - HTN
  - Nephrotic syndrome
- IV fluids: Hydration should be maintained.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Patients should be seen weekly during the acute illness. Visits should include history, physical exam (include BP measurement), and urinalysis.
- Because ~100% of patients who develop renal involvement will do so within 6 months of HSP diagnosis, all patients should be followed at least monthly with BP and urinalysis for a duration of at least 6 months.
- Women with a history of HSP should be monitored for proteinuria and HTN during pregnancy.
- Consider workup for occult malignancy in patients with adult-onset HSP.

PATIENT EDUCATION
https://familydoctor.org/condition/henoch-schonlein-purpura/

PROGNOSIS
- Long-term prognosis heavily dependent on presence and severity of nephritis
- HSP is self-limited in 94% of children and 89% of adults.
- Most cases of HSP resolve within 4 weeks of diagnosis. Recurrence rate within 6 months of diagnosis is 33%.
- Factors associated with poorer prognosis include age >8 years, fever at presentation, purpura above the waist, elevated ESR or IgA concentration, and increasing severity of renal histology grade.
- Chronic renal disease occurs in up to 20% of children with nephritic and nephrotic syndrome compared with 50% of adults who had any renal involvement. Risk of long-term renal failure is ≤5%.
- Risk factors that may result in renal failure include old age, HTN, elevated serum creatinine, and nephrotic and mixed nephritic–nephrotic syndrome at the onset of disease.

COMPLICATIONS
- Nephrotic/nephritic syndrome and renal failure
- HTN
- Hemorrhagic cystitis
- Ureteral obstruction
- Intestinal infarction, perforation, obstruction, stricture
- GI hemorrhage
- Intussusception
- Alveolar hemorrhage
- CNS complications, including cerebral hemorrhage and seizure
- Anterior uveitis
- Myocarditis
- Orchitis
- Testicular torsion

REFERENCES

ADDITIONAL READING

CODES
ICD10
D69.0 Allergic purpura

CLINICAL PEARLS
- HSP is a systemic small vessel vasculitis characterized by clinical tetrad of palpable purpura, abdominal pain, arthralgia, and renal dysfunction.
- The main form of treatment is supportive care, but oral corticosteroids may be beneficial if there appears to be severe renal involvement.
- In all patients with HSP, regardless of renal involvement at presentation, it is reasonable to check BP and urinalysis at weekly to monthly intervals for at least 6 months after diagnosis to monitor for developing renal dysfunction.
HEPARIN-INDUCED THROMBOCYTOPENIA
Tipsuda Junsanto-Bahri, MD

BASICS
DESCRIPTION
- A life-threatening complication of heparin use
  - Platelet count falls between 30% and 50% from baseline.
- Antibody-mediated prothrombotic disorder initiated by heparin administration
- Unlike other thrombocytopenias, heparin-induced thrombocytopenia (HIT) is an idiosyncratic reaction that results in thrombosis rather than bleeding.
- Two types: nonimmune heparin-associated thrombocytopenia (previously called HIT type I) and heparin-induced thrombocytopenia/thrombosis (HITT) (immune induced; previously called HIT type II)
  - Nonimmune heparin-associated thrombocytopenia (HIT): more common, onset 1 to 4 days after starting heparin, mild thrombocytopenia (>100,000/mm³), few complications
  - Immune HITT: less common, onset 5 to 14 days after primary exposure to heparin, thrombocytopenia often <100,000/mm³ but usually >20,000/mm³; high risk of thrombosis and mortality

EPIDEMIOLOGY
Incidence
- 0.1–5% of heparin-treated patients will experience thrombocytopenia, regardless of dose, schedule, or route of administration.
- 25–50% of these patients will develop HITT (1)(B).

ETIOLOGY AND PATHOPHYSIOLOGY
- Nonimmune heparin-associated thrombocytopenia: potentially a result of direct platelet membrane binding with heparin
- HITT: Heparin can cause an increase in the blood concentration of platelet factor 4 (PF4), a chemokine. PF4 will form a complex with heparin.
- Heparin/PF4 complex can, in turn, stimulate the production of specific antiheparin/PF4 complex antibodies. These antibodies cause platelet activation and a prothrombotic state. Ultimately, this hypercoagulable state leads to thromboembolic complications in many patients.
- Sources of heparin
- Heparin flushes (e.g., for arterial lines or heparin locks)
- Heparin-bonded catheters
- Unfractionated heparin (UFH)
- Low-molecular-weight heparin (LMWH) (enoxaparin, dalteparin)

RISK FACTORS
- Postsurgical > medical > obstetric
  - Post–cardiopulmonary bypass (CPB) is the most significant risk factor.
- Bovine UFH > porcine UFH > LMWH
Female > male
Heparin duration >5 days
Rare in pregnant females

GENERAL PREVENTION
- Inquire about recent heparin exposure and any history of HIT.
- Use of LMWH (vs. unfractionated), for a shorter duration, can reduce the risk of developing HIT.
- Properly document past HIT reactions in patient’s medical record. Develop a HIT recognition and treatment protocol.
- No form of heparin should be administered once the diagnosis of HIT is confirmed.

COMMONLY ASSOCIATED CONDITIONS
- Venous thrombosis: deep venous thrombosis (DVT), pulmonary embolism (PE), adrenal vein thrombosis with hemorrhagic infarction; seen more frequently among medical and postoperative orthopedic surgery patients
- Arterial thrombosis: myocardial infarction, stroke, mesenteric infarction, limb ischemia; seen more frequently among vascular and cardiac surgery patients
- Skin lesions (skin necrosis at site of injection)
- Acute systemic reactions

DIAGNOSIS
- Nonimmune heparin-associated thrombocytopenia (HIT): asymptomatic drop in platelet count
- HIT: thrombocytopenia or thrombosis with the presence of heparin-dependent antibodies
  - The foundation for diagnosis is based on both clinical and serologic findings.

HISTORY
- Duration of current heparin therapy
- Previous exposure to heparin, including heparin flushes and heparin-coated catheters
- In patients being treated with heparin for thrombosis, in which thrombosis recurs during therapy, consider HIT as a potential cause.
- Clinical scoring systems:
  - Pretest probability for HIT can be calculated using the commonly used “4 Ts” methodology:
    - Thrombocytopenia of new onset
    - Timing of thrombocytopenia (5 to 10 days after exposure)
    - Thrombosis of new onset
    - Thrombocytopenia by other causes is ruled out.
  - The HIT Expert Probability score is an effective pretest probability tool (2)[A].
- The post-CPB scoring system

PHYSICAL EXAM
- Signs of venous or arterial thrombosis
- Skin necrosis (begins with erythema, progresses to ecchymosis and necrosis)
- Ischemic changes (signs of limb, renal, splenic, mesenteric ischemia)
- Bleeding (less common)
**DIFFERENTIAL DIAGNOSIS**

Other potential causes of thrombocytopenia include (list is not all inclusive)
- Sepsis and other infections
- Drug reactions
- Autoimmune
- Transfusion reactions
- Physical destruction (e.g., during CPB)

**DIAGNOSTIC TESTS & INTERPRETATION**

- Serial platelet counts in patients receiving heparin who have a possible risk of HITT >1%:
  - Check platelets at baseline and then every 2 to 3 days from days 4 to 14 of heparin therapy:
    - Withhold platelet monitoring for patients receiving heparin with risk of HITT <1%.
- Confirmatory lab tests needed for a clinical diagnosis can be divided into two major categories:
  - Antigen assay to detect presence of anti-PF4 antibodies:
    - Enzyme-linked immunosorbent assay: up to 99% sensitive, poor specificity; has a high negative predictive value for HIT
  - Functional assay to detect evidence of platelet activation in the presence of heparin:
    - Serotonin release assay (SRA), gold standard for diagnosis: high specificity and high sensitivity
    - Heparin-induced platelet activation (HIPA): high specificity and low sensitivity
- Antigenic assay should be the initial test.
  - Either a functional assay or an antigenic assay alone may not be adequate for clinical diagnosis; their use in combination is usually recommended.
- The diagnostic interpretation of these laboratory tests must be made in the context of the clinical estimation of the pretest probability because HIT is a clinicopathologic syndrome. Patients may form heparin-dependent antibodies and still not develop HIT.

**TREATMENT**

Treatment is by prompt withdrawal of heparin and replacement with a suitable alternative anticoagulant. LMWH is NOT indicated in the treatment of HIT.

**GENERAL MEASURES**

- Discontinue all heparin products, including flushes and heparin-coated catheters.
- All patients with a diagnosis of HIT should receive alternative anticoagulation because they are of high thrombotic risk.
- Nonimmune heparin-associated thrombocytopenia generally resolves when heparin is stopped.

**ALERT**

- Platelet transfusions can increase thrombosis. Give platelet transfusions only if bleeding or during an invasive procedure with a high risk of bleeding.
- Warfarin should not be administered until platelet recovery. If warfarin has been administered, vitamin K should be given due to depletion of proteins S and C and increased risk for venous limb gangrene.
- Adverse reaction to heparin should be clearly documented in the patient’s medical record with
MEDICATION

Most patients require anticoagulation because of
– Preexisting thrombosis or
– Risk of thrombosis during 30 days after HIT diagnosis (consider anticoagulation for 30 days)

Dosing of anticoagulant depends on indication (prophylaxis vs. treatment):
– In cases with a clinically low suspicion/pretest probability of HIT and laboratory confirmation is pending, it may be appropriate to continue antithrombotic prophylaxis using nonheparin anticoagulants.
– In cases with high suspicion/pretest probability of HITT and laboratory confirmation is pending, it is appropriate to begin anticoagulation treatment with a nonheparin product (1)[B],(3)[A].

Direct thrombin inhibitors (DTIs) (argatroban and bivalirudin)
– Reduce relative risk of thrombosis by 30% and are associated with a 5–10% risk of bleeding.
– Can produce misleading elevation in international normalized ratio (INR) (most likely an in vitro reaction)
  o Argatroban > bivalirudin
– Argatroban
  o Currently approved for treatment of HITT or in patients undergoing percutaneous coronary intervention when heparin is contraindicated
  o Initial dose, 2 μg/kg/min by continuous IV infusion; decrease dose (0.5 to 1.2 μg/kg/min) for patients with reduced hepatic function or with critical illness.
  o Dose adjustments based to achieve activated partial thromboplastin time (aPTT) 1.5 to 3 times the baseline
  o Dose adjustment required for patients with hepatic dysfunction
– Bivalirudin
  o Off-label use for HIT, complicated by thrombosis
  o Reduced risk of bleeding in patients undergoing percutaneous artery interventions (PCIs) and other cardiac procedures
  o Initial dose of 0.15 to 0.20 mg/kg/hr; adjust aPTT 1.5 to 2.5 times the baseline.

Factor Xa inhibitors (3)[A]
– Reports of factor Xa treatment are theorized to be useful; however, minimal data support its efficacy for HIT, and an ideal dose has yet to be determined.
– Rivaroxaban has been frequently studied and provides evidence for HIT management
– Fondaparinux has not been recommended due to lack of evidence.

Warfarin transition
– Must anticoagulate with an immediate-acting agent before starting warfarin
– Begin warfarin after platelet count is >150,000/mm³.
– Discontinue other anticoagulant and continue only warfarin after INR is therapeutic (2 to 3).
for at least 5 days. This management differs from the normal heparin-to-warfarin transition in other conditions requiring anticoagulation (1)[A].

- **LMWH**
  - Although LMWH has a lower risk of initiating a HIT reaction, it should not be used when antibodies are already present, which cross-react with LMWH and induce thrombosis and thrombocytopenia.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Avoid heparin flushes.
- Avoid platelet transfusion.
- Clearly document reaction in all medical records to control the future use of heparin.
- HIT in pregnancy is rare. Safety of therapeutic agents has not been established but may be effective in the prevention of thrombotic complications.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- The transition period of anticoagulation with a DTI and warfarin in patients with HIT can be problematic.
- The INR while administering both a DTI and warfarin should be therapeutic (2 to 3) for at least 5 days before discontinuing the DTI.
- Warfarin therapy should not be commenced until the platelet count has stabilized within a normal range. Therapy should continue for a minimum of 3 months.
- DTIs can prolong INR; therefore, if INR is <4 while on both warfarin and a DTI, temporarily hold the DTI for 4 to 6 hours and recheck INR; this second INR will represent only the anticoagulant effect of warfarin.
- Monitor use of concurrent drugs with warfarin.

**Patient Monitoring**

- Serial platelet counts
- Monitor PTT or INR as determined by the anticoagulation agent.

**PATIENT EDUCATION**

Patient should inform all health care providers of any previous adverse reaction to heparin.

**PROGNOSIS**

- Thrombosis in HIT has 20–30% mortality, with additional morbidity from stroke and limb ischemia.
- Platelet counts normalize within weeks after stopping heparin.
- Risk of delayed thrombosis, especially in the first 30 days

**REFERENCES**

ADDITIONAL READING

CODES
ICD10
D75.82 Heparin induced thrombocytopenia (HIT)

CLINICAL PEARLS
- Heparin exposure through any preparation (including LMWH), any dose, or any route can cause HIT, a life-threatening condition that is associated with severe and extensive thromboembolism.
- LMWH, warfarin, and platelet transfusion are contraindicated in HIT, although LMWH is less likely to cause HIT. Once HIT is present, the antibodies will cross-react and continue to cause a HIT reaction.
- If a patient is suspected of HIT (with or without confirmatory testing), immediately discontinue all forms of heparin.
- Patients will require anticoagulation either because of preexisting thrombosis or the risk of thrombosis in first 30 days after HIT.
- A DTI should be used until a patient’s INR is therapeutic (2 to 3) on warfarin for at least 5 days.
- The key to avoiding sequelae from HIT is awareness, vigilance, and a high degree of suspicion.
HEPATIC ENCEPHALOPATHY
Walter M. Kim, MD, PhD

BASICS

DESCRIPTION
- Reversible altered mental and neuromotor functioning occurring in association with acute or chronic liver disease and/or portosystemic shunting
- The prominent features are confusion, impaired arousability, and a “flapping tremor” (asterixis).
- System(s) affected: gastrointestinal (GI); hepatic; nervous
- Synonym(s): portosystemic encephalopathy (PSE); hepatic coma; liver coma

EPIDEMIOLOGY
Predominant sex: male = female (reflects prevalence of underlying liver disease)

Prevalence
- May occur at any age
- Parallels the age predominance of fulminant liver disease: peaks in the 40s (cirrhosis peaks in the late 50s)
- Occurs in all cases of fulminant hepatic failure
- Overt hepatic encephalopathy (HE) occurs in 30–40% of cirrhotic patients.
- Present in ~50% of patients requiring liver transplantation

ETIOLOGY AND PATHOPHYSIOLOGY
- There is no defined pathophysiology for the development of HE. Three classifications have been proposed (1):
  - Type A: resulting from acute liver failure (ALF)
  - Type B: resulting from portosystemic bypass or shunting
  - Type C: resulting from cirrhosis
- Several metabolic factors implicated in HE based on the failure of the liver to detoxify noxious CNS agents (e.g., ammonia, mercaptan, fatty acids, lactate, manganese)
- Increased aromatic and reduced branched chain amino acids in blood may act as false neurotransmitters, possibly interacting with the γ-aminobutyric acid (GABA) receptor and causing clinical symptoms.
- HE presents most commonly in long-standing cirrhosis with spontaneous shunting of intestinal blood through collateral vessels or surgical portacaval shunts.
- Asterixis is the inability to maintain a particular posture due to metabolic encephalopathy. Abnormal diencephalic function leads to the characteristic liver flap noted when the arms and wrists are held in extension. Asterixis is also present in patients with uremia, barbiturate toxicity, and some cases of pulmonary disease. As such, asterixis is not pathognomonic for HE.

Genetics
- Unknown
- Conditions that predispose an individual to developing chronic liver disease such as cystic
fibrosis, $\alpha_1$-antitrypsin deficiency, hemochromatosis, and Wilson disease can contribute to the development of HE.

**RISK FACTORS**
In patients with underlying liver disease, precipitating factors include:
- Infection (overt or occult, including spontaneous bacterial peritonitis [SBP])
- GI hemorrhage
- Use of sedative (e.g., benzodiazepines) or opiate drugs
- Electrolyte disturbance ($Na^+$, $K^+$, $Mg^{2+}$ most common)
- Fluid abnormalities including from diuretic overdose
- Transjugular intrahepatic portosystemic shunt (TIPS—a radiologically inserted shunt to lower portal pressure)—elderly patients and those with worse liver function are at increased risk of developing HE following TIPS

**GENERAL PREVENTION**
- Recognize early signs and seek prompt treatment.
- Avoid nonessential medications, particularly opiates, benzodiazepines, and sedatives.
- Consider lactulose therapy as secondary prophylaxis for recurrence of HE (2)[B].

**COMMONLY ASSOCIATED CONDITIONS**
- May occur as a complication of acute fatty liver of pregnancy
- Occurs rarely in patients with a portacaval shunt accompanied by normal liver function

**DIAGNOSIS**

**HISTORY**
- Preexisting liver disease
- Confusion; altered mental status
- Impaired arousability
- Constipation

**PHYSICAL EXAM**
- Age 10 to 60 years
  - Five grades of confusion and degree of obtundation (West Haven classification) (1):
    - Minimal: psychometric or neuropsychological alterations without mental status changes
    - Grade I: lack of awareness, anxiety, shortened attention span, impaired arithmetic, altered sleep rhythm
    - Grade II: asterixis, lethargy, disorientation to time, personality change, inappropriate behavior
    - Grade III: somnolence to stupor, confusion, gross disorientation, bizarre behavior
    - Grade IV: coma
  - Prominent signs of underlying liver disease (50%); jaundice is most common, ascites is second most common.
  - GI bleeding with hematemesis or melena (20%)
  - Systemic infection, urinary tract infection, or pulmonary infection (20%)
- Age >60 years
  - Signs of underlying liver disease diminish (25%).
Confusion more prominent
Precipitating GI hemorrhage or infection is less often identified.
Progression is slower.

- Age <10 years
  - Signs of underlying liver disease are prominent; fulminant hepatic failure or advanced cirrhosis
  - Progression is very rapid, often over hours.
  - Wilson disease can imitate HE.

- Vital signs:
  - Bradycardia
  - Increased blood pressure suggestive of increased intracranial pressure
- Jaundice, ascites, other correlates of liver disease
- CNS exam: Assess short-term memory and presence of asterixis (“liver flap”—a flapping of the wrist when arms and wrists are extended).
- Pupillary reaction regresses from normal to sluggish and then absent with worsening HE.

**DIFFERENTIAL DIAGNOSIS**

- Metabolic encephalopathy related to anoxia, hypoglycemia, hypokalemia, hypo- or hypercalcemia, or uremia
- Head trauma, concussion, subdural hematoma
- Transient ischemic attack (TIA), ischemic stroke
- Increased intracranial pressure (ICP), intracranial hemorrhage (ICH)
- Alcohol intoxication
- Alcohol withdrawal syndrome
- Confusion due to medications or illicit drugs
- Meningitis, encephalitis
- Wilson disease
- Reye syndrome
- Wernicke-Korsakoff syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

- Clinical findings diagnostic in 80% of cases
- Response to treatment often confirms the diagnosis.
- Electroencephalogram (limited utility): symmetric slowing of basic (α) rhythm (also common with other metabolic encephalopathies)
- Visual evoked potential: specific in grades II to IV
- Number connection test (NCT), line drawing test, critical flicker frequency (CFF) test, digit symbol test (DST), continuous reaction time (CRT) test, inhibitory control test (ICT), repeatable battery for the assessment of neuropsychological status (RBANS), and other psychometric tests may be used to assess minimal HE.

**Initial Tests (lab, imaging)**

- Serum ammonia level is elevated in 90% of patients with HE, however is not diagnostic nor correlative with disease severity; levels are affected by infusion of amino acid solutions, opiate administration (constipation), uremia, tissue breakdown, burns, trauma, or infection
- Liver function tests, including aspartate aminotransferase (AST), alanine aminotransferase (ALT), and serum albumin
Prothrombin time (PT) and international normalized ratio (INR) often elevated
- Complete blood count: anemia and leukocytosis
- Complete metabolic profile to identify hypokalemia, hyperbilirubinemia, altered calcium concentration, hypomagnesemia, and hypoglycemia
- Blood urea nitrogen: Creatinine >20 mg/dL suggests dehydration or GI bleeding.
- Diagnostic paracentesis to rule out SBP
- Blood, urine, sputum, and ascitic fluid cultures to identify infection, as clinically indicated
- Consider arterial blood gas measurement
- Toxicology screen
- Head CT to identify frontal cortical atrophy and/or edema
- MRI may demonstrate increased T1 signal within the globus pallidus.

Test Interpretation
- Brain edema is seen in 100% of fatal cases.
- Glial hypertrophy in chronic encephalopathy

🔥 TREATMENT

GENERAL MEASURES
- Identify and treat precipitating causes: electrolyte imbalance, GI bleeding, infection.
- Avoid sedatives, benzodiazepines, opiates, diphenoxylate, and atropine.
- Grade I or higher: Ensure adequate fluid and caloric ≥1,000 kcal (4.19 MJ) intake; avoid hypoglycemia.
- Consider lactulose enema for patients without diarrhea.
- If clumsiness and poor judgment are prominent, institute fall precautions.

MEDICATION

First Line
- Lactulose syrup (nonabsorbable disaccharide with laxative action that decreases colonic transit time and bacterial digestion that acidifies the colon to promote ammonia excretion): 30 to 45 mL PO up to every hour for goal of 3 to 6 bowel movements per day. Decrease to 15 to 30 mL BID when ≥3 bowel movements per day (3)[A].
- Lactulose enema (for patients who cannot tolerate oral lactulose or have suspected ileus): 300 mL lactulose plus 700 mL tap water, retained for 1 hour
- If worsening occurs acutely or there is no improvement in 2 days, add antibiotics:
  - Rifaximin: 400 mg PO TID or 550 mg PO BID (nonabsorbable antibiotic); highly effective in reversing minimal HE (4)[B]

Contraindications:
- Total ileus
- Hypersensitivity reaction

Precautions:
- Hypokalemia
- Electrolyte imbalance
- Dehydration and renal failure

Second Line
- Neomycin: 1 to 2 g/day PO divided q6–8h, if renal function is within normal limits
- Polyethylene glycol may be effective as an alternative to lactulose in management of acute HE (5)[B].
- Metronidazole is an alternative antibiotic.
- Flumazenil may be of benefit in select patients.

**ISSUES FOR REFERRAL**
Refer early to experienced transplant center.

**SURGERY/OTHER PROCEDURES**
- Artificial liver perfusion devices are useful in fulminant hepatic failure as a bridge to transplantation.
- Consider liver transplant in grade II to IV HE.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Probiotics and prebiotics have been associated with improvement of HE through modulation of gut flora (1)[C].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Monitor clinical status closely in grades I and II when diagnosis is clear and watch for progression.
- Evaluate patients with grades II to IV HE in fulminant hepatic failure for liver transplantation.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Activity as tolerated once resolved

**Patient Monitoring**
- Assessment of asterixis and using the trail-making test (ask patient to connect-the-dots according to numbers) helps to monitor HE patients. Periodic evaluation helps determine maintenance treatment and diet. Test daily at first and then at each visit when changes in drugs and diet are made.
- See patients biweekly if there are changes on the trail-making test.
- Stable patients should be seen monthly.
- NCT or line drawing test at each office visit can also help with patient monitoring.
- In cirrhosis, evaluate for transplantation and periodically monitor Model for End-Stage Liver Disease (MELD) score.

**DIET**
- Regular protein diet (1.2 to 1.5 g/kg/day); vegetable protein diets are better tolerated than animal protein diets in patients with advanced cirrhosis; special IV/enteral formulations with increased branched chain amino acids are available.
- Grades III to IV patients need parenteral nutrition or jejunal feeds.

**PATIENT EDUCATION**
American Association for the Study of Liver Diseases, 1729 King Street, Suite 200, Alexandria, VA 22314; 703-299-9766; www.aasld.org
PROGNOSIS

- With appropriate treatment, acute HE often resolves.
- Chronic liver disease
  - HE recurs.
  - With each recurrence, HE is more difficult to treat—the degree of improvement with treatment is reduced and the mortality rate approaches 80%.

COMPLICATIONS

- Recurrence
- With many recurrences, permanent basal ganglion injury (non-Wilsonian hepatolenticular degeneration)
- Hepatorenal syndrome

CODES

ICD-10
ICD10

- K72.90 Hepatic failure, unspecified without coma
- K72.91 Hepatic failure, unspecified with coma

CLINICAL PEARLS

- HE includes a spectrum of neuropsychiatric findings that occur in patients with significant alterations in hepatic function.
- Lactulose is a cornerstone of therapy for HE.
- Asterixis (“liver flap”) is the classic physical finding associated with HE.
HEPATITIS A
Marie L. Borum, MD, EdD, MPH, MACP, FACG, AGAF ● Vinay S. Rao, BA

BASICS

DESCRIPTION
Hepatitis A infections are caused by the hepatitis A virus (HAV), a member of the Hepatovirus genus. This virus is one of the world’s most common infections and primarily involves the liver. HAV is one of several types of hepatitis viruses that can lead to liver injury. However, compared to the other hepatitis viruses, HAV has distinct features that set it apart.

EPIDEMIOLOGY

Incidence
- 1.4 million cases globally each year
- Since routine use of the hepatitis A vaccine (1995), the incidence of HAV has decreased by 95%.
- Approximately 4,000 HAV infections occurred in 2016.
- Between 2016 and 2018, reports of hepatitis A infections increased by 294% from 2013 to 2015.
- No difference in infection rates based on sex
- As many as 1/2 of current HAV infections in the United States are acquired during travel to endemic countries.
- Incubation period averages about 28 days (range 15–50 days)

Prevalence
Serologic evidence of prior HAV infection is present in approximately 1/3 of the U.S. population. Anti-HAV prevalence relates to age, ranging from 9% in children ages 6 to 11 years to 75% of those >70 years.

Pediatric Considerations
- Often, milder or asymptomatic in children; severity increases with age.
- Infections asymptomatic in 70% of children <6 years.
- <50% of 13 to 17 year olds in the United States are vaccinated.

Pregnancy Considerations
- Increased risk of complications including preterm labor and premature rupture of membranes.
- Vertical transmission has been reported; fecal–oral transmission during birth is possible.
- Breastfeeding is not contraindicated.

ETIOLOGY AND PATHOPHYSIOLOGY
- HAV is a single-stranded linear RNA enterovirus of the Picornaviridae family.
- Infection is limited to hepatocytes and macrophages.
- HAV is excreted into the bile and then stool.
- Primary transmission is fecal–oral.
- Can also transmit through sexual intercourse (particularly anal–oral contact) and intravenous
drug use.

- Humans are the only natural host.
- Incubation is 2 to 6 weeks (mean 4 weeks).
- Greatest infectivity is the 2 weeks before and 1 week after onset of clinical illness.
- Infection occurs primarily after consuming food or water contaminated with HAV or via direct contact.
- Virus is stable in water and on surfaces but is easily killed with high heat or cleaning agents.
- Shellfish (clams and oysters) may be contaminated if harvested from waters contaminated with HAV.
- HAV is not a chronic disease but can last for several months.

**Genetics**

Autoimmune hepatitis is rarely associated with human leukocyte antigen class II DR3 and DR4 after active infection with HAV.

**RISK FACTORS**

- **Person-to-person contact:**
  - Intimate exposure, particularly among men who have sex with men
  - Residential institutional transmission
  - Transmission among military personnel
  - Employment in health care
- **Contaminated food or water contact:**
  - Travel to developing countries accounts for >50% of cases in North America and Europe
  - Consumption of raw/undercooked shellfish, vegetables, or other foods
  - Consumption of improperly handled food
- **Other modes of transmission:**
  - Injection of illicit drugs
  - Blood exposure or transfusion (rare)
- No identifiable risk factor in 50%

**GENERAL PREVENTION**

- Proper sanitation and personal hygiene (hand washing), especially for food handlers, health care, and daycare workers.
- Active immunization through HAV vaccines:
  - Havrix and Vaqta—inactive vaccine
  - Twinrix—combination HAV and HBV
- Vaccine thought to provide protection for 25 years or more.
- **Vaccine is recommended for (1)[C],(2)[A]:**
  - All children aged 12 to 23 months, with catch-up administration until 18 years old
  - All travelers to countries with high endemic rate of hepatitis A (parts of Africa and Asia)
  - Men who have sex with men
  - Illicit IV drug users
  - Those with chronic liver disease (including pre– and post–liver transplant patients)
  - Individuals with a clotting factor disorder
  - Household members and close contacts of children adopted from countries with a high HAV prevalence (prior to arrival)
  - Anyone exposed during an outbreak
- Routine vaccination is no longer routinely recommended for food service, child care, or health care workers (1)[C].
- HIV-infected patients who are negative for HAV IgG should receive the HAV vaccine series, preferably early in course of HIV infection (1)[C].
  - If CD4 count is <200 cells/mm\(^3\) or the patient has symptomatic HIV disease, defer vaccination until several months after initiation of antiretroviral (ARV) therapy to maximize antibody response.
  - Hepatitis A vaccine can be given to immunocompromised patients with CD4 count >200 cells/mm\(^3\).
  - Hepatitis A vaccine is recommended for pregnant women with additional medical conditions (higher risk for HAV infection).
- HAV is not killed by freezing.
- HAV is killed by:
  - Heating to 185°F for 60 seconds
  - Chlorine
  - Iodine

**COMMONLY ASSOCIATED CONDITIONS**
HAV can sometimes be associated with more rare extrahepatic manifestations such as:
- Glomerulonephritis
- Cryoglobulinemia
- Optic neuritis
- Myocarditis
- Thrombocytopenia, aplastic anemia, or red cell aplasia
- Leukocytoclastic vasculitis

**DIAGNOSIS**

**HISTORY**
- Onset is often abrupt. Common initial symptoms include nausea, emesis and diarrhea, and headache.
- Symptom severity increases with age.
- Pediatric cases (<6 years) frequently asymptomatic
- Other presenting historical findings:
  - Fever, malaise, fatigue, myalgias, anorexia, joint pain
  - Dark urine (bilirubinuria)
  - Right upper abdominal pain
  - Pruritus (can suggest cholestasis)

**PHYSICAL EXAM**
- Fever (variable)
- Jaundice and icterus present in >70% of adults and older children
- Hepatomegaly is common (>80% of cases); splenomegaly is less common.
- Right upper quadrant abdominal tenderness
- Rare: lymphadenopathy (cervical), arthritis, or rash
- Asterixis suggests acute hepatic failure.
DIFFERENTIAL DIAGNOSIS

- Hepatitis B, C, D, E. Not clinically distinguishable from other forms of viral hepatitis; diagnosis may be suspected with typical symptoms during an outbreak.
- HIV infection
- Drug-induced hepatitis; toxin-induced hepatitis
- Alcoholic hepatitis; autoimmune hepatitis
- Hemochromatosis (adults) or Wilson disease
- Malarial infection
- Adenovirus infection
- Epstein-Barr virus (EBV), cytomegalovirus (CMV), herpes simplex virus, yellow fever
- Primary or secondary hepatic malignancy
- Ischemic hepatitis or Budd-Chiari syndrome
- Nonhepatobiliary disease (elevated aspartate aminotransferase/alanine aminotransferase [AST/ALT]): celiac disease, congestive heart failure, thyroid disease
- Bacterial infections (Q fever, leptospirosis, syphilis, Rocky Mountain spotted fever)
- Parasites (liver flukes or toxocariasis)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Anti-HAV IgM: positive at time of onset of symptoms sensitivity and specificity >95%; primary test used to diagnose acute infection
- Anti-HAV IgG: appears soon after IgM and generally persists from years to lifetime
- AST/ALT elevated ~500 to 5,000: ALT usually > AST
- Alkaline phosphatase: mildly elevated
- Bilirubin: Conjugated and unconjugated fractions usually increased. Bilirubin rises typically following rise in ALT/AST, consistent with hepatocellular injury pattern.
- Prothrombin time and partial thromboplastin time usually remain normal or near normal.
  - Significant rises should raise concern for acute hepatic failure or coexisting chronic liver disease.
- Complete blood count: mild leukocytosis; aplasia and pancytopenia
  - Thrombocytopenia may predict illness severity.
  - Autoimmune hemolytic anemia (rare)
- Albumin, electrolytes, and glucose to evaluate for hepatic and renal function (rare renal failure)
- Urinalysis (not clinically necessary): bilirubinuria
- Consider ultrasound (US) to rule out biliary obstruction only if lab pattern is cholestatic.

Follow-Up Tests & Special Considerations

- Illness usually resolves within 4 weeks of symptom onset.
- Repeat labs are not indicated unless symptoms persist or new symptoms develop.

Diagnostic Procedures/Other

- Liver biopsy is usually not necessary.
- US can evaluate other causes (e.g., thrombosis or concurrent cirrhosis).

Test Interpretation

- Positive serum markers in hepatitis A
– Acute disease: anti-HAV IgM only
– Recent disease (last 6 months): anti-HAV IgM and IgG positive
– Previous disease or prior vaccination: anti-HAV IgM negative and IgG positive
  ● If liver biopsy obtained, shows portal inflammation; immunofluorescent stains for HAV antigen positive

**TREATMENT**

**GENERAL MEASURES**
- Maintain appropriate nutrition/hydration.
- Avoid alcohol.
- Universal precautions to prevent spread
- Monitor coagulation defects, fluid, electrolytes, acid–base imbalance, hypoglycemia, and renal function.
- Report cases to local public health department.
- Laboratory evaluation including coagulation factors to rule out hepatic failure
- Referral to liver transplant center for fulminant failure (rare)

**MEDICATION**
- Preexposure vaccination per recommended guidelines. Both hepatitis A vaccines in the United States (Havrix, Vaqta) require 2 doses at least 6 months apart.
  - The Advisory Committee on Immunization Practices recommends administering the first dose as soon as possible in travelers to endemic areas (1)[C].
    - For healthy individuals <40 years, vaccinate up to the day or departure.
    - Give immunoglobulin (0.02 mL/kg) to those >40 years, chronic medical conditions, or immunosuppression if <2 weeks from planned departure.
    - For infants between 6–11 months vaccine dose does not provide long-term protection; infant will require vaccine series at 12 months
- Give postexposure prophylaxis to persons who have not previously received HAV vaccine within 2 weeks of exposure to HAV (3)[A],(4)[C].
  - Administer hepatitis A vaccine series to healthy persons between the ages of 1 and 40 years (5)[A].
  - Administer immunoglobulin (0.02 mL/kg) to persons <1 or >40 years of age or to patients with significant comorbidities (immunosuppression, liver disease) who are at risk for poor immune response (3)[A],(4)[C].
- Use immunoglobulin for passive preexposure prophylaxis if not eligible for the vaccine (3)[A],(4)[C].
  - 0.02 mL/kg provides 1 to 2 months of coverage; 0.06 mL/kg provides 3 to 5 months of coverage.
  - Long-term prophylaxis should be with 0.06 mL/kg every 5 months for sustained risk (e.g., travelers).
  - Infants age <6 months and travelers allergic to vaccine components should receive 1 dose of 0.1 mL/kg.
  - Use immunoglobulin alone in children <1 year and unvaccinated pregnant women who will be traveling.
  - Do not give immunoglobulin with the measles, mumps, and rubella or varicella vaccines.
First Line
- No antiviral medications indicated; spontaneous resolution occurs in nearly 99% of patients.
- Caution with acetaminophen; if used, limit to 2 g/day or less.
- Avoid hepatotoxic agents.

Second Line
- Antiemetics (e.g., ondansetron)
- IV fluids
- Pruritus: diphenhydramine 50 mg PO IM q6h; consider cholestyramine 4 g BID if cholestasis.

ISSUES FOR REFERRAL
- Dictated by severity of illness
- Hepatic failure, refer to a high-volume liver transplant program

SURGERY/OTHER PROCEDURES
Liver transplant in fulminant hepatic failure—only rare indications

COMPLEMENTARY & ALTERNATIVE MEDICINE
Avoid potentially hepatotoxic botanicals including barberry, comfrey, golden ragwort, groundsel, huang qin, kava kava, pennyroyal, sassafras, senna, valerian, wall germander, and wood sage.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Treatment is usually outpatient unless signs of liver failure; dictated by severity of illness.
- Treat dehydration and electrolyte imbalances.
- Enteric isolation. Private rooms, gowns, and masks are not necessary.
- Frequent hand washing. Use gloves when handling potentially contaminated material.
- 1:100 bleach dilution can be used to clean surfaces.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Return to work/school 10 to 14 days after onset of symptoms with diligence to hygiene (patients remain infectious for up to 4 weeks from symptom onset).

Patient Monitoring
Monitor:
- Coagulation defects
- Fluid and electrolytes
- Acid–base imbalance
- Hypoglycemia
- Renal function

DIET
- Adequate balanced nutrition
- Avoid alcohol

PATIENT EDUCATION
• Segregate food handlers with HAV
• HAV immunity persists after infection
• CDC hepatitis A FAQs link: https://www.cdc.gov/hepatitis/hav/afaq.htm

PROGNOSIS
• Excellent; mortality is 0.3%
• Risk increased with underlying chronic liver disease and in the elderly (1.8% mortality age >50 years)

COMPLICATIONS
• Coagulopathy, encephalopathy, and renal failure
• Relapsing HAV: usually milder than the initial case
• Positive anti-HAV IgM; total duration typically <9 months
• Prolonged cholestasis: characterized by protracted periods of jaundice and pruritus (>3 months); resolves with supportive care only
• Autoimmune hepatitis: can be seen after HAV infection; however, responds well to steroids
• Hepatic failure is rare (1–2%)
• Postviral encephalitis, Guillain-Barré syndrome, pancreatitis, aplastic or hemolytic anemia, agranulocytosis, thrombocytopenic purpura, pancytopenia, arthritis, vasculitis, and cryoglobulinemia (all rare)

CODiES

ICD10

B15.9 Hepatitis A without hepatic coma

CLINICAL PEARLS

- HAV vaccine is indicated for all children, travelers (particularly to endemic areas), those at elevated risk of disease, and patients with liver impairment.
- Check HAV IgG in all HIV-positive patients; provide HAV vaccine if results are negative.
- HAV disease severity directly correlates with age; children are often asymptomatic.
- Treatment of acute HAV is supportive.
- Eligible patients should receive postexposure prophylaxis within 14 days of exposure.
HEPATITIS B
Navpreet K. Singh, MD ● Jason Chao, MD, MS

BASICS

DESCRIPTION
Systemic viral infection associated with acute and chronic liver disease and hepatocellular carcinoma (HCC)

EPIDEMIOLOGY

Incidence
- Predominant age: can infect patients of all ages
- Predominant sex: fulminant hepatitis B virus (HBV): male > female (2:1)
- In the United States, ~3,200 cases of acute HBV in 2016
- African Americans have the highest rate of acute HBV infection in the United States.
- Overall rate of new infections is down 82% since 1991 (due to national immunization strategy). There has been a slight increase in new infections since 2014 (associated with increased IV drug use).
- Vaccine coverage for the birth dose ~72% in United States

Prevalence
- In the United States, 800,000 to 1.4 million with chronic HBV
- Asia and the Pacific Islands have the largest populations at risk for HBV.
- Chronic HBV worldwide: 350 to 400 million persons
  - 1 million deaths annually
    - Second most important carcinogen (behind tobacco)
    - Of chronic carriers with active disease, 25% die due to complications of cirrhosis or HCC.
    - Of chronic carriers, 75% are Asian.

ETIOLOGY AND PATHOPHYSIOLOGY
HBV is a DNA virus of the Hepadnaviridae family; highly infectious via blood and secretions

Genetics
Family history of HBV and/or HCC

RISK FACTORS
- Screen the following high-risk groups for HBV with HBsAg/sAb. Vaccinate if seronegative
  (1)[A]:
  - Persons born in endemic areas (45% of world)
  - Hemodialysis patients
  - IV drug users (IVDUs), past or present
  - Men who have sex with men (MSM)
  - HIV- and hepatitis C virus (HCV)-positive patients
  - Household members of HBsAg carriers
  - Sexual contacts of HBsAg carriers
  - Inmates of correctional facilities
– Patients with chronically elevated aspartate aminotransferase/alanine aminotransferase (AST/ALT) levels

Additional risk factors:
– Needle stick/occupational exposure
– Recipients of blood/products; organ transplant recipients
– Intranasal drug use
– Body piercing/tattoos
– Survivors of sexual assault

Pediatric Considerations
● Shorter acute course; fewer complications
● 90% of vertical/perinatal infections become chronic.

Pregnancy Considerations
● Screen all prenatal patients for HBsAg (1)[A].
● If HBsAg (+), obtain HBV DNA.
● Consider treating patients with high viral load at 28 weeks or history of previous HBV (+) infant with oral nucleos(t)ide medication beginning at 32 weeks to reduce perinatal transmission (2)[C].
● Infants born to HBV-infected mothers require hepatitis B immune globulin (HBIg) (0.5 mL) and HBV vaccine within 12 hours of birth.
● Breastfeeding is safe if HBIg and HBV vaccines are administered and the areolar complex is without fissures or open sores. Oral nucleos(t)ide medications are not recommended during lactation.
● HIV coinfection increases risk of vertical transmission.
● Continue medications if pregnancy occurs while on an oral antiviral therapy to prevent acute flare.

GENERAL PREVENTION
Most effective: HBV vaccination series (3 doses)
● Vaccinate
  – All infants at birth and during well-child care visits
  – All at-risk patients (see “Risk Factors”)
  – Health care and public safety workers
  – Sexual contacts of HBsAg carriers
  – Household contacts of HBsAg carriers
● Proper hygiene/sanitation by health care workers, IVDUs, and tattoo/piercing artists
  – Barrier precautions, needle disposal, sterilize equipment, cover open cuts
● Do not share personal items exposed to blood (e.g., nail clipper, razor, toothbrush).
● Safe sexual practices (condoms)
● HBsAg carriers cannot donate blood or tissue.
● Postexposure (e.g., needle stick): HBIg 0.06 mL/kg in <24 hours in addition to vaccination

COMMONLY ASSOCIATED CONDITIONS
HIV, hepatitis C coinfection
DIAGNOSIS

HISTORY
- Exposure: detailed family and social history
- Acute HBV
  - Fever, malaise, fatigue, arthralgias, myalgias
  - Anorexia, nausea, vomiting
  - Jaundice, scleral icterus
  - Dark urine, pale stools
  - Right upper quadrant (RUQ) abdominal pain
- Chronic HBV: typically asymptomatic

PHYSICAL EXAM
Acute disease: ill; jaundice/scleral icterus; RUQ tenderness; hepatomegaly

DIFFERENTIAL DIAGNOSIS
- Epstein-Barr virus (EBV); cytomegalovirus (CMV); hepatitis A, C, or E
- Drug-induced, alcoholic, or autoimmune hepatitis
- Wilson disease or rheumatologic/immunologic disorders

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- AST/ALT: markedly elevated in acute HBV (particularly ALT-hundreds to several thousand IU/mL). Transaminases may be normal or mildly elevated in chronic HBV:
  - Transaminases elevate before bilirubin.
- Bilirubin (conjugated/unconjugated): normal to markedly elevated in acute HBV
  - Last test to normalize as acute infection resolves
- Alkaline phosphatase: mild elevation
- HBcAb IgM may be the only early finding (“window period,” before HBsAg turns positive).
- For acute hepatitis:
  - PT, albumin, electrolytes, glucose, and complete blood count (CBC)
  - If severe acute HBV, check for superinfection with hepatitis D (HDV Ag and HDV Ab).
  - Hepatitis B serologic markers
- Hepatitis B e-antigen (HBeAg+) indicates high replication/infectivity; confirmed with high HBV DNA (≥10^5 copies/mL); benefit from medical therapy
- HBV precore mutants have undetectable HBeAg despite active viral replication (confirm with HBV DNA level) as well as antibody to e-antigen (HBeAb+).
- Screen for HDV, HIV, HCV, and immunity to hepatitis A virus (HAV Ab total/IgG).
- Ultrasound to document ascites, organomegaly, signs of portal hypertension, hepatic or portal obstruction, and to screen for HCC
- Contrast CT or MRI if ultrasound is abnormal or if α-fetoprotein (AFP) is elevated

Follow-Up Tests & Special Considerations
HBsAg+ persistence >6 months defines chronic HBV:
- Measure HBV DNA level and ALT every 3 to 6 months.
- If age >40 years and ALT borderline or mildly elevated, consider liver biopsy.
- Measure baseline AFP.
Follow HBeAg for elimination (every 6 to 12 months).
Lifetime monitoring for progression, need for treatment, and screening for HCC

**Diagnostic Procedures/Other**
- Liver biopsy
- Noninvasive tests (Hepascore, FibroTest) or measurement of elastography (FibroScan) to assess for hepatic fibrosis

**Test Interpretation**
Liver biopsy in chronic HBV may show interface hepatitis and inflammation, necrosis, cholestasis, fibrosis, cirrhosis, or chronic active hepatitis.

---

**TREATMENT**

**GENERAL MEASURES**
- Vaccinate for HAV if seronegative.
- Monitor CBC, coagulation, electrolytes, glucose, renal function, and phosphate.
- Monitor ALT and HBV DNA; increased ALT and reduced DNA implies response to therapy.
- Screen for HCC if HBsAg+.

**MEDICATION**

**First Line**
- Acute HBV
  - Supportive care; spontaneously resolves in 95% of immunocompetent adults
  - Antiviral therapy not indicated except for fulminant liver failure or immunosuppressed

</tbody>
</table>

**Chronic HBV**: Treatment is based on HBeAg status:
- FDA-approved drugs: lamivudine 100 mg, adefovir 10 mg, entecavir 0.5 to 1.0 mg, telbivudine 600 mg, or tenofovir 300 mg, all given PO every day (dose based on renal function); pegylated interferon (peg-IFN) α2a, α2b SC weekly (3)[A]
- Entecavir, tenofovir, and peg-IFN are preferred first-line agents (3)[A].
- Extended oral regimens are indicated (3)[A]:
  - If HBeAg+, treat 6 to 12 months postdisappearance of HBeAg and gain of HBeAb, and monitor after cessation.
  - If HBeAg-, treat indefinitely or until HBsAg clearance and HBsAb development.
- Change/add drug based on resistance:
  - Confirm medication adherence prior to assuming drug resistance.
Adherence to therapy lowers rate of resistance.

Adjust dosing for renal function.

Peg-IFN preferred to standard interferon:
- Weekly peg-IFN (Pegasys) injections for 48 weeks
- Most efficacious for genotype A
- Contraindicated if decompensated cirrhosis

Goals of therapy: undetectable HBV DNA, normal ALT, loss of HBeAg, gain of HBeAb; loss of HBsAg and gain of HBsAb

Precautions:
- Oral drugs: renal insufficiency
- Peg-IFN: coagulopathy, myelosuppression, depression/suicidal ideation

**ISSUES FOR REFERRAL**

- Refer all persistent HBsAg+ patients for potential antiviral therapy.
- Immediate referral for liver transplant if fulminant acute hepatitis, end-stage liver disease, or HCC

### Chronic Hepatitis B Therapy

</table>

*ALT elevated if >2 X ULN; ULN for male = 30 IU/mL and for female = 19 IU/mL.

**SURGERY/OTHER PROCEDURES**

Liver transplantation, operative resection, radiofrequency ablation for HCC

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Worsening course (marked increase in bilirubin, transaminases, or symptoms)
- Hepatic failure (high PT, encephalopathy)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Serial ALT and HBV DNA:
- High ALT + low HBV DNA associated with favorable response to therapy

CBC for white blood cell and platelets if on interferon therapy

Monitor HBV DNA q3–6mo during therapy:
- Undetectable DNA at week 24 of oral drug therapy associated with low resistance at year 2

Monitor for complications (ascites, encephalopathy; variceal bleed) in cirrhosis.

Vaccinate household contacts and sexual partners.

Ultrasound q6–12mo to screen for HCC starting at age 40 years in men and age 50 years in women (3)[B]

Diet
Avoid alcohol.

Patient Education
- Acute HBV
  - Review transmission precautions.
- Chronic HBV
  - Alcohol and tobacco use accelerate progression.
  - Emphasize medication compliance to prevent flare.

Complications
- Hepatic necrosis; cirrhosis; hepatic failure
- HCC (all chronic HBV patients are at risk)
- Severe flare of chronic HBV with corticosteroids and other immunosuppressants: Avoid if possible.
- Reactivation of infection if immunosuppressed. Premedicate prophylactically if HBsAg+ or if HBcAb+ and receiving systemic chemotherapy (1)[A].

CODES

ICD10
- B19.10 Unspecified viral hepatitis B without hepatic coma
- B16.9 Acute hepatitis B w/o delta-agent and without hepatic coma
- B18.1 Chronic viral hepatitis B without delta-agent

CLINICAL PEARLS
- Screen all patients born in countries with endemic disease for HBV infection using HBsAg.
- Patients with chronic HBV need lifetime monitoring for disease progression and HCC.
- HBV is the second most common worldwide carcinogen (behind tobacco).
HEPATITIS C
Jennifer L. Bauer, MD • Christopher Lin-Brande, MD

BASICS

DESCRIPTION
Hepatitis C virus (HCV) is a systemic viral infection (acute and chronic) primarily involving liver.

EPIDEMIOLOGY

- Highest incidence between ages 20 and 39 years; highest prevalence between 40 and 59 years of age
- Males and non-Hispanic blacks (1)
- IV drug use accounts for 70% of new HCV infections.

Geriatric Considerations
Patients >60 years are less responsive to therapy; important to initiate treatment early

Pregnancy Considerations

- Routine HCV testing is not indicated.
- Vertical transmission 6/100 births; risk doubles with HIV coinfection.
- Breastfeeding is safe if no cracks or fissures.

Pediatric Considerations

- Prevalence: 0.3%
- Test children born to HCV-positive mothers with HCV Ab at 18 months or HCV RNA at 1 to 2 months.
- More likely to clear spontaneously; slower rate of progression

Incidence
Incidence of acute HCV infection increased nearly 3-fold from 2010 to 2015. In 2015, there were 2,436 cases of acute HCV reported to the CDC, with an estimated 33,900 total new cases in the United States.

Prevalence

- Approximately 3.5 million persons in the United States have chronic HCV (Ab+).
- Prevalence highest if born 1945 to 1965 (2.6%) (1)
- HCV-related deaths are more common than HIV-related deaths.
- HCV is the most common cause of chronic liver disease and transplantation in the United States.
- Six known genotypes (GT) with 50 subtypes. GT 1 is predominant form in the United States (75%). GT predicts response to treatment.

ETIOLOGY AND PATHOPHYSIOLOGY
Single-stranded RNA virus of Flaviviridae family

RISK FACTORS
• Exposure risks
  – Chronic hemodialysis
  – Blood/blood product transfusion or organ transplantation before July 1992
  – Hemophilia treatment before 1987
  – Household or health care–related exposure to HCV-infected body fluids (1.8% risk)
  – Children born to HCV-positive mothers

• Risk behaviors and/or medical conditions
  – Prior history of injection drug use
  – Intranasal illicit drug use
  – History of incarceration
  – Tattooing in unregulated settings
  – High-risk sexual behaviors
  – HIV and hepatitis B infection

GENERAL PREVENTION
• Primary prevention
  – Do not share razors/toothbrushes/nail clippers.
  – Use and dispose needles properly through harm reduction programs.
  – Practice safe sex.
  – Cover cuts and sores.

• Secondary prevention
  – No vaccine or postexposure prophylaxis available
  – Substance abuse treatment
  – Reinforce use of barrier contraception for HIV-seropositive coinfected with HCV.
  – Assess for degree of liver fibrosis/cirrhosis.

COMMONLY ASSOCIATED CONDITIONS
Diabetes, metabolic syndrome, iron overload, depression, substance abuse/recovery, autoimmune and hematologic disease; cutaneous manifestations (necrotizing vasculitis, mixed cryoglobulinemia, porphyria cutanea tarda, lichen planus, erythema multiforme, erythema nodosum), HIV, and hepatitis B coinfection

DIAGNOSIS

HISTORY
• Determine exposure risk: detailed social history, including alcohol and IV drug use, psychiatric and medical comorbidities, and coinfections.
• Chronic HCV: Most cases are mildly symptomatic (nonspecific fatigue) or asymptomatic (elevated alanine/aspartate aminotransferase [ALT, AST]).
• Acute HCV: if symptoms develop (rare)
  – Onset typically 4 to 12 weeks postexposure
  – Jaundice, dark urine, steatorrhea, nausea, abdominal pain (right upper quadrant [RUQ]), fatigue, low-grade fevers, myalgias, arthralgias

PHYSICAL EXAM
• Typically normal unless advanced fibrosis/cirrhosis
• May have RUQ tenderness/hepatomegaly
• Spider angioma, caput medusa, palmar erythema, jaundice, gynecomastia, Terry nails
• Arthralgias/myalgias, neuropathy, glomerulonephritis, livedo reticularis, lichen planus, pruritus, sicca syndrome, cold agglutinin disease

DIFFERENTIAL DIAGNOSIS
Hepatitis A or B; Epstein-Barr virus (EBV), cytomegalovirus (CMV); alcoholic hepatitis; nonalcoholic steatohepatitis (NASH); hemochromatosis; Wilson disease, \( \alpha_1 \)-antitrypsin deficiency; ischemic, drug-induced, or autoimmune hepatitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Screen adults born between 1945 and 1965, those with exposure risks, current and former IV drug users, HIV-positive individuals, people who engage in high-risk sexual behaviors (partner either HCV positive or IV drug user, multiple partners, or unprotected sex), and patients with persistently elevated ALT.
• CDC algorithm
  – HCV Ab
    o If nonreactive, no further action unless exposure within last 6 months is suspected (test with HCV RNA).
    o If reactive, test HCV RNA.
  – HCV RNA
    o If not detected, no current HCV infection; no further action (2)[A]
• HCV Ab detected 3 to 12 weeks after infection
• HCV RNA detected 1 to 2 weeks after infection
• RNA detectability precedes ALT elevation.
• AST/ALT: often normal, but elevations may persist in chronic HCV; ALT usually is 1 to 2 times upper limit of normal; AST may be normal/elevated.
  – Acute hepatitis C can elevate transaminases and bilirubin (direct and indirect).
• AST/ALT ratio \( \geq 1 \) associated with cirrhosis
  – If AST/ALT ratio \( > 2 \), rule out alcohol abuse.
• Persistent HCV RNA >6 months = chronic HCV

Follow-Up Tests & Special Considerations
• Once diagnosed, test for HCV GT and resistance.
• CBC, metabolic panel, TSH (if using PEG), hepatic function panel, coagulation factors
• IL28B testing: (CC homozygote more likely to clear)
• HBV and HIV coinfection
• Vaccinate if seronegative for hepatitis A/B.
• Pneumococcal polysaccharide vaccine (PPSV23)

Diagnostic Procedures/Other
Evaluate for hepatic fibrosis:
• Indirect markers include multiple clinical prediction models that are based on factors such as age, gender, AST, ALT, platelets, bilirubin. No one model has emerged as the standard. Models include AST to Platelet Ratio Index (APRI), Fibrosis-4 score, FibroIndex, Forns index, HepaScore, and FibroSure.
• Liver imaging: ultrasound (US), CT scan, MRI, transient US elastography, MR elastography
- Liver biopsy (gold standard)
  - Indications: discordant indirect marker results, concurrent non-HCV liver disease, elastography not available
  - Not necessary if diagnosis of hepatocellular carcinoma (HCC) is definitive based on imaging

**Test Interpretation**
- Biopsy measures grade (degree of inflammation) and stage (amount of existing fibrosis).
- Scoring systems: Batts and Ludwig, Metavir, International Association for the Study of the Liver (IASL)
  - Metavir: F0—no fibrosis; F1—portal fibrosis; F2—portal fibrosis with few septa; F3—septal fibrosis; F4—cirrhosis; A (necroinflammation): A0—absent; A1—mild; A2—moderate; A3—severe

**TREATMENT**

**GENERAL MEASURES**
- Report acute HCV to health department.
- Treat patients with virologic evidence of HCV (except patients with a short life expectancy whose prognosis would not be changed by treatment).
- Pretreatment counseling includes a thorough behavioral health and substance abuse history.
- Treat comorbidities prior to initiating antiviral therapy.
- Discuss treatment plan and likelihood of success based on individual factors such as BMI, GT, race, stage of fibrosis, and viral load.
- Sustained virologic response (SVR): undetectable HCV RNA after 12 to 24 weeks of treatment. This is considered a virologic cure of HCV infection.
- HCV cascade: Only 50% of patients with chronic HCV are diagnosed; 25% are HCV RNA confirmed, 15% are prescribed treatment, and 10% achieve SVR (3).

**MEDICATION**

**First Line**
- Acute HCV: OK to delay treatment for 12 to 16 weeks after suspected inoculation to allow for spontaneous clearance. Regimen is the same as for chronic HCV.
- Chronic HCV treatment with traditional agents, pegylated interferon (PEG-IFN) and ribavirin, is often poorly tolerated and no longer preferred.

† Other medications still in use, although recommended for specific circumstances include ombitasvir, paritaprevir, ritonavir, and dasabuvir, ribavirin, simprevir, daclatasvir, and voxilaprevir.
‡ Alternative regimens may be available but may have limitations for use in certain patient populations or lower quality of supporting evidence.

ISSUES FOR REFERRAL
* Consult a specialist experienced in HCV care.
* Refer to liver transplant program if fulminant acute hepatitis, complication of end-stage disease, or HCC.

COMPLEMENTARY & ALTERNATIVE MEDICINE
No evidence for effective complementary therapy in HCV/cirrhosis/HCC

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
* Treat early to prevent fibrosis. If cirrhosis is present, treatment may not prevent decompensation.
* Monitor serial viral load only if on antiviral therapy.
* Some experts recommend abdominal US every 6 months to monitor for HCC.
* Screen for varices with endoscopy if cirrhosis present.

Patient Monitoring
* Serial ALT/AST, renal function, and CBCs
* For 12-week course, follow up 4 weeks after starting therapy and 12 weeks after completing therapy.
  – 4-week HCV RNA: If detectable, recheck at week 6. If RNA has increased >10 times, stop therapy.
  – SVR12: Undetectable HCV RNA 12 weeks after completing therapy generally translates to long-term cure (goal of therapy).
* SVR decreases risk of portal hypertension, hepatic decompensation, and HCC. Monitor for
decompensation (low albumin, ascites, encephalopathy, GI bleed).

**DIET**
- Low-fat, high-fiber diet and exercise to treat obesity/fatty liver
- Extra protein and fluids while on IFN therapy

**PATIENT EDUCATION**
- Avoid alcohol, tobacco, and illicit drugs (including marijuana); refer to rehabilitation/12-step program and monitor for relapse as appropriate.
- Caution with nutritional supplements and herbal medications (may contain hepatotoxins)
  - [http://www.cdc.gov/knowmorehepatitis/](http://www.cdc.gov/knowmorehepatitis/)

**PROGNOSIS**
- For every 100 persons infected with HCV
  - 75 to 85 will develop chronic infection.
  - 60 to 70 will develop chronic liver disease.
  - 10 to 20 will develop cirrhosis over 20 to 30 years (more rapid if older age at infection, male gender, alcohol/substance abuse, HIV/HBV coinfection, or diabetes/insulin resistance)
    - 1–5% annual risk of HCC
    - 3–6% annual risk of hepatic decompensation
- Chronic HCV is curable in ~70% of cases; in noncirrhotic GT 2 or 3, cure rate is ~90%.

**COMPLICATIONS**
- Fibrosis and cirrhosis typically develop within the first 5 to 10 years of infection.
- Acute/subacute hepatic necrosis, liver failure, HCC, transplant and complications, death
- Risk factors for cirrhosis: age, white race, hypertension, alcohol use, anemia; risk for decompensation: diabetes, hypertension, anemia

**REFERENCES**

**ADDITIONAL READING**
SEE ALSO

- Cirrhosis of the Liver; Hepatitis A; Hepatitis B; HIV/AIDS
- Algorithm: Hyperbilirubinemia and Jaundice

CODES

ICD10

- B19.20 Unspecified viral hepatitis C without hepatic coma
- B17.10 Acute hepatitis C without hepatic coma
- B18.2 Chronic viral hepatitis C

CLINICAL PEARLS

- 1 of every 10 patients with hepatitis C has no identifiable risk factors.
- 15–25% of HCV-infected persons spontaneously resolve the infection without specific treatment.
- Assess for coinfections (HBV/HIV) and comorbid substance abuse in patients infected with HCV.
**HERNIA**
Yulibeth Curbelo Peña, MD • Yulibeth Curbelo, MD • Nolberto Adrián Medina-Gallardo, MD, PhD

**BASICS**

**DESCRIPTION**
Areas of weakness or disruption of the abdominal wall through which structures can pass

- **Types**
  - **Inguinal**
    - Direct: acquired; herniation through defect in transversalis fascia of abdominal wall medial to inferior epigastric vessels; increased frequency with age as fascia weakens
    - Indirect: congenital; herniation lateral to the inferior epigastric vessels through internal inguinal ring into inguinal canal. A “complete hernia” descends into the scrotum, an “incomplete hernia” remains in the inguinal canal.
  - Pantaloon: combination of direct and indirect inguinal hernia with protrusion of abdominal wall on both sides of the epigastric vessels
  - Femoral: herniation descending through the femoral canal deep to the inguinal ligament; has a narrow neck and is especially prone to incarceration and strangulation
  - Incisional or ventral: herniation through a defect in the anterior abdominal wall at the site of a prior surgical incision
  - Congenital: herniation through defect in abdominal wall fascia due to collagen deficiency disease
  - Umbilical: defect at umbilical ring
  - Epigastric: protrusion through the middle line above the level of the umbilicus
  - Spigelian hernia: herniation through Spigelian line (lateral border of the rectus abdominis) for a lateral ventral hernia result
  - Sports hernia (not a true hernia): strain or tear of soft tissue of groin or lower abdomen
  - Others: obturator, sciatic, perineal

- **Definitions**
  - Reducible: Extruded sac and its contents can be returned to intra-abdominal position spontaneously or with gentle manipulation.
  - Irreducible/incarcerated: Extruded sac and its contents cannot be returned to original intra-abdominal position.
  - Strangulated: Blood supply to hernia sac contents is compromised.
  - Richter: Partial circumference of the bowel is incarcerated or strangulated. Partial wall damage may occur, increasing potential for bowel rupture and peritonitis.
  - Sliding: Wall of a viscus forms part of the wall of the inguinal hernia sac (i.e., right side—cecum, left side—sigmoid colon).

**Geriatric Considerations**
Abdominal wall hernias increase with advancing age, with significant increase in risk during surgical repair.

**Pregnancy Considerations**
Increased intra-abdominal pressure and hormone imbalances with pregnancy may contribute to increased risk of abdominal wall hernias.

Umbilical hernias are associated with multiple, prolonged deliveries.

**EPIDEMIOLOGY**

**Incidence**
- 75–80% groin hernias: inguinal and femoral
- 2–20% incisional/ventral, depends if prior surgery was associated with infection or contamination
- 3–10% umbilical, considered congenital
- Groin
  - 6–27% lifetime risk in adult men
  - Two peaks: most inguinal hernias present before 1 year of age or after 55 years of age
  - ~50% of children <2 years of age have a patent processus vaginalis, decreasing to 40% after age 2 years. Only between 25% and 50% are clinically significant.
  - Inguinal hernia in <5% of newborns male-to-female ratio 10:1
  - Increased incidence in premature infants
  - Increased incidence in patients with abdominal aortic aneurysms
  - Femoral <10% of all groin hernias, 40% present as a surgical emergency
- Incisional/ventral: ~10–23% of abdominal surgeries complicated by an incisional hernia, most common in upper midline incisions
- Incidence ratio: male = female
- Umbilical: 10–20% of newborns; most close by age 5 years

**Prevalence**
- Groin and inguinal hernias are more prevalent in men; femoral and umbilical more prevalent in women
- Most inguinal hernias are indirect in men and women.
- Incisional/ventral hernias (IVH) are more prevalent in smokers and obese individuals.

**ETIOLOGY AND PATHOPHYSIOLOGY**

Loss of tissue strength and elasticity (especially with aging or congenital defect in abdominal fascia) results in a fascial defect of the abdominal wall. Most pediatric hernias are congenital (e.g., patent processus vaginalis). Most adult hernias are a result of acquired weakness in the tissues of the anterior abdominal wall.

**Genetics**
No known genetic pattern

**RISK FACTORS**
- Increased abdominal pressure, coughing, heavy lifting, constipation, pregnancy, ascites, prostatism, obesity, advancing age (loss of tissue turgor), smoking, steroid use, low birth weight, prematurity
- Age: Femoral and scrotal hernias, along with recurrent groin hernias, are associated with increased risk for acute hernia surgery.

**COMMONLY ASSOCIATED CONDITIONS**
Obesity, chronic obstructive pulmonary disease, multiple abdominal surgeries, pregnancy,
advanced age, Ehlers-Danlos syndrome, Marfan syndrome, polycystic kidney disease (PKD), osteogenesis imperfecta, Down syndrome, abdominal aortic aneurysm

**DIAGNOSIS**

**HISTORY**
- May observe protrusion through abdominal wall during increased intra-abdominal pressure (Valsalva maneuver or cough)
- Pain, nausea, vomiting, bloating; relieved with reclining; may signal complication (e.g., strangulation)

**PHYSICAL EXAM**
- Examine initially with patient standing. During palpation, the patient should cough, strain, or perform Valsalva maneuver to determine the extent of intracavitary content movement. Repeat exam with patient in supine position.
- Inguinal (superior to inguinal ligament)
  - Direct inguinal hernia: Finger in inguinal canal finds defect of the transversalis fascia as a deep (posterior to anterior) bulge palpated with increased intra-abdominal pressure.
  - Indirect inguinal hernia: Finger in inguinal canal finds a persistent process vaginalis as a bulge (lateral to medial) that may extend into scrotum.
- Femoral (inferior to inguinal ligament): bulge in upper middle thigh; neck of the sac protrudes lateral to and below a finger placed on the pubic tubercle.
- Umbilical: palpable protrusion at umbilicus
- Incisional/ventral: palpable protrusion at site of prior abdominal incision or midline superior to the umbilicus
- Epigastric: palpable protrusion off midline above umbilicus

**DIFFERENTIAL DIAGNOSIS**
Lymphadenopathy, hydrocele, lipoma, varices, cryptorchidism, abscess, tumor, sports hernia (athletic pubalgia), pelvic fractures, adductor tears, omphalomesenteric duct, urachal cyst

**DIAGNOSTIC TESTS & INTERPRETATION**
Imaging rarely required; reserve for suspected abdominal hernia or unclear diagnosis; plain radiographs to rule out obstruction
- Ultrasound (US) can assess inguinal hernias.
- CT or tangential radiography for incisional and abdominal wall hernias and postsurgical patients with complaints of abdominal pain
- Herniography is no longer recommended.

**Follow-Up Tests & Special Considerations**
Diagnostic laparoscopy may be beneficial for occult hernias poorly appreciated on exam or with imaging.

**TREATMENT**
- Elective
Elective surgical repair is associated with significantly lower morbidity and mortality.

**Acute setting**
- Pain management for symptomatic hernias
- Strangulated hernias should be surgically repaired early to prevent complications such as necrosis and viscus perforation.
- Manual reduction of incarcerated hernias improves outcomes by allowing for elective repair after swelling and inflammation subside.
- Complication rate is greater with emergent pediatric inguinal hernia repairs compared to elective procedures.
- Acute hernia repair carries a higher morbidity and lower survival rate.
- Laparoscopic repair of IVH is safe, has fewer complications, shorter hospital stays, and possibly a shorter surgical time. Postoperative pain and recurrence rates are similar to open repair.
  - For patients undergoing repair, operative times are shorter for extraperitoneal laparoscopic repair compared to open mesh repair with no difference in complication rates (1)[B].
  - Mesh is generally preferred for hernia repairs; there have been numerous FDA product recalls in the past—primarily related to complications of bowel perforation and obstruction (https://www.fda.gov/medicaldevices/productsandmedicalprocedures/implant).

**MEDICATION**
- **Antibiotics:** Prophylaxis does not reduce wound infections after groin hernia repairs.
- **Pain:** Local anesthetic during surgical repair results in significant reduction of postoperative pain. Tension-free procedures (e.g., Lichtenstein) may be performed under local anesthesia.

**ISSUES FOR REFERRAL**
Warn patients of symptoms or signs of incarceration or strangulation (acute abdominal pain, fever, bloody bowel movements), which mandate immediate evaluation.

**ADDITIONAL THERAPIES**

**Geriatric Considerations**
Use of a truss (external supportive device) for direct inguinal hernias is common; no data regarding efficacy

**SURGERY/OTHER PROCEDURES**
All inguinal hernias should be surgically repaired. Watchful waiting in asymptomatic patients is safe if the patient has significant comorbidities that may compromise urgent repair.
- Incarceration and strangulation are absolute indications for hernia repair.
- Contraindications: patients who are not surgical candidates based on risk factors
  - Avoid elective repair in pregnant patients or patients with active infections.
- Special considerations
  - Umbilical hernias <0.5 cm can usually be followed clinically.
  - Umbilical hernias in children age 2 to 4 years typically close spontaneously.
- Operative times and complication rates are similar when comparing single-incision laparoscopic inguinal hernia repair versus traditional multiport laparoscopic repair (2)[B].
  - “Watchful waiting” is recommended in pregnancy. Elective postpartum repair has similar outcomes and no increased risk of incarceration or strangulation before or during delivery.
  - Women have lower recurrence rates using laparoscopic compared with open method.
– Ascites is not a strict contraindication for repair.

Gold standard
– Inguinal hernia
  o Open: Lichtenstein with mesh (37%): decreased recurrence rates
  o Laparoscopic (14%) with mesh: decreased hospital stay and postoperative pain
    ■ Requires general anesthesia
    ■ Transabdominal preperitoneal (TAPP) versus total extraperitoneal (TEP)
  o Pediatric: Laparoscopic percutaneous repair is an efficient, safe, and effective alternative
to open repair. It is associated with reduced operative times and no increase in
complication or recurrence rates. Avoid mesh in pediatric patients (3)[B].

– Incisional/ventral
  o Laparoscopic repair is effective for most patients with primary or recurrent ventral
hernias; there is <10% recurrence rate.
  – Umbilical
    o Pediatric: open excision with suture closure
    o Adult: Open repair with mesh may reduce hernia recurrence.

Complications
– Recurrence
– Seromas
– Postoperative pain, temporary or chronic: less with laparoscopic versus open technique
  – Wound infection
  – Injury to cord structures in inguinal herniorrhaphy; with nerve injury, most symptoms will
resolve.

ONGOING CARE

PATIENT EDUCATION
Cleveland clinic: http://my.clevelandclinic.org/disorders/hernia/hic_hernia.aspx

PROGNOSIS

Groin (pediatric): low recurrence rates (<3%) with surgery; may spontaneously resolve in
infants
Groin (adult): ≥1% per year risk of bowel strangulation without surgical treatment; 0–10%
postoperative recurrence rates, depending on surgeon experience and procedure type
Incisional/ventral: 3–5% postoperative occurrence: 2–17% postrepair recurrence, increased to
20–46% in larger hernias
Umbilical (pediatric)
  – High rate of spontaneous resolution
  – Hernia less likely to close further in older children and in children with larger defects
Umbilical (adult): up to 11% postoperative recurrence
Epigastric: most ultimately become incarcerated and/or strangulated without surgical
treatment. Recurrence is high due to frequency of missed defects during repair.

ADDITIONAL READING

SEE ALSO

Algorithms: Abdominal Pain, Lower; Intestinal Obstruction; Pelvic Pain

CODES

ICD10

- K46.9 Unspecified abdominal hernia without obstruction or gangrene
- K40.90 Unil inguinal hernia, w/o obst or gangr, not spcf as recur
- K41.90 Unil femoral hernia, w/o obst or gangrene, not spcf as recur

CLINICAL PEARLS

- Inguinal hernias are either direct or indirect:
  - Direct: acquired herniation through defect in transversalis fascia of abdominal wall medial to inferior epigastric vessels
  - Indirect: congenital herniation lateral to the inferior epigastric vessels; a “complete hernia” descends into the scrotum; an “incomplete hernia” remains within the inguinal canal.
- Pantaloon: combined direct and indirect inguinal hernia
- Femoral: descends through the femoral canal deep to the inguinal ligament
- Incisional or ventral: iatrogenic, herniation through a defect at site of a prior surgical incision
- Umbilical: Defect occurs at umbilical ring tissue. Most pediatric umbilical hernias close spontaneously within the first few years of life.
- Incarceration and strangulation are the primary complications associated with hernias.
HERPES EYE INFECTIONS
Stephanie L. Conway-Allen, PharmD, RPh • Gerald Gleich, MD

BASICS

DESCRIPTION
- Eye infection (blepharitis, conjunctivitis, keratitis, stromal keratitis, uveitis, retinitis, glaucoma, or optic neuritis) caused by herpes simplex virus (HSV) types 1 or 2 or varicella-zoster virus (VZV, also known as human herpes virus type 3 [HHV3])
- Categories
  - HSV: can affect many parts of the eye but most often affects the cornea (herpes keratoconjunctivitis); HSV1 > HSV2; can be further divided into primary and recurrent
  - VZV: When VZV is reactivated and affects the ophthalmic division of the 5th cranial nerve, this is known as herpes zoster ophthalmicus (HZO), a type of shingles.
- System(s) affected: eye, skin, central nervous system (CNS) (neonatal)

EPIDEMIOLOGY
- Predominant age: HSV—mean age of onset 37.4 years but can occur at any age, including primary infection in newborns; VZV usually advancing age (>50 years)
- Predominant sex: HSV—male = female; HZO—female > male

Incidence
- HSV keratitis: In the United States, approximated at 18.2 per 100,000 person-years. Incidence is 1.5 million per year worldwide (1).
- VZV: 1 million new cases of shingles per year in the United States; 25–40% develop ophthalmic complications. Temporary keratitis is most common.

Prevalence
- Ocular HSV prevalence estimated at 500,000 in the United States (1)
- VZV: Prevalence of herpes zoster infection is 20–30%. Ocular involvement in 50% if not treated with antivirals (2); overall lifetime prevalence of HZO: 1%.

ETIOLOGY AND PATHOPHYSIOLOGY
- HSV and VZV are Herpesviridae dsDNA viruses.
- HSV: primary infection from direct contact with infected person via saliva, genital contact, or birth canal exposure (neonates)
  - Primary infection may lead to severe disease in neonates, including eye, skin, CNS, and disseminated disease.
  - Recurrent infection is more common overall cause of herpetic eye infections.
- VZV: Primary infection from direct contact with infected person may cause varicella (“chickenpox”) and/or lead to a latent state within trigeminal ganglia.
  - Reactivation of the virus may affect any dermatome (resulting in herpes zoster or “shingles”), including the ophthalmic branch (HZO).

RISK FACTORS
- HSV: personal history of HSV or close contact with HSV-infected person
– General risk factors for reactivation: stress, trauma, fever, UV light exposure, other viral infections
– Risk factors for HSV keratitis: UV laser eye treatment, some topical ocular medications such as prostaglandin analogues and primary/secondary immunosuppression

- HZO
  – History of varicella infection, advancing age (>50 years), sex (female > male), acute/painful prodrome, trauma, stress, immunosuppression (1,3)

**ALERT**
Consider primary/secondary immunodeficiency disorders in all zoster patients <40 years of age (e.g., AIDS, malignancy).

**GENERAL PREVENTION**
- Contact precautions with active lesions (HSV and VZV)
- VZV can be spread to those who have not had chickenpox and are not immunized.
- Varicella recombinant zoster vaccine (Shingrix) (VZV only): 2 doses 2 to 6 months apart recommended by the Centers for Disease Control and Prevention for all persons age 50 years and older; preferred over older vaccine (Zostavax), which can still be used for persons age >60 years unable to take Shingrix (4)
  – Do not give varicella vaccine during an acute infection.
- Acyclovir can be used prophylactically to prevent recurrence of ocular HSV.
- HSV immunization currently being researched (1)

**ALERT**
Zoster vaccination is contraindicated if HIV-positive or other immunocompromised state, pregnancy, or in active untreated tuberculosis (TB).

**Pregnancy Considerations**
- Pregnant women without history of chickenpox should avoid contact with persons with active zoster.
- Pregnancy increases risk of recurrence of HSV/VZV.
- Shingrix and Zostavax vaccinations are both contraindicated during pregnancy.

**COMMONLY ASSOCIATED CONDITIONS**
Primary and secondary immunocompromised states

**DIAGNOSIS**

**HISTORY**
- Varies according to the virus and the ocular structures involved
- History of varicella or herpes simplex infection
- Acute onset, eye pain, headache, photophobia, tearing, ocular redness, decreased or blurry vision (3)
- May present with a prodromal period of fever, malaise, headache, and eye pain before skin eruptions and eye lesions (HZO) (3)

**PHYSICAL EXAM**
Variation according to the virus and ocular structures involved
- HSV most commonly affects the corneal epithelium (1).
- VZV most commonly affects corneal stroma and uvea (3).

Typically unilateral in presentation
- HZO presents as early as 1 to 2 days after unilateral vesicular eruption in a dermatomal pattern (3).

Decreased visual acuity
Conjunctival injection near the limbus
Decreased corneal sensation
Dendritic pattern seen with conjunctival fluorescent staining

**ALERT**
Unilateral dermatomal vesicular rash most commonly in ophthalmic branch (V\textsubscript{1}) of trigeminal nerve (VZV):

- Hutchinson sign: Vesicular lesion on nose from VZV indicates an increased risk of HZO due to involvement of nasociliary branch of trigeminal nerve, which also innervates the eye (3)[A].

**DIFFERENTIAL DIAGNOSIS**
- Any other cause of red, painful eye
  - Bacterial, fungal, allergic, or other viral conjunctivitis
  - Acute angle-closure glaucoma
- Corneal abrasion, recurrent corneal erosion, toxic conjunctivitis
- Temporal arteritis
- Trigeminal neuralgia

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Typically none needed, as diagnosis is primarily based on history and physical exam (3)[A]
- Other
  - Corneal swab for HSV DNA by polymerase chain reaction (PCR) (positive predictive value = 96%)
  - If vesicle present, can perform a Tzanck smear for VZV or HSV (multinucleated giant cells)
  - Antibody titers to assess exposure only; direct fluorescent antibody (DFA); tissue culture

**ALERT**
Urgent ophthalmology referral necessary for slit-lamp exam, dilated fundus exam, and intraocular pressure measurement

**TREATMENT**

**GENERAL MEASURES**
- Avoid contact with nonimmune people.
- No contact lenses should be worn during treatment period.
- Cool compresses
- Artificial tears
- Oral pain medications
MEDICATION

First Line
- HSV corneal epithelial disease
  - Trifluridine 1%: Apply 1 drop q2h while awake to a max of 9 drops daily until reepithelialization occurs and then 1 drop q4h for an additional 7 days.
  - Acyclovir: 400 mg PO 5 times per day for 10 days
  - Ganciclovir: 0.15% gel: Apply 1 drop in eye q3h while awake, ~5× daily, until reepithelialization occurs, and then 1 drop q8h for 7 days.
  - Trifluridine and acyclovir cure about 90% of treated eyes within 2 weeks with no significant differences in effectiveness (5)[A].
  - Evidence conflicting as to whether ganciclovir is as good as or better than acyclovir (5)[A].
  - Epithelial debridement by an ophthalmologist: may accelerate healing in combination with treatment as above (5)[A]
  - Avoid topical steroids.
- Utility of PO antivirals unclear HSV stromal keratitis or uveitis (without epithelial disease): combination of antiviral and steroid treatment; requires ophthalmology evaluation
  - Prednisolone acetate: 1% drops QID with slow taper (6)[A]
  - Consider systemic steroids in severe uveitis (6)[A].
  - Trifluorothymidine: 1% drops QID for prophylaxis while on topical steroids
- HZO
  - Valacyclovir (Valtrex) 1 g PO TID for 7 to 10 days or famciclovir (Famvir) 500 mg PO TID for 7 to 10 days or acyclovir 800 mg PO 5 times a day for 7 to 10 days
  - Valacyclovir and famciclovir result in significant reduction in postherpetic neuralgia (PHN) compared to acyclovir (number needed to treat [NNT] = 3) with equivalent efficacy (7)[A].
  - Topical antibiotic ophthalmic ointment to protect ocular surfaces (e.g., bacitracin, polymyxin B): 0.5-inch ribbon BID to TID for 7 to 10 days (8)[C]
  - If immunocompromised: acyclovir 10 to 15 mg/kg IV q8h for 10 days
  - Prednisolone acetate: 1% drops QID with slow taper with an ophthalmologist (8)[C]
- Cycloplegic agent if anterior uveitis present; intraocular pressure-lowering agent if necessary

Second Line
- HSV: acyclovir 2 g/day PO in divided doses over 10 days in patients intolerant of topical antivirals
- Topical idoxuridine, acyclovir, brivudine, although approved internationally, are not approved for use in the United States.
- Concomitant treatment with interferon may also improve outcomes but is not currently available.

ALERT
HZO: Antiviral therapy is most effective within the first 72 hours of rash onset but should still be initiated >72 hours after onset because of the possible complications of HZO (2)[C].

- Topical antiviral agents
  - Toxic to corneal epithelium, especially after 10 to 14 days of continuous use
- Acyclovir: Reduce dosage in renal insufficiency
- Topical steroids
  - Should only be prescribed by an ophthalmologist
– Contraindicated with active corneal epithelial disease, which is best monitored with a slit lamp
– Can increase intraocular pressure; cause corneal thinning; and, with long-term use, cause cataracts
● Prednisone: caution in immunocompromised patients

ISSUES FOR REFERRAL
Emergent or urgent ophthalmology referral, depending on severity of disease

ADDITIONAL THERAPIES
● Recurrent HSV requires suppressive therapy.
● HZO leading to PHN is very common and can be treated with gabapentin or pregabalin, tricyclic antidepressants, opioids, and/or lidocaine gel.

SURGERY/OTHER PROCEDURES
Corneal transplantation for severe scarring or perforation

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
● Admission criteria/initial stabilization
  – Severe systemic VZV disease
  – Systemic HSV in neonates—see “Herpes Simplex Virus, Pediatric.”
● Discharge criteria: resolution of systemic disease

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
● Monitor with slit-lamp exam q1–2d until improvement and then q3–4d until epithelial defect resolves.
● Weekly after epithelial disease resolves until off topical antivirals

PATIENT EDUCATION
Educate patients about the importance of early recognition of recurrent symptoms and need for prompt evaluation and treatment.

PROGNOSIS
● Many cases are self-limited but, depending on the ocular structure involved, can lead to permanent blindness, especially in the setting of recurrent disease.
● Ocular HSV is the number one cause of infectious blindness worldwide (1).
● Recurrent ocular HSV
  – HSV epithelial disease without treatment
  – Without sequelae, 40% resolve.
  – With treatment, 90–95% resolve without complication.

Pediatric Considerations
● Neonatal primary HSV often disseminated, with high mortality rate; 37% develop vision worse than 20/200.
• Pediatric cases more likely to be bilateral (26%), recurrent (48% in 15 months), and may cause amblyopia

**COMPLICATIONS**

• Recurrence
• Corneal neovascularization and scarring resulting in poor vision
• Neurotrophic ulcer with perforation
• Secondary bacterial or fungal infection
• Secondary glaucoma in 10%
• PHN in 20–40% with VZV, typically longer lasting in older patients
• Vision loss from optic neuritis or chorioretinitis

**REFERENCES**

**SEE ALSO**

• Herpes Simplex; Herpes Simplex Virus, Pediatric; Herpes Zoster (Shingles)
• Algorithm: Eye Pain

**CODES**

**ICD10**

• B00.50 Herpesviral ocular disease, unspecified
• B02.30 Zoster ocular disease, unspecified
• B00.52 Herpesviral keratitis
CLINICAL PEARLS

- HSV and VZV can lead to a wide array of ocular manifestations, ranging from self-limited disease to potentially vision-threatening disease and complications.
- An exam with fluorescein stain should be performed on all patients with possible HSV keratitis or HZO.
- Topical antiviral treatment is appropriate for HSV, but systemic PO antiviral treatment is necessary for HZO.
- An ophthalmologist should be consulted before prescribing topical steroids. All HZO patients should be referred to an ophthalmologist.
- Hutchinson sign (vesicular lesion on nose from VZV) is a strong indicator of HZO.
- Shingrix and Zostavax are both effective at preventing zoster and HZO as well as decreasing the duration of PHN.
HERPES, GENITAL
Cecilia M. Kipnis, MD, FAAFP

BASICS
DESCRIPTION
- Chronic, recurrent herpes simplex virus (HSV) type 1 or 2 infection of any area innervated by the sacral ganglia
- HSV-1 causes anogenital and orolabial lesions.
- HSV-2 causes anogenital lesions.
- Primary episode: occurs in the absence of preexisting antibodies to HSV-1 or HSV-2 (may be asymptomatic)
- First episode nonprimary: initial genital eruption; preexisting antibodies are present.
- Reactivation: recurrent episodes
- Synonym(s): herpes genitalis

EPIDEMIOLOGY
- Most commonly infected from age 15 to 30 years; prevalence increases with age due to cumulative likelihood of exposure.
- Predominant sex: female > male
- Predominant race: non-Hispanic blacks

Incidence
>700,000 new cases per year in the United States

Prevalence
- Overall prevalence of HSV-2 is 10–40% in the general population and up to 60–95% in the HIV-positive population (1).
- Between the ages of 14 and 49 years, the prevalence of HSV-1 in the United States is ~48%. The prevalence of HSV-2 ~12%. The prevalence of HSV-1 was highest (72%) in Mexican Americans and HSV-2 was highest (35%) in non-Hispanic blacks.
- Up to 90% of those who are seropositive lack formal diagnosis.
- Globally, it is estimated that 3.7 billion people are infected with HSV-1 and 140 million with HSV-2.

ETIOLOGY AND PATHOPHYSIOLOGY
- HSV is a double-stranded DNA virus of the Herpetoviridae family (1).
- Spread via genital-to-genital contact, oral-to-genital contact, and via maternal–fetal transmission (2)
- Incubation is 4 to 7 days after exposure.
- Risk of transmission highest when lesions are present
- Viral shedding is possible in the absence of lesions, increasing the risk of transmission (precautions—abstinence, condom use—may not be followed). Viral shedding occurs intermittently and unpredictably.
- HSV infection increases the risk for HIV.
**RISK FACTORS**
- Risk increases with age, number of lifetime partners, history of sexually transmitted infections (STIs), history of HIV, sexual encounters before the age of 17 years, and partner with HSV-1 or HSV-2.
- Infection with HSV-1 confers 3-fold risk of infection with HSV-2.
- Immunosuppression, fever, stress, and trauma increase risk of reactivation.

**COMMONLY ASSOCIATED CONDITIONS**
Syphilis, HIV, chlamydia, gonorrhea, and other STIs

**DIAGNOSIS**

**HISTORY**
- Many patients are asymptomatic (74% of HSV-1 and 63% of HSV-2) or do not recognize clinical manifestations of disease (2).
- If symptoms are present during primary episode, they are often more severe, longer in duration, and associated with constitutional symptoms.
- Common presenting symptoms (primary episode): multiple genital ulcers, dysuria, pruritus, fever, tender inguinal lymphadenopathy, headache, malaise, myalgias, cervicitis/dyspareunia, urethritis (watery discharge)
- First episode, nonprimary: In general, symptoms are less severe than primary episode.
- Common presenting symptoms for recurrent episodes: prodrome of tingling, burning, or shooting pain (2 to 24 hours before lesion appears); single ulcer; lesion can be atypical in appearance; dysuria; pruritus (lasting 4 to 6 days on average)
- Recurrent episodes are more frequent with HSV-2 than with HSV-1, especially the 1st year after infection. Recurrences are less frequent over time.
- Less common presentations: constipation (from anal involvement causing tenesmus), proctitis, stomatitis, pharyngitis, sacral paresthesias

**PHYSICAL EXAM**
- Lesions around groin/perineum and within anus, vagina, and on cervix
- Lesion may appear as papular, vesicular, pustular, ulcerated, or crusted; can be in various stages
- Inguinal lymphadenopathy
- Extranodal manifestations include meningitis, recurrent meningitis (Mollaret syndrome), sacral radiculitis/paresthesias, encephalitis, transverse myelitis, and hepatitis.

**Pediatric Considerations**
- Neonatal infection occurs in 20 to 50/100,000 live births; 80% of infections result from asymptomatic maternal viral shedding during an undiagnosed primary infection in the 3rd trimester.
- Transmission ranges from 30% to 50% if the primary episode is near time of delivery. This risk is higher with HSV-1 than with HSV-2. Neonatal disease is associated with high morbidity and mortality.
- Suspect sexual abuse with genital lesions in children.

**DIFFERENTIAL DIAGNOSIS**
HIV; syphilis; chancroid
Herpes zoster
Ulcerative balanitis
Granuloma inguinale; lymphogranuloma venereum
Cytomegalovirus; Epstein-Barr virus
Drug eruption; trauma
Behçet syndrome
Neoplasia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Confirm clinical diagnosis with laboratory testing.
- Viral isolation (swab or scraping) for culture or PCR
  - Use Dacron or polyester-tipped swabs with plastic shafts (cotton tips/wood shafts inhibit viral growth and/or replication) (1).
  - Culture by unroofing vesicle to obtain fluid sample. Specificity >99%; sensitivity depends on sample: 52–93% for vesicle, 41–72% for ulcer, 19–30% for crusted lesion (1,3).
  - Culture requires timely transport of live virus to the laboratory in appropriate medium at 4°C.
  - PCR has the greatest sensitivity (98%) and specificity (>99%) but is also expensive and not readily available. It can increase detection rates by up to 70% (4); used primarily for CSF (1).
- Type-specific serologic assays
  - Seroconversion occurs 10 days to 4 months after infection (3). Antibody testing is not necessary if a positive culture or PCR has been obtained.
  - IgM antibody testing is not useful because HSV IgM is often present with recurrent disease and does not distinguish new from old infection.
  - Western blot (gold standard) and type-specific IgG antibody (glycoprotein G) enzyme-linked immunosorbent assay (ELISA) are used to discriminate between HSV-1 and HSV-2 (3)[B].
  - Western blot is >97–99% sensitive and specific but labor intensive and not readily available (1,3).
  - ELISA 81–100% sensitive; 93–100% specific (1) for HSV-2 but lower for HSV-1 detection. False positives are possible.
  - Screening with type-specific antibody is not generally recommended for (3):
    - Asymptomatic patients with HIV infection
    - Discordant couples (one partner with known HSV, the other without)
    - Recurrent symptoms but no active lesions

TREATMENT

GENERAL MEASURES
- Ice packs to perineum, sitz baths, topical anesthetics
- Analgesics, NSAIDs

MEDICATION
Start antiviral medications within 72 hours of onset of symptoms (including prodrome). After 3 days, antivirals may help if new lesions form or for significant pain.

**First Line**

- **Acyclovir (4)[A]:** the most studied antiviral in genital herpes; decreases pain, duration of viral shedding, and time to full resolution
  - **Primary episode**
    - 400 mg PO TID for 7 to 10 days
    - 200 mg PO 5 times a day for 7 to 10 days
    - Longer if needed for incomplete healing
  - **Episodic therapy**
    - 200 mg 5 times per day for 5 days
    - 400 mg TID for 5 days
    - 800 mg BID for 5 days
    - 800 mg TID for 2 days
  - **Daily suppression**
    - 400 mg BID
  - **Severe, complicated infections (IV therapy)**
    - 5 to 10 mg/kg/dose q8h until clinical improvement; switch to PO therapy to complete a 10-day course.
  - **HIV infection:** 400 mg PO 3 to 5 times per day until clinical resolution is attained
  - **Precautions**
    - Modify dose in renal insufficiency.

- **Valacyclovir (Valtrex) (4)[A]:** prodrug of acyclovir, improved bioavailability, less frequent dosing
  - **Primary episode**
    - 1 g PO BID for 7 to 10 days
  - **Episodic therapy**
    - 500 mg PO BID for 3 to 5 days
    - 1 g PO daily for 5 days
  - **Daily suppression**
    - 500 mg PO daily
    - 1 g PO daily

- **Famciclovir (Famvir) (4)[A]**
  - **Primary episode**
    - 250 mg PO TID for 7 to 10 days
  - **Episodic therapy**
    - 125 mg PO BID for 5 days
    - 1 g PO BID for 1 day
  - **Daily suppression:** 250 mg PO BID

**ISSUES FOR REFERRAL**

For acyclovir-resistant HSV, in consultation with infectious disease specialist (4)[A]:

- **Foscarnet:** 40 mg/kg/dose IV q8h until clinical resolution
  - Associated with significant toxicity
- **Cidofovir:** 5 mg/kg IV once weekly
Pregnancy Considerations

ACOG clinical management guidelines (4)[A],(5)[C]:

- **Screening:** Pregnant women negative for HSV-1 and HSV-2 antibodies should avoid sexual contact in the 3rd trimester if their partner is antibody positive.
- **Suppressive therapy:** Pregnant women with a history of genital herpes should be offered suppression treatment starting at 36 gestational weeks until delivery to decrease reactivation rate and reduce the risk of neonatal infection:
  - Acyclovir 400 mg PO TID
  - Valacyclovir 500 mg PO BID
- Monitor for outbreaks during pregnancy and examine for any lesions at the onset of labor. C-section is recommended if prodromal symptoms or lesions are present at onset of labor.

Pediatric Considerations

- High-risk infants include those with active symptoms or lesions, those delivered vaginally with maternal lesions present, and those born during a primary maternal episode. Monitor closely; obtain diagnostic laboratory specimens (HSV PCR and ocular, nasal, anal, and oral cultures). If symptomatic, require prolonged treatment:
  - Acyclovir 20 mg/kg IV q8h for 14 days if skin or mucosal lesions, 21 days if disseminated or CNS disease (4)[A]
- Low-risk infants who are asymptomatic can be observed while obtaining serum HSV PCR and ocular, nasal, anal, and oral cultures.
- Infants with possible HSV infection should be isolated from other neonates; maternal separation is not necessary, and breastfeeding is not contraindicated.

ONGOING CARE

GENERAL PREVENTION

- Use barrier contraception and avoid sexual contact when symptoms/lesions are present.
- Abstinence is the only means of complete protection.

Patient Monitoring

Test for HIV and other STIs.

PATIENT EDUCATION

- Patient education helps in treatment of subsequent outbreaks and to reduce risk of transmission:
  - Options include daily suppressive therapy and episodic therapy.
  - Alert partners of history prior to sexual activity.
  - Avoid sexual contact when symptoms or lesions are present.
  - Viral shedding and transmission can occur when symptoms/lesions are NOT present.
    - Shedding increased with HSV-2 and HIV.
  - 100% condom use reduces HSV-2 transmission risk by 30%.
  - Sexual activity between concordant couples (i.e., both partners with the same type of herpes [HSV-1 or HSV-2]) does not increase risk of outbreaks.
  - Ensure maternity care team knows HSV status.
Centers for Disease Control and Prevention: http://www.cdc.gov/

PROGNOSIS
- Resolution of signs/symptoms: 3 to 21 days
- Average recurrence rate is one to four episodes per year (2).
- Antivirals do not eliminate virus from body but can reduce transmission, shedding, and outbreaks.

Pediatric Considerations
Neonatal infection survival rates: localized >95%, CNS 85%, systemic 30%

COMPLICATIONS
Behavioral issues include lowered self-esteem, guilt, anger, depression, fear of rejection, and fear of transmission to partner.

Algorithm: Genital Ulcers
CODES

ICD10
- A60.00 Herpesviral infection of urogenital system, unspecified
- A60.04 Herpesviral vulvovaginitis
- A60.09 Herpesviral infection of other urogenital tract

CLINICAL PEARLS
- Genital herpes is caused by HSV-1 and/or HSV-2.
- Many seropositive individuals are unaware that they are infected.
- Most primary episodes are asymptomatic.
- Viral shedding occurs in the absence of lesions.
- Meticulous (100%) condom use decreases transmission of HSV.
HERPES SIMPLEX
Sonia Rivera-Martinez, DO • Sharon L. Koehler, DO, FACS

BASICS

DESCRIPTION
- Characteristic vesicular rash primarily located in oral and genital regions as the result of infection with:
  - Herpes simplex virus (HSV)-1 blisters mostly on lips, in mouth, face, eyes
  - HSV-2 primarily genital herpes, although cross-reactivity is common (HSV-1 can cause genital sores through oral–genital contact)
- Associated with a wide range of sequelae. Complexity and variation of presentation depends on the age and immune status of host, whether the infection is primary or recurrent and the degree of dissemination.
- Viral shedding is typically greatest in the first (primary) infection and lessens with recurrences.
- Meningitis/encephalitis and pneumonia are serious systemic manifestations associated with HSV infection.

EPIDEMIOLOGY
- Predominant age: affects all ages; however, most HSV-1 is acquired in childhood, and most HSV-2 is acquired in young–middle adulthood.
- Predominant sex: male = female

Incidence
- >1 million new cases of HSV per year
- HSV can reactivate, causing recurrent disease.

Prevalence
- Widespread; 1–25% of adults may shed HSV-1 or HSV-2 at any given time. Many are unaware of their infection status.
- Prevalence of antibodies to HSV-1 is 90% by adulthood in the general population. 30% of adults have antibodies to HSV-2.

ETIOLOGY AND PATHOPHYSIOLOGY
HSV-1 and HSV-2 are double-stranded DNA viruses from the family Herpesviridae. HSV-1 and HSV-2 are transmitted by contact with infected skin during periods of viral shedding. Transmission also occurs vertically during childbirth. Most often, HSV-1 is associated with oral lesions and HSV-2 with genital lesions.

RISK FACTORS
- Immunocompromised state
  - Chemotherapy, malignancy/chronic disease states such as diabetes or AIDS, old age
- Atopic eczema, especially in children
- Prior HSV infection
- Sexual intercourse with infected person (Condoms help minimize HSV transmission, but lesions outside condom-protected areas can spread virus.)
Occupational exposure
– Dental professionals at higher risk for HSV-1 and resulting herpetic whitlow
– Neonatal herpes simplex: Primary infection is life-threatening and usually acquired by vaginal birth to an infected mother; risk is greatest in mothers with primary genital herpes infection; incubation is usually from 5 to 7 days (rarely 4 weeks); cutaneous, mucous membrane, or ocular signs seen in only 70%

GENERAL PREVENTION
– If active lesions are present, avoid direct contact with immunocompromised people, elderly, and newborns.
– Hand hygiene
– Kissing, sharing beverages, and sharing utensils/toothbrushes can transmit HSV.
– Genital herpes: Avoid sexual contact if active lesions (herpes simplex is also transmitted when disease appears to be inactive); discuss condom benefits and limits; consider antiviral therapy to reduce viral shedding; encourage safe sex.

COMMONLY ASSOCIATED CONDITIONS
– Erythema multiforme: 50% of cases associated with HSV-1 or HSV-2
– Screen all severe, treatment-resistant, or unusual HSV for concurrent HIV infection.

DIAGNOSIS

HISTORY
– Many patients are unaware of a known exposure.
– Prodrome of fatigue, low-grade fever, itching, tingling, or hot skin for several days immediately prior to outbreak of characteristic vesicular rash
– Herpes labialis is precipitated by sunlight, fever, trauma, menses, and stress; prodrome of pain, burning, and itching commonly occurs 6 to 48 hours before vesicles appear.

PHYSICAL EXAM
– Vesicles are often clustered and become painful ulcerated lesions, often with erythematous base.
– Primary genital herpes: See “Herpes, Genital.”
– Primary herpetic gingivostomatitis and pharyngitis: usually in early childhood; incubation from 2 to 12 days, followed by fever, sore throat, pharyngeal edema, and erythema
  – Small vesicles develop on pharyngeal and oral mucosa, rapidly ulcerate, and increase in number to involve soft palate, buccal mucosa, tongue, floor of mouth, lips, and cheeks; tender, bleeding gums; cervical adenopathy; fever, general toxicity, poor oral intake, and excess salivation contribute to dehydration; autoinoculation of other sites may occur; resolves in 10 to 14 days
– Primary herpes keratoconjunctivitis: unilateral conjunctivitis with regional adenopathy, blepharitis with vesicles on lid marginal keratitis with dendritic lesions or with punctate opacities; lasts 2 to 3 weeks; systemic involvement prolongs process.
– Eczema herpeticum: diffuse poxlike eruption complicating atopic dermatitis; sudden appearance of lesions in typical atopic areas (upper trunk, neck, head); high fever, localized edema, adenopathy
– Herpetic whitlow: localized infection of affected finger with intense itching and pain, followed
by vesicles that may coalesce with swelling and erythema. Mimics pyogenic paronychia; neuralgia and axillary adenopathy are possible; heals in 2 to 3 weeks
- Congenital infection through transplacental transfer may present with jaundice, hepatosplenomegaly, disseminated intravascular coagulation (DIC), encephalitis, seizures, temperature instability, chorioretinitis, and conjunctivitis with/without vesicles.
- Recurrent diseases from endogenous reactivation
  - Herpes labialis: recurrent lesions with HSV-1; usually <1 recurrence per 6 months, but 5–25% may have >1 attack per month; vesicles often at vermilion border, ulcerate and crust within 48 hours; heal within 8 to 10 days; may have local adenopathy
  - Ocular herpes: may recur as keratitis, blepharitis, or keratoconjunctivitis; dendritic ulcers, decreased corneal sensation, decreased visual acuity; uveitis may cause permanent visual loss.

DIFFERENTIAL DIAGNOSIS
- Impetigo: honey-crusted vesicles
- Aphthous stomatitis: grayish, shallow erosions with ring of hyperemia of anterior in mouth and lips
- Herpes zoster: unilateral dermatome distribution
- Syphilitic chancre: painless ulcer
- Folliculitis: may mimic “shave bumps” in genital area
- Herpangina: Vesicles predominate on anterior tonsillar pillars, soft palate, uvula, and oropharynx but not more anteriorly on lips/gums (usually caused by group A coxsackievirus).
- Stevens-Johnson syndrome

DIAGNOSTIC TESTS & INTERPRETATION
- Screen for other sexually transmitted infections (STIs) in patients with primary genital herpes.
- Viral: HIV, hepatitis B and C, and human papillomavirus (HPV) have crossover.
- Bacterial: Screen for concurrent gonorrhea, chlamydia in new primary genital outbreaks.

Initial Tests (lab, imaging)
- Tzanck smear shows multinucleated giant cells often with eosinophilic intranuclear inclusions (scrape material from lesion to slide, fix with ethanol/methanol, stain with Giemsa or Wright stain); varicella (herpes zoster) has identical findings.
- HSV culture: Swab and plate on viral-specific media. Sample may need to be refrigerated; can take up to 6 days to be positive; highly specific, hence, reliable if positive but has 20% false-negative rate
- HSV type-specific antibody tests distinguish between HSV-1 and HSV-2.
  - Polymerase chain reaction (PCR), direct fluorescent antibody (DFA), enzyme-linked immunosorbent assay, and Western blot
  - 3 weeks after infection, 50% of those infected test positive; 70%, 6 weeks after infection; by 16 weeks, nearly all infected test positive

Diagnostic Procedures/Other
Biopsy is occasionally needed to confirm diagnosis.

Test Interpretation
- Intraepithelial edema (ballooning degeneration) and intracellular edema
- Brain biopsy (in encephalitis) shows hemorrhagic necrosis of gray and white matter with acute
and chronic inflammation, thrombosis, and fibrinoid necrosis of parenchymal vessels; intranuclear inclusions in astrocytes, oligodendroglia, and neurons

**TREATMENT**

**GENERAL MEASURES**

- Cool dressings moistened with aluminum acetate solution
- Pouring a cup of warm water over genitals while urinating or by sitting in a warm bath while urinating (sitz baths) if lesions are causing urinary difficulty
- Children with gingivostomatitis who resist oral intake due to pain or extensive skin disease (eczema herpeticum) may require IV hydration.

**MEDICATION**

**First Line**

- Begin promptly, preferably in prodromal phase.
- Acyclovir (generic)
  - Mucocutaneous (or genital) HSV
    - Primary/first infection: 400 mg TID or 200 mg 5 times per day for 7 to 10 days
    - If severe, start with IV q8h dosing for the first few days, then complete 10-day course PO route.
    - Recurrence: 400 mg PO TID for 5 days or 800 mg BID for 5 days or 800 mg TID for 2 days
  - Suppression: 400 mg BID daily (1)[B]
  - Keratitis HSV: 400 mg PO 5 times per day; topical treatment is preferred as first line.
  - Pediatric dosing: neonatal herpes simplex or encephalitis: 60 mg/kg/day IV divided q8h for 14 to 21 days (2)[B]
    - Older (>3 months of age) immunocompetent is weight-based dosing (40 to 80 mg/kg/day [max 1,000 mg/day] divided q8h for 5 to 7 days).
    - Safe in pregnancy and lactation—Category B
  - Recurrent herpes labialis: 800 to 1,600 mg/day for prevention (3,4)[B]
- Penciclovir (Denavir): 1% cream. Apply to oral lesions q2h during waking hours for 4 days (5)[B].
- Valacyclovir (Valtrex)
  - Primary genital herpes: 1 g PO BID for 7 to 10 days. Recurrent genital herpes: 500 mg PO BID for 3 days; suppression: 500 to 1,000 mg PO daily (depending on frequency of outbreaks); labialis HSV (cold sores/oral lesions): 2,000 mg PO q12h for 1 day (3,4,6)[B]
  - 500-mg daily dose if suppression is needed/desired
  - Recurrent herpes labialis: 500 mg/day for 4 months for prevention (3)[B]
- Famciclovir (Famvir)
  - Primary genital herpes: 250 mg PO TID for 7 to 10 days
  - Recurrence: 125 mg PO BID for 5 days or 1,000 mg PO BID for 1 day
  - Suppression: 250 mg PO BID

**Precautions**

- Renal dosing for all oral antivirals
- Significant possible interactions: Probenecid with IV acyclovir and possibly probenecid
with valacyclovir may reduce renal clearance and elevate antiviral drug levels.

**Second Line**
- Foscarnet
  - Drug of choice for acyclovir resistance in immunocompromised persons with systemic HSV
  - 40 mg/kg IV q8h (Assume valacyclovir and famciclovir resistance also if acyclovir resistance occurs.)
- Other topicals
  - Ophthalmic preparations for herpes keratoconjunctivitis; acyclovir, vidarabine (Vira-A), ganciclovir, trifluridine
  - Topical acyclovir and penciclovir improve recurrent herpes labialis healing times by ~10% (3)[B].
  - Topical analgesics: Lidocaine 2% or 5% helps reduce pain associated with vulvar and penile outbreaks.
- Over-the-counter topical antivirals: docosanol

**ISSUES FOR REFERRAL**
Refer recurrent cases of herpes keratoconjunctivitis to an ophthalmologist.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Pregnancy considerations
  - Cesarean section and/or acyclovir are indicated if any active genital lesions (or prodrome) present at time of delivery; consider cesarean delivery if primary genital herpes is suspected within previous 4 weeks (5,6)[B].
  - Daily oral antivirals after 36 weeks of pregnancy in women with history of genital herpes help to prevent outbreak around the time of delivery.
  - Avoid fetal scalp electrodes, forceps, vacuum extractor, and artificial rupture of membranes if mother has history of genital HSV.
  - Risk of viral shedding at delivery from asymptomatic recurrent genital HSV is low (~1.6%).
- Pediatric considerations
  - Neonates with likely exposure (high index of suspicion) at birth or those who exhibit signs of HSV infection should have body fluids cultured and immediately start treatment (IV acyclovir).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- For most routine cases, follow-up is not necessary. Lesions and symptoms resolve rapidly within 10 days. Extensive cases should be rechecked in 1 week; monitor for secondary bacterial infections.
- Consider long-term suppression.

**DIET**
If oral lesions are present, avoid salty, acidic, or sharp foods (e.g., snack chips, orange juice).

**PATIENT EDUCATION**
- Explain the natural history that timing of exposure is difficult to determine and that the virus
will remain in the body indefinitely. Acknowledging and discussing psychological impact of the diagnosis helps to reduce stigmatization.

- Emphasize personal hygiene to avoid self-spreading to other body areas (autoinoculation) or exposing others. Frequent hand washing; avoid scratching; cover active, moist lesions.
- Reinforce safe sexual practices.

**PROGNOSIS**

- Usual duration of primary disease is 5 days to 2 weeks.
- Antiviral treatment shortens duration, reduces complications, and mitigates recurrences (if used for suppression).
- Viral shedding during recurrence is briefer than with primary disease; frequency of recurrence is variable and depends on individual host factors.
- Newborns/immunocompromised individuals are at highest risk for major morbidity/mortality.
- HSV is never eliminated from the body but stays dormant in dorsal root ganglia and can reactivate, causing recurrent symptoms and lesions.

**COMPLICATIONS**

- Herpes encephalitis: Brain biopsy may be needed for diagnosis.
- Herpes pneumonia

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

- Herpes, Genital
- Algorithm: Genital Ulcers
CODES

ICD10
- B00.9 Herpesviral infection, unspecified
- A60.00 Herpesviral infection of urogenital system, unspecified
- B00.1 Herpesviral vesicular dermatitis

CLINICAL PEARLS
- Up to 25–30% of the U.S. population have serologic evidence of genital herpes (HSV-2), and >80% are seropositive for HSV-1.
- Most individuals are unaware they are infected, allowing for asymptomatic viral transmission.
- Viral suppression for patients with frequent recurrences reduces transmission and decreases outbreak frequency.
HERPES ZOSTER (SHINGLES)
Shane L. Larson, MD

BASICS

DESCRIPTION
- Results from reactivation of latent varicella-zoster virus (VZV) (human herpesvirus type 3) infection
- Postherpetic neuralgia (PHN) is defined as pain persisting at least 1 month after rash has healed. The term zoster-associated pain is more clinically useful.
- Usually presents as a painful unilateral vesicular eruption with a dermatomal distribution
- System(s) affected: nervous; integumentary; exocrine
- Synonym(s): shingles

EPIDEMIOLOGY

Incidence
- Incidence increases with age—2/3 of cases occur in adults age ≥50 years. Incidence is increasing overall as the U.S. population ages.
- Herpes zoster: 4/1,000 person-years
- PHN: 18% in adult patients with herpes zoster; 33% in patients ≥79 years of age
- Individual lifetime risk of 30% in the United States

Prevalence
~1 million new cases of herpes zoster annually in the United States

Pregnancy Considerations
May occur during pregnancy

Geriatric Considerations
- Increased incidence of zoster outbreaks
- Increased incidence of PHN

Pediatric Considerations
- Occurs less frequently in children
- Has been reported in newborns infected in utero

ETIOLOGY AND PATHOPHYSIOLOGY
Reactivation of VZV from dorsal root/cranial nerve ganglia. Upon reactivation, the virus replicates within neuronal cell bodies, and virions are carried along axons to dermatomal skin zones, causing local inflammation and vesicle formation.

RISK FACTORS
- Increasing age
- Immunosuppression (malignancy or chemotherapy)
- Physical trauma
- Female
- HIV infection
Spinal surgery

**GENERAL PREVENTION**
- Recombinant herpes zoster vaccination (Shingrix) is approved and recommended by the Centers for Disease Control and Prevention for adults 50 years and older (1).
- Shingrix is recommended for adults who previously received Zostavax (live attenuated) and is the preferred vaccine.
- Live VZV vaccine (Zostavax) is contraindicated in immunosuppressed persons, patients with HIV and CD4 counts <200, patients undergoing cancer treatment, and patients with hematologic or lymphatic cancer (1,2).
- Patients with active zoster may transmit disease-causing varicella virus—typically through direct contact.

**COMMONLY ASSOCIATED CONDITIONS**
Immunocompromised states, HIV infection, posttransplantation, immunosuppressive drugs, and malignancy

**DIAGNOSIS**

**HISTORY**
- Prodromal phase (sensory changes over involved dermatome prior to rash)
  - Tingling, paresthesias
  - Itching
  - Boring “knife-like” pain
  - Allodynia and hyperalgesia
- Acute phase
  - Constitutional symptoms (e.g., fatigue, malaise, headache, low-grade fever) are variable.
  - Dermatomal rash

**PHYSICAL EXAM**
- Acute phase
  - Rash: initially erythematous and maculopapular; evolves to characteristic grouped vesicles usually in one dermatome but may affect two to three adjacent dermatomes
  - Thoracic and lumbar dermatomes are most commonly involved sites (2).
  - Vesicles become pustular and/or hemorrhagic in 3 to 4 days.
  - Weakness in distribution of rash (1%)
  - Rash crusts and resolves by 14 to 21 days.
- Possible sine herpete (zoster without rash) and other chronic disorders associated with VZV without the typical rash
  - Herpes zoster ophthalmicus (HZO). Vesicles on tip of the nose (Hutchinson sign) indicate involvement of the external branch of cranial nerve V and are associated with increased incidence of HZO.
- Chronic phase
  - PHN is the most common complication (15% overall; increases with age).
  - 1–5% of cases may affect the motor nerves, causing weakness (zoster motorius), facial nerve involvement (Ramsay Hunt syndrome), spinal motor radiculopathies.
  - Lesions usually heal 2 to 4 weeks after onset, but scarring and pigmentation changes are
DIFFERENTIAL DIAGNOSIS

Rash
- Herpes simplex virus
- Coxsackievirus
- Contact dermatitis
- Superficial pyoderma

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Rarely necessary. Clinical appearance is distinct.

Follow-Up Tests & Special Considerations
- Viral culture
- Tzanck smear (does not distinguish from herpes simplex, and false-negative results occur)
- Polymerase chain reaction
- Immunofluorescent antigen staining
- Varicella-zoster–specific IgM

Test Interpretation
- Multinucleated giant cells with intralesional inclusion
- Lymphatic infiltration of sensory ganglia with focal hemorrhage and nerve cell destruction

TREATMENT

GENERAL MEASURES
- Treat to control symptoms and prevent complications.
- Antiviral therapy decreases viral replication; lessens inflammation and nerve damage and reduces the severity and duration of long-term pain.
- Prompt analgesia may shorten the duration of zoster-associated pain.
- Calamine and colloidal oatmeal may help reduce itching and burning.

MEDICATION

First Line
- Acute treatment
  - Antiviral agents initiated within 72 hours of skin lesions help relieve symptoms, speed resolution, and prevent or mitigate PHN (3)[A].
  - Antivirals do not significantly reduce the incidence of PHN (4)[A].
  - Valacyclovir: 1,000 mg PO TID for 7 days
  - Famciclovir: 500 mg PO TID for 7 days
  - Acyclovir: 800 mg q4h (5 doses daily) for 7 days
  - In children, oral acyclovir is the drug of choice.
- Analgesics (acetaminophen, nonsteroidal anti-inflammatory drugs)
- Corticosteroids do not prevent PHN but may accelerate resolution of acute neuritis.
  - Tricyclic antidepressants (TCAs); amitriptyline 10 to 25 mg at bedtime and other low-dose TCAs relieve pain acutely and may reduce pain duration; dose may be titrated up to 75 to
150 mg/day as tolerated.
- Lidocaine patch 5% (Lidoderm) applied over painful areas (limit three patches simultaneously or trim a single patch) for up to 12 hours may be effective.
- Gabapentin: 300 to 600 mg TID for pain; limited by adverse effects
- Capsaicin cream and other analogesics may be useful adjuncts. Use opioids sparingly.
- Capsaicin 8% patch or plaster provides pain relief for patients with PHN (5)[C]; better tolerated when initially applied with topical anesthetic
- Pregabalin: 150 to 300 mg/day divided BID or TID reduces pain; use is limited by side effects.

- Prevention of PHN and zoster-associated pain: there are no treatments to prevent PHN. Treatment may, however, shorten duration and/or reduce severity of symptoms.
  - Antiviral therapy with valacyclovir, famciclovir, or acyclovir given during acute skin eruption may decrease the duration of pain.
  - Low-dose amitriptyline (25 mg at bedtime) started within 72 hours of rash onset and continued for 90 days may reduce PHN incidence/duration.
- Paravertebral blockade: Nerve blocks during the acute phase shorten the duration of pain; somatic blocks, paravertebral blocks, and repeated/continuous epidural blocks can be used to prevent PHN (6)[A].
  - Insufficient evidence to suggest that corticosteroids reduce incidence, severity, or duration of PHN

- Precautions
  - Assess renal function prior to using valacyclovir, famciclovir, acyclovir, gabapentin, and pregabalin.
  - Valacyclovir, famciclovir, and acyclovir are pregnancy Category B.

Second Line
Numerous therapies have been advocated, but supporting evidence to routinely recommend is lacking.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Cupping therapy (traditional Chinese medicine) shows potential benefit, but evidence is conflicting.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Outpatient treatment, unless disseminated or occurring as complication of serious underlying disease requiring hospitalization
- Consultation with ophthalmology for ophthalmic involvement (VZO).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Refer to ophthalmology if concern that ophthalmic branch of the trigeminal nerve is involved.

Patient Monitoring
Follow duration of symptoms—particularly PHN. Consider hospitalization if symptoms are severe; patients are immunocompromised; >2 dermatomes are involved; serious bacterial superinfection, disseminated zoster, ophthalmic involvement, or meningoencephalitis develops.
DIET
No special diet

PATIENT EDUCATION
- The rash typically lasts 2 to 3 weeks.
- Encourage good hygiene and proper skin care.
- Warn of potential for dissemination (dissemination must be suspected with constitutional
  illness signs and/or spreading rash).
- Warn of potential PHN.
- Warn of potential risk of transmitting illness (chickenpox) to susceptible persons.
- Seek medical attention if any eye involvement.

PROGNOSIS
- Immunocompetent individuals should experience spontaneous and complete recovery within a
  few weeks.
- Acute rash typically resolves within 14 to 21 days.
- PHN may occur in patients despite antiviral treatment.

COMPLICATIONS
- PHN
- HZO: 10–20%
- Superinfection of skin lesions
- Meningoencephalitis
- Disseminated zoster
- Hepatitis; pneumonitis; myelitis
- Cranial and peripheral nerve palsies
- Acute retinal necrosis

REFERENCES

ADDITIONAL READING

SEE ALSO
- Bell Palsy; Chickenpox (Varicella Zoster); Herpes Eye Infections; Herpes Simplex
- Algorithm: Genital Ulcers

CODES

ICD-10
- B02.9 Zoster without complications
- B02.29 Other postherpetic nervous system involvement

CLINICAL PEARLS
- Antiviral therapy within 72 hours of the onset of rash is most effective.
- Patients with active herpes zoster can transmit clinically active disease (chickenpox) to susceptible individuals.
- Shingrix (recombinant) is the recommended vaccine for healthy adults 50 years and older, including those who previously received Zostavax (live attenuated), to prevent shingles and related complications.
HICCUPS
Maria Montanez Villacampa, MD • Renee F. del Carmen, MD • Nida Hussain, MD

BASICS

DESCRIPTION
- Hiccups are caused by a repetitive sudden involuntary contraction of the inspiratory muscles (predominantly the diaphragm) and terminated by the abrupt closure of the glottis, which stops the inflow of air and produces a characteristic sound.
- Hiccups are classified based on their duration: Hiccup bouts last up to 48 hours; persistent hiccups last >48 hours but <1 month; intractable hiccups last for >1 month.
- System(s) affected: nervous, pulmonary
- Synonym(s): hiccoughs; singultus

Geriatric Considerations
Can be a serious problem, particularly among the elderly

Pregnancy Considerations
- Fetal hiccups are rhythmic fetal movements (confirmed sonographically) that can be confused with contractions.
- Fetal hiccups are a sign of normal neurologic development (1).

EPIDEMIOLOGY
- Predominant age: all ages (including fetus)
- Predominant sex: male > female (4:1)

Prevalence
Self-limited hiccups are extremely common, as are intra- and postoperative hiccups.

ETIOLOGY AND PATHOPHYSIOLOGY
- Results from stimulation of ≥1 limbs of the hiccup reflux arc (vagus and phrenic nerves) with a “hiccup center” located in the upper spinal cord and brain (2)
- In men, >90% have an organic basis; whereas in women, a psychogenic cause is more common.
- Specific underlying causes include:
  - CNS disorders: vascular lesions (AV malformation), infectious causes (meningitis, encephalitis), structural lesions (intracranial /brainstem mass lesions, multiple sclerosis, hydrocephalus, syringomyelia)
  - Seizure disorder
  - Diaphragmatic irritation (tumors, pericarditis, eventration, splenomegaly, hepatomegaly, peritonitis)
  - Irritation of the tympanic membrane
  - Nerve irritation: pharyngitis, laryngitis, neck tumors
  - Mediastinal and other thoracic lesions (pneumonia, aortic aneurysm, tuberculosis [TB], myocardial infarction [MI], lung cancer, rib exostoses)
– Esophageal lesions (reflux esophagitis, achalasia, Candida esophagitis, carcinoma, obstruction)
– Gastrointestinal disorders (gastritis, GERD, PUD, distention, cancer)
– Hepatic lesions (hepatitis, hepatoma)
– Pancreatic lesions (pancreatitis, pseudocysts, cancer)
– Inflammatory bowel disease
– Cholelithiasis, cholecystitis
– Prostatic disorders
– Appendicitis
– Postoperative, particularly with abdominal procedures
– Metabolic causes (uremia, hyponatremia, gout, diabetes)
– Drug-induced (dexamethasone, methylprednisolone, anabolic steroids, benzodiazepines, α-methyldopa, propofol)
– Psychogenic causes (hysterical neurosis, grief, malingering)
– Idiopathic

RISK FACTORS

- Overeating
- Consuming carbonated beverages
- Excessive alcohol consumption
- Excitement or emotional stress
- Changes in ambient or gastrointestinal temperature

GENERAL PREVENTION

- Identify and correct relevant underlying cause(s).
- Avoid gastric distention.
- Acupuncture shows promise compared to chronic drug therapy for controlling hiccups (3).

DIAGNOSIS

- Hiccup attacks usually occur at brief intervals and last seconds or minutes. Persistent bouts lasting >48 hours often imply an underlying physical or metabolic disorder.
- Intractable hiccups may occur continuously for months or years (4).
- Hiccups usually have a frequency of 4 to 60 per minute (4).
- Persistent and intractable hiccups warrant further evaluation.

HISTORY

- Severity and duration of hiccup bouts
- Associated medical conditions that could be causative—gastrointestinal, cardiac, neurologic, or pulmonary disorders
- Recent surgery (especially genitourinary)
- Behavioral health history
- Review of medications
- Alcohol and illicit drug use

PHYSICAL EXAM

- Correlate exam with potential etiologies (e.g., rales with pneumonia; organomegaly with
spleen or hepatic disease).
- Examine the ear canal for foreign bodies.
- Head and neck masses and lymphadenopathy
- Complete neurologic exam

**DIFFERENTIAL DIAGNOSIS**
Hiccups are rarely be confused with burping (eructation).

**DIAGNOSTIC TESTS & INTERPRETATION**
- In hiccups lasting >48 hours, if an underlying etiology is suspected, consider condition-specific testing as appropriate (e.g., CBC, electrolytes, BUN, creatinine, LFTs, amylase/lipase, metabolic panel, chest x-ray).
- Fluoroscopy can evaluate hemidiaphragm movement.

**Diagnostic Procedures/Other**
- Upper endoscopy; CT scan (or other imaging) of brain, thorax, abdomen, and pelvis to look for underlying causes
- Head MRI with contrast, lumbar puncture
- The extent of the workup is often in proportion to the duration and severity of the hiccups (2).

**TREATMENT**
- Outpatient (usually)
- Inpatient (if elderly, debilitated, or intractable hiccups)
- Many hiccup treatments are purely anecdotal.

**GENERAL MEASURES**
- Evaluate frequent bouts or persistent hiccups.
- Treat underlying cause when identified (2,4)[C].
  - Dilate esophageal stricture or obstruction.
  - Treat ulcers or reflux disease.
  - Remove hair or foreign body from ear canal.
  - Angostura bitters for alcohol-induced hiccups
  - Catheter stimulation of pharynx for operative and postoperative hiccups
  - Antifungal treatment for Candida esophagitis
  - Correct electrolyte imbalance.
- Medical measures
  - Relieve gastric distention (gastric lavage, nasogastric aspiration, induced vomiting).
  - Cautious counterirritation of the vagus nerve (supraorbital pressure, carotid sinus massage, digital rectal massage)
  - Respiratory center stimulants (breathing 5% CO₂)
  - Behavioral health modification (hypnosis, meditation, paced respirations)
  - Phrenic nerve block or electrical stimulation (or pacing) of the dominant hemidiaphragm
  - Acupuncture
  - Miscellaneous (cardioversion)

**MEDICATION**
First Line
- Physical maneuvers: breath holding, Valsalva maneuver, breathing into a bag, fright, ice water gargles
- Others: swallowing granulated sugar, hard bread, or peanut butter; biting on a lemon, pulling knees to chest or leaning forward to compress chest
- Drug therapy if physical maneuvers have failed or treatment is directed toward a specific cause of hiccups
- Pharmacologic therapy (5)[B]
  - Chlorpromazine (FDA-approved for hiccups): 25 to 50 mg PO/IV TID
  - Metoclopramide: 5 to 10 mg PO QID
  - Baclofen: 5 to 10 mg PO TID (2,4,6)[B]
  - Haloperidol: 2 to 5 mg PO/IM followed by 1 to 2 mg PO TID
  - Phenytoin: 200 to 300 mg PO HS
  - Nifedipine: 10 to 20 mg PO daily to TID
  - Amitriptyline: 10 mg PO TID
  - Viscous lidocaine 2%: 5 mL PO daily to TID
  - Gabapentin (Neurontin): 300 mg PO HS; may increase up to 1,800 mg/day PO in divided doses (4)[B]; 1,200 mg/day PO for 3 days and then 400 mg/day PO for 3 days in patients undergoing stroke rehabilitation or in the palliative care setting where chlorpromazine adverse effects are undesirable (4)[B]
  - Combination of lansoprazole 15 mg PO daily, clonazepam 0.5 mg PO BID, and dimenhydrinate 25 mg PO BID (5)[B]
  - Contraindications: Refer to manufacturer’s literature.
    - Chlorpromazine is not recommended in elderly patient with dementia.
    - Baclofen is not recommended in patients with stroke or other cerebral lesions or in severe renal impairment. Avoid abrupt withdrawal of baclofen.
- Other possible drug therapies (2,5,6)[C]
  - Amantadine, carbidopa and levodopa in Parkinson disease
  - Steroid replacement in Addison disease
  - Antifungal agent in Candida esophagitis
  - Ondansetron in carcinomatosis with vomiting
  - Nefopam (a nonopioid analgesic with antishivering properties related to antihistamines and antiparkinsonian drugs) is available outside the United States in both IV and oral formulations.
  - Olanzapine 10 mg QHS
  - Pregabalin 375 mg/day

ISSUES FOR REFERRAL
For acupuncture or phrenic nerve crush, block, or electrostimulation; cardioversion

SURGERY/OTHER PROCEDURES
- Phrenic nerve crush or transaction or electrostimulation of the dominant diaphragmatic leaflet
- Resection of rib exostoses

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Acupuncture is increasingly used to manage persistent or intractable hiccups, especially in cancer patients (3,4)[A].
Home remedies (2)[C]
- Swallowing a spoonful of sugar
- Sucking on hard candy or swallowing peanut butter
- Holding breath and increasing pressure on diaphragm (Valsalva maneuver)
- Tongue traction
- Lifting the uvula with a cold spoon
- Inducing fright
- Smelling salts
- Rebreathing into a paper (not plastic) bag
- Sipping ice water
- Rubbing a wet cotton-tipped applicator between hard and soft palate for 1 minute

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Most patients can be managed as outpatients; those with severe intractable hiccups may require rehydration, pain control, IV medications, or surgery.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Until hiccups cease

DIET
Avoid gastric distension from overeating, carbonated beverages, and aerophagia.

PATIENT EDUCATION
See “General Measures.”

PROGNOSIS
- Hiccups often cease during sleep.
- Most acute benign hiccup bouts resolve spontaneously or with home remedies.
- Intractable hiccups may last for years or decades.
- Hiccups have persisted despite bilateral phrenic nerve transection.

COMPLICATIONS
- Inability to eat
- Weight loss
- Exhaustion, debility
- Insomnia
- Cardiac arrhythmias
- Wound dehiscence
- Death (rare)

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- R06.6 Hiccough
- F45.8 Other somatoform disorders

**CLINICAL PEARLS**

- Most hiccups resolve spontaneously.
- An organic cause is more likely in men and individuals with intractable hiccups.
- Rule out foreign body in the ear canal as a trigger.
- Baclofen and gabapentin are the only pharmacologic agents proven to be clinically effective.
- Acupuncture may be effective for persistent hiccups.
HIDRADENITIS SUPPURATIVA
Rachel L. Storey, DO ● Cody Homistek, DO ● Christopher A. Zagar, MD, FAAFP

BASICS

DESCRIPTION
- Chronic inflammatory skin disease manifested as recurrent inflammatory nodules, abscesses, sinus tracts, and complex scar formation
- Areas affected are tender, malodorous, often with exudative drainage.
- Common in intertriginous skin regions: axillae, groin, perianal, perineal, inframammary skin
- System affected: skin, psychosocial
- Synonym(s): acne inversa; Verneuil disease; apocrinitis; hidradenitis axillaris

Geriatric Considerations
Rare after menopause

Pediatric Considerations
Rarely occurs before puberty; occurrence in children is associated with premature adrenarche.

Pregnancy Considerations
No Accutane (isotretinoin) or tetracycline treatment during pregnancy. Disease may ease during pregnancy and rebound after parturition.

EPIDEMIOLOGY
- Predominant sex: female > male (3:1)
- African Americans

Incidence
Peak onset during 2nd and 3rd decades of life

Prevalence
0.05–4.10% (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Not fully understood; previously considered a disorder of apocrine glands but more recently thought to be due to a follicular epithelium defect. Deregulation of the local immune system may also play a role.
- Inflammatory disorder of the hair follicle triggered by follicular plugging within apocrine gland–bearing skin
- Hormonally induced ductal keratinocyte proliferation leads to a failure of follicular epithelial shedding, causing follicular occlusion.
- Mechanical stress on skin (intertriginous regions) precipitates follicular rupture and immune response.
- Bacterial involvement is a secondary event.
- Rupture and reepithelialization cause sinus tracts to form.
Genetics
- Familial occurrences suggest single gene transmission (autosomal dominant), but the condition may also be polygenic.
- Estimated 40% of patients have an affected family member.

RISK FACTORS
- Obesity
- Smoking
- Hyperandrogenism
- Lithium may trigger onset of or exacerbate this condition.

GENERAL PREVENTION
- Lose weight if overweight or obese.
- Smoking cessation
- Avoid constrictive clothing/synthetic fabrics, frictional trauma, heat exposure, excessive sweating, shaving, depilation, and deodorants.
- Use of antiseptic soaps

COMMONLY ASSOCIATED CONDITIONS
- Acne vulgaris, acne conglobate
- Perifolliculitis capitis abscedens et suffodiens (dissecting cellulitis of scalp)
- Pilonidal disease
- Metabolic syndrome/obesity
- Polycystic ovary syndrome (PCOS) and androgen dysfunction
- Thyroid disease
- Arthritis and spondyloarthritis (seronegative)
- Irritable bowel disease (Crohn disease)
- Squamous cell carcinoma
- PAPASH syndrome (pyogenic arthritis, pyoderma gangrenosum, acne, and suppurative hidradenitis)

DIAGNOSIS

HISTORY
- Diagnostic criteria adopted by the 2nd International Conference on Hidradenitis Suppurativa, 2009 (2)
- All three criteria (morphology, location, progression) must be present for diagnosis:
  - Typical lesions: painful nodules, abscesses, draining sinus, bridged scars, and “tombstone” double-ended pseudocomedones in secondary lesions
  - Typical topography: axillae, groins, perineal and perianal region, buttocks, infra- and intermammary folds
  - Chronicity and recurrences, commonly refractory to initial treatments

PHYSICAL EXAM
- Tender dome-shaped nodules 0.5 to 3.0 cm in size are present.
  - Location corresponds with the distribution of apocrine-related mammary tissue and terminal hair follicles dependent on low androgen concentrations.
Sites ordered by frequency of occurrence: axillary, inguinal, perianal and perineal, mammary and inframammary, buttock, pubic region, chest, scalp, retroauricular, eyelid. Large lesions are often fluctuant; comedones may be present.

- Possible malodororous discharge
- Hurley clinical staging system
  - **Stage I**: nodule/abscess formation without sinus tracts or scarring
  - **Stage II**: more than one lesion widely spaced with tract and scar formation
  - **Stage III**: diffuse, multiple interconnected tracts and abscesses with scarring
- Sartorius clinical staging system (points attributed)
  - Anatomic region involved
  - Quantity and quality of lesions
  - Distance between lesions
  - Presence or absence of normal skin between lesions

**DIFFERENTIAL DIAGNOSIS**
- Acne vulgaris, conglobate
- Furunculosis/carbuncles
- Infected Bartholin or sebaceous cysts
- Lymphadenopathy/lymphadenitis
- Cutaneous Langerhans cell histiocytosis
- Actinomycosis
- Granuloma inguinale
- Lymphogranuloma venereum
- Apocrine nevus
- Crohn disease with anogenital fistula(s) (may coexist with hidradenitis suppurativa)
- Fox-Fordyce disease

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Cultures of skin or aspirates of boils are most commonly negative. When positive, cultures are often polymicrobial and commonly grow *Staphylococcus aureus* and *Staphylococcus epidermidis*.
- Lesion biopsy usually unnecessary; useful to rule out other disorders such as squamous cell carcinoma
- May note increased erythrocyte sedimentation rate (ESR), leukocytosis, decreased serum iron, normocytic anemia, or changes in serum electrophoresis pattern

**Follow-Up Tests & Special Considerations**
- Consider biopsy of concerning lesions due to increased risk of squamous cell carcinoma.
- If the patient is female, overweight, and/or hirsute, consider evaluating the following:
  - Dehydroepiandrosterone sulfate
  - Testosterone: total and free
  - Sex hormone–binding globulin
  - Progesterone

**Diagnostic Procedures/Other**
- Incision and drainage, culture and biopsy
- Ultrasound may be useful in planning an excision to identify the full extent of sinus tracts.
Test Interpretation
- Dermis shows granulomatous inflammation and inflammatory cells, giant cells, sinus tracts, subcutaneous abscesses, and extensive fibrosis.
- Hair follicular dilatation and occlusion by keratinized stratified squamous epithelium

TREATMENT
Despite the prevalence of this condition, most trials have been small and underpowered. Evidence is therefore generally of poor quality (3)[A]. Treatment goals: Reduce extent of disease, prevent new lesions, remove chronic disease, and limit scar formation.
- Conservative treatment includes all items under “General Prevention,” plus use of warm compresses, sitz baths, topical antiseptics for inflamed lesions, and nonopioid analgesics.
- Weight loss and smoking cessation result in marked improvement (1).
- Corticosteroids, isotretinoin, and zinc gluconate
- For stages I and II, attempt medical treatment.
- Short medical trial may be appropriate in stage III prior to moving on to surgical therapies.
- Only FDA-approved medication for this condition is adalimumab. Other biologics may be effective. No medications are curative; relapse is almost inevitable, but the disease may be controlled. Usually must fail other treatments before starting biologics. They can be a costly option.

GENERAL MEASURES
- Education and psychosocial support
- Appropriate hygiene including avoidance of shearing stress to skin (light clothing), daily cleansing with antibacterial soap
- Diet: Avoid dairy, high glycemic loads.
- Symptomatic treatment for acute lesions
- Improve environmental factors that cause follicular blockage (see “General Prevention”).
- Smoking cessation and weight loss

MEDICATION
First Line
- Stage I disease: Consider either systemic or topical antibiotics.
  - Topical antibiotics (clindamycin was studied in clinical trials) (1)[B]
    - Clindamycin 0.1% solution BID for 12 weeks with or without benzoyl peroxide 5–10% solution
    - Chlorhexidine 4% solution
  - Systemic antibiotics (initial 7- to 10-day course)
    - Tetracycline 500 mg BID
    - Doxycycline 100 mg q12h
    - Augmentin 875 mg q8–12h
  - Clindamycin 300 mg BID (4)[B]
    - Intralesion corticosteroids: limited evidence; possible reduction in pain, erythema, edema, and lesion size (1). (triamcinolone acetonide 10 mg/mL usually 0.2 to 2.0 mL injection)
- Stages II and III disease
  - Address overlying bacterial infection with broad-spectrum coverage. Base antibiotic
selection on disease location and characteristics; best evidence for antibiotic treatment with combinations of clindamycin and rifampicin, or ertapenem followed by combination rifampicin, moxifloxacin, and metronidazole for 6 months (1)[A]

- Minor surgical procedures (punch débridement, local unroofing) to treat individual lesions or sinus tracts
- Other modalities (rarely used)
  - Hormonal therapy: antiandrogenic therapy such as cyproterone acetate (may not be available in the United States), estrogen/norgestrel oral contraceptive, finasteride (5 mg daily)

**Second Line**

- Dapsone 50 to 150 mg daily
- Metformin: significant reduction in Sartorius score
- Oral retinoids (isotretinoin): poor efficacy, limited therapeutic effect
- TNF-α inhibitors:
  - Adalimumab 40 mg weekly (a high dose) produces statistically significant differences versus placebo in treated patients, but clinical effect size is small (Cochrane) (1)[A], and long-term safety is unknown (5)[A].
  - Infliximab: A majority of patients in the treatment group had a 50% or greater decrease in disease, improving quality of life (5)[A].
  - Etanercept: no difference versus placebo

**ISSUES FOR REFERRAL**

- Lack of response to treatment, stages II and III disease, or concern for malignancy (squamous cell carcinoma) is a reason to refer for surgical excision or radiation/laser treatment (stage II).
- If significant psychosocial stress exists secondary to disease, refer for stress management or psychiatric evaluation.
- Suspicion of hyperandrogenic states (e.g., PCOS) should prompt investigation or referral.
- Severe perianal/perivulvar disease or otherwise very extensive disease may prompt referral to plastic surgeon or reconstructive urologist.

**SURGERY/OTHER PROCEDURES**

- Important mode of treatment; necessary if wanting to permanently remove tunnels and scarring
- Could be used in conjunction with antibiotics or if first-line therapy fails
- Various surgical approaches have been used for stages II and III disease.
  - Incision and drainage: necessary to treat acute flare-ups when abscess is present
  - Deroofing of sinus tracts and skin tissue–sparing excision with electrosurgical peeling (STEEP) allow for healing by secondary intention. Recurrences remain common but usually are smaller than original lesions.
  - Wide full-thickness excision with healing by granulation or flap placement is the most definitive treatment and rarely has local recurrence if all sinus tracts are excised with a clear 1- to 2-cm margin. Rates of local recurrence (within 3 to 72 months): axillary (3%), perianal (0%), inguinoperineal (37%), submammary (50%)
- Laser therapy for Hurley stages I and II disease (rarely used); no consensus on the benefit
  - Monthly treatments with neodymium-doped yttrium aluminum garnet (Nd:YAG) laser for 3 to 4 months
  - CO₂ laser ablation with healing by secondary intention
- Cryotherapy and photodynamic therapy have shown variable results; they are not routinely recommended.
- Potential role for combined therapy consisting of radical resection plus biologic in advanced cases

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Follow up monthly or sooner to evaluate progress and to assist with symptom management.

**DIET**
- Avoid dairy and high glycemic loads.
- Healthy diet that promotes weight loss
- May benefit from zinc supplementation

**PATIENT EDUCATION**
- Severity can range from only two to three papules per year to extensive draining sinus tracts.
- Medications are temporizing measures, rarely curative. Attempts at local surgical “cures” do not affect recurrence at other sites.
- Smoking cessation and weight loss can improve symptoms significantly.
- Hidradenitis Suppurativa Foundation: [www.hs-foundation.org](http://www.hs-foundation.org)

**PROGNOSIS**
- Individual lesions heal slowly in 10 to 30 days.
- Recurrences may last for several years.
- Relentlessly progressive scarring and sinus tracts are likely with severe disease.
- Radical wide-area excision, with removal of all hair-bearing skin in the affected area, shows the greatest chance for cure.
- Increased all-cause mortality

**COMPLICATIONS**
- Contracture and stricturing of the skin after extensive abscess rupture, scarring, and healing; or at sites of surgical excisions
- Lymphatic obstruction, lymphedema
- Psychosocial: anxiety, malaise, depression, self-injury
- Anemia, amyloidosis, and hypoproteinemia (due to chronic suppuration)
- Lumbosacral epidural abscess, sacral bacterial osteomyelitis
- Squamous cell carcinoma may develop in indolent sinus tracts.
- Disseminated infection or septicemia (rare)
- Urethral, rectal, or bladder fistula (rare)

**REFERENCES**

ADDITIONAL READING

CODES

ICD10
L73.2 Hidradenitis suppurativa

CLINICAL PEARLS

- Chronic inflammatory disease of the skin, often difficult to control with behavior changes and medication alone
- First-line treatment for mild disease is topical and/or systemic antibiotics.
- For patients with refractory or severe disease, wide local excision provides the only chance at a cure. Success rates depend on the location and extent of excision.
- This is a difficult to treat disease that can greatly affect the patient’s quality of life.
HIRSUTISM
Natasha S. Kadakia, DO • Ruchita Patel, DO

BASICS

DESCRIPTION
- Presence of excessive terminal (coarse, pigmented) hair of body and face, in a male pattern
- May be present in normal adults as an ethnic characteristic or may develop as a result of androgen excess
- Often seen in polycystic ovary syndrome (PCOS), which is characterized by hirsutism, acne, menstrual irregularities, and obesity
- System(s) affected: dermatologic, endocrine, metabolic, reproductive

EPIDEMIOLOGY

Prevalence
5–10% of reproductive age women

ETIOLOGY AND PATHOPHYSIOLOGY

- Hirsutism is due to increased androgenic (male) hormones, either from increased peripheral binding (idiopathic) or increased production from the ovaries, adrenals, or body fat.
- Exogenous medications can also cause hirsutism.
- Can be a symptom of multiple etiologies such as clinical evidence of PCOS, androgen secreting tumors, virilizing disorders, or androgenic medication use.

Genetics
Multifactorial

RISK FACTORS
- Family history
- Ethnicity—increased in Ashkenazi Jews and Mediterranean backgrounds
- Anovulation
- Obesity

GENERAL PREVENTION

Women with late-onset congenital adrenal hyperplasia (CAH) should be counseled that they may be carriers for the severe early-onset childhood disease.

COMMONLY ASSOCIATED CONDITIONS
- PCOS: the most common cause of premenopausal hirsutism (1)
- Insulin resistance, common
- Prolonged amenorrhea and anovulation, common
- Emotional distress and depression, common
- Acne, common
- Central obesity
- Hypothyroidism/hyperthyroidism, rare
- Hyperprolactinemia, rare
- Risk for endometrial hyperplasia or carcinoma, rare
- Virilization (rapid onset, clitoromegaly, balding, deepening voice) (2)
- Cushing syndrome: characterized by moon facies, striae, hypertension, rare
- Acromegaly, rare
- Vitamin D deficiency

**DIAGNOSIS**

**HISTORY**
- Severity, time course, and age of onset of hirsutism
- Weight
- Psychosocial impact on patient
- Menstrual and fertility history, anovulation (defined as ovulatory cycle >35 days)
- Severe acne, especially if treatment resistant
- Presence of virilization
- Medication history: Look for use of valproic acid, testosterone, danazol, glucocorticoids, topical androgen use by partner, and athletic performance drugs.
- The presence of galactorrhea

**PHYSICAL EXAM**
- Increased hair growth in premenopausal women, particularly over the chin, neck, sideburns, lower back, sternum, abdomen, shoulders, buttocks, perineal area, and inner thighs
- Check skin for acne, striae, acanthosis nigricans (velvety black skin in the axillae or neck).
- Virilization: Deep voice, male pattern balding, increased muscle mass, and clitoromegaly indicate risk of tumor.
- The Ferriman-Gallwey scale (an instrument that rates hair growth in nine areas on a scale of 0 to 4, with >8 being positive) may be used for diagnosis but underrates patient’s perception of hirsutism and altered by previous cosmetic treatment. Scores between 8 and 15 are considered to be mild hirsutism, 16 to 25 moderate, and >25 severe (1,2).

**DIFFERENTIAL DIAGNOSIS**
- PCOS (72–82%)—irregular menses, elevated androgens, polycystic ovaries on US, infertility, insulin resistance
- Idiopathic hyperandrogenemia (6–15%)—hirsutism with normal ovaries on US, elevated androgen levels, no other explainable cause
- Idiopathic hirsutism (4–7%)—hirsutism with normal menses, androgen levels, and ovaries on ultrasonography, no other explainable cause
- Late-onset CAH (2–4%)—a genetic enzyme deficiency associated with more severe and earlier onset hirsutism in amenorrheic patients; presents in adolescence with severe hirsutism and irregular menses
- Androgen-secreting tumor (0.2%)—ovaries (benign or malignant) or adrenals (commonly malignant); have rapid onset, virilization, resistance to treatment
- Ovarian hyperthecosis—increase in testosterone by theca cells. Gradual onset of hirsutism, frank virilization; mostly affects postmenopausal women
- Thyroid dysfunction
- Hyperprolactinemia if accompanied by galactorrhea or amenorrhea
- Rare endocrine disorders—Cushing, acromegaly
DIAGNOSTIC TESTS & INTERPRETATION

- Testing for elevated androgen levels in all women with an abnormal hirsutism score. Guidelines recommend screening hyperandrogenemic women for NCCAH due to 21-hydroxylation deficiency by measuring early morning 17-hydroxyprogesterone levels (2).
- PCOS is diagnosed by having two out of three signs: menstrual dysfunction, clinical or biochemical hyperandrogenemia, polycystic ovaries on US (2)[C].
- Lab testing is performed to rule out underlying tumor and pituitary diseases, which are rare.

Initial Tests (lab, imaging)

- Basic workup of moderate hirsutism is a total testosterone level +/- thyroid screen (TSH) (1)[C].
- Testosterone: Random total testosterone level is usually sufficient.
- Normal upper limit for serum total testosterone in adult women is approximately 40 to 60 ng/dL (1.4 to 2.1 nmol/L). Patients who have clinical features consistent with PCOS but have normal total testosterone should have repeat testing, preferably an early morning serum free testosterone level calculated from sex hormone-binding globulin (SHBG). A morning free testosterone is 50% more sensitive (1,3).
- If testosterone is >150 (some use 200) ng/dL, consider ovarian or adrenal tumor (2,4). Testosterone is made by both the ovaries and adrenals, so both areas should be imaged. US is best for the ovaries, and CT is best for the adrenals.
- The workup for PCOS recommended by the American College of Obstetricians and Gynecologists (ACOG) includes the above plus:
  - Screening for metabolic syndrome with a fasting and 2-hour glucose after 75-g glucose load, lipid panel, waist circumference, and blood pressure (4)[C]
- Ovarian US to look for polycystic ovaries
- If the patient is amenorrheic, check prolactin, follicle-stimulating hormone (FSH), luteinizing hormone (LH), TSH, and a pregnancy test (5)[C]. An LH/FSH ratio >2 indicates PCOS.

Follow-Up Tests & Special Considerations

- 17α-Hydroxyprogesterone (17α-OHP)
  - Elevations of 17α-OHP (>300 ng/dl) can indicate late-onset CAH.
  - Consider in patients with onset in early adolescence or high-risk group (Ashkenazi Jews) (2)[C].
  - If elevated, order corticotropin stimulation test.
- If prolactin level is high, MRI the pituitary.
- If PCOS is diagnosed, ACOG recommends screening for dyslipidemia and diabetes mellitus type 2 (4)[C].
- New studies show an inverse correlation between vitamin D levels and insulin resistance in women with PCOS. Screening women who are at risk of vitamin D deficiency and supplementation with vitamin D could be considered (6)[B].
- Dehydroepiandrosterone sulfate (DHEA-S) is no longer recommended routinely but should be checked in virilization (5)[C].
  - Levels >700 mcg/dl may indicate adrenal tumor.

TREATMENT
GENERAL MEASURES

- Treatment in mild hirsutism depends on patient preference and psychosocial effect.
- If patient desires pregnancy, induction of ovulation may be necessary.
- Provide contraception, as needed.
- Encourage patient to maintain ideal weight with lifestyle modification. A calorie-restricted diet is recommended in all overweight patients with PCOS. Weight loss has positive effects on fertility, metabolic profile, and may improve hirsutism (5).
- Treat accompanying acne.

MEDICATION

First Line

- Treatment goal is to decrease new hair growth and improve metabolic disorders.
- Direct hair removal or pharmacologic therapy is recommended for mild hirsutism (2)[B].
- Oral contraceptives are first line to manage menstrual abnormalities and hirsutism/acne (3)[A]; they will suppress ovarian androgen production and increase SHBG, improve metabolic syndrome, and slow but not reverse hair growth.
  - Doses of 20 to 35 μg ethinyl estradiol effectively decrease ovarian androgen production. Those containing the progestins, norgestimate, desogestrel, or drospirenone have more androgen-blocking effects, but desogestrel and drospirenone are associated with more deep venous thrombosis, especially in severely obese patients (3,4)[C].
  - They take 6 months to show effect and are continued for years.
  - Oral preparations, compared to vaginal or transdermal, are better at controlling hirsutism and acne; by passing through the liver, they induce SHBG production (1).
- Progesterone (depot or intermittent oral) can be used if estrogens are contraindicated (4).
- Eflornithine (Vaniqa) HCl cream: Apply BID at least 8 hours apart; reduces facial hair in 40% of women (must be used indefinitely to prevent regrowth); only FDA-approved hirsutism treatment
  - Two clinical trials have been shown to have a more rapid response in regards to preventing hair regrowth when undergoing laser therapy with eflornithine cream.
- Combination oral contraceptives and antiandrogen is contraindicated first line unless those with severe hirsutism and significant emotional distress or no success with oral contraceptives alone (failure of therapy after 6 months) (2)[B].

Second Line

- Antiandrogenic drugs will further reduce hirsutism to 15–25%. Usually begun 6 months after first-line therapy if results are suboptimal. Must be used in combination with oral contraceptives to prevent menorrhagia and potential fetal toxicity. All should be avoided in pregnancy (2,5)[C].
  - Spironolactone, 50 to 200 mg/day: Onset of action is slow; use with oral contraceptives to prevent menorrhagia. Watch for hyperkalemia, especially with drospirenone-containing oral contraceptive pill (OCP) (Yasmin); avoid use in pregnancy (7)[B]
  - Finasteride: 5 mg/day decreases androgen binding; not approved by FDA. Use with contraception (pregnancy Category X).
  - Cyproterone, not available in the United States: 12.5 to 100.0 mg/day for days 5 to 15 of cycle combined with ethinyl estradiol 20 to 50 μg for days 5 to 25 of cycle
  - Flutamide is not recommended due to potential hepatotoxicity (2)[C].
  - Topical antiandrogen therapy is not recommended.
It is suggested against using insulin-lowering drugs as the sole indication of treating hirsutism (2).

**Steroids:** used in late-onset CAH
- Dexamethasone: 2 mg/day

**Cosmetic treatment:** includes many methods of hair removal
- Temporary: shaving, chemical depilation, plucking, waxing
- Permanent: Laser epilation and photoepilation are preferred to electrolysis (4)[C].
- If hair removal therapy is chosen, pharmacologic therapy is suggested to minimize hair regrowth (2).
- For direct hair removal, electrolysis rather than photoepilation is recommended in women with blonde or white hair (6).

**Pregnancy Considerations**
- May have related infertility. Offer intervention, if desired.
- As hormone balance improves, fertility may increase; provide contraception, as needed.
- Several medications used for treatment are contraindicated in pregnancy.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Several herbals including spearmint tea, saw palmetto, licorice, fennel, and soy have been shown in small (<50 people) and short (<12 weeks) studies to decrease hair size or lower androgen levels (5)[C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
No special activity

**Patient Monitoring**
Monitor for known side effects of medications.

**DIET**
Diet consisting of low-calorie, low-glycemic index foods improve fertility in obese PCOS patients with anovulatory infertility.

**PATIENT EDUCATION**
- Hormonal treatment stops further hair growth and will improve but not reverse present hair.
  - Treatment takes 6 months to take effect and may need to be lifelong.
- Cosmetic measures may be needed for the already present hair (see above).

**PROGNOSIS**
- Good (with long-term therapy) for halting further hair growth
- Moderate to poor for reversing current hair growth

**COMPLICATIONS**
- If PCOS is present, dysfunctional uterine bleeding may lead to anemia.
- If PCOS is present, anovulation may increase endometrial hyperplasia and uterine cancer risk.
- Androgenic excess may adversely affect lipid status, cardiac risk, and bone density.
- Poor self-image

SEE ALSO

Acne Vulgaris; Infertility; Polycystic Ovarian Syndrome (PCOS)

CODES

ICD10
- L68.0 Hirsutism
- E28.2 Polycystic ovarian syndrome

CLINICAL PEARLS

- PCOS is the most common cause of hirsutism (diagnosed with two out of three: menstrual dysfunction, clinical or biochemical hyperandrogenemia, polycystic ovaries on US).
- Diagnosis is based on androgen level in all women with abnormal hirsutism score; total testosterone and TSH for initial testing
- Virilization (clitoromegaly, balding, deepening voice): Suspect if testosterone >150 ng/dL; look for adrenal and ovarian tumor.
Lifestyle modification and OCPs are first-line therapy for hirsutism, menstrual irregularities, and acne.
HIV/AIDS
Carol H. Hungerford, DO  ●  Pamela R. Hughes, MD

BASICS

DESCRIPTION
- HIV is a retrovirus (subgroup lentivirus) that integrates into CD4 T lymphocytes, altering cell-mediated immunity and causing cell death, severe immunodeficiency, opportunistic infections, and malignancies if not treated.
- The natural history of untreated HIV infection includes viral transmission, acute retroviral syndrome, recovery and seroconversion, asymptomatic chronic HIV infection, and symptomatic HIV infection or AIDS.
- Without treatment, the average patient progresses to AIDS ~10 years after acquiring the virus.
- HIV-infected persons with CD4 <200 cells/mm$^3$ or with AIDS-defining illnesses are categorized as persons living with AIDS.

EPIDEMIOLOGY

Incidence
In the United States, HIV incidence has decreased 9% since 2010. There were approximately 39,000 new cases in 2017. There were approximately 1.8 million new cases of HIV worldwide in 2017 (1).

Prevalence
- ~1.1 million persons in the United States are living with HIV, ~15% are not aware they are infected (1).
- Worldwide, >35 million people are living with HIV. >75% are in sub-Saharan Africa.
- In 2017, ~1 million people died from AIDS (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- HIV primarily infects CD4+ cells. HIV is a single-stranded, positive-sense, enveloped RNA virus. After entering target cells, viral RNA is transcribed to DNA (through reverse transcription), imported to the host cell nucleus and incorporated into host DNA. The virus can become latent or produce new viral RNA with proteins that are released to infect other CD4+ cells. Host CD8+ cells are activated as part of the seroconversion response.
- There are two types of HIV. HIV-1 was first described and is more virulent, causing the majority of HIV infections worldwide. HIV-2 is less infective and seen primarily in West Africa.

RISK FACTORS
- Sexual activity (>90% of transmission): Ulcerative urogenital lesions promote transmission (1).
- Injection drug use
- Children of HIV-infected women
  - Maternal HIV-1 RNA level predicts transmission.
  - HIV can also be transmitted in breast milk. HIV+ women should not breastfeed their infants unless there is no other alternative. In this case, consider antiretroviral therapy (ART) (2).
Recipients of blood products prior to 1985
Occupational exposure (health care workers)

GENERAL PREVENTION
- Avoid unprotected, high-risk sex and intravenous drug use, particularly with shared needles.
- Preexposure prophylaxis (PrEP) is recommended by World Health Organization and U.S. Preventive Services Task Force (USPSTF) for persons at high risk of acquiring HIV.
- General guidelines for PrEP: (i) exclude acute or chronic HIV infection before initiating therapy, (ii) repeat HIV testing every 3 months during therapy, (iii) renal function testing at baseline and every 6 months
- Postexposure prophylaxis (PEP) should be started within 72 hours of exposure and continued for 28 days with a three-drug regimen 1.
- USPSTF recommends routine screening for all patients 15–65 years old. Patients who are at increased risk should be screened at any age.

COMMONLY ASSOCIATED CONDITIONS
- Syphilis is more aggressive in HIV-infected persons.
- Tuberculosis (TB) is coepidemic with HIV; test all patients for TB. Dually infected patients (TB and HIV) have 100 times greater risk of developing active TB.
- Patients coinfected with hepatitis B or hepatitis C have a more rapid progression to cirrhosis.
- Increased risk for cervical cancer, lymphoma, and skin malignancies

DIAGNOSIS
- Acute retroviral syndrome: CD4 lymphocyte count declines with increase in viral load 1 to 4 weeks after transmission; confirmed by high-HIV RNA in the absence of HIV antibody
- Acute retroviral syndrome presents as a mononucleosis-like syndrome:
  - Fever, adenopathy, pharyngitis, rash, myalgias/arthralgias
  - Seroconversion: positive HIV antibody 4 weeks to 6 months after exposure
- Clinical latency (asymptomatic): variable duration (average is 8 to 10 years) accompanied by a gradual decline in CD4 cell counts and relatively stable HIV RNA levels (the viral “set point”). Patients often develop persistent generalized lymphadenopathy (>1 cm in size, at ≥2 extrainguinal sites) and may develop fever, weight loss, myalgias, and gastrointestinal problems if unrecognized.
- Associated conditions:
  - Fever or diarrhea >1 month, bacillary angiomatosis, thrush, persistent candidal vulvovaginitis, cervical dysplasia or carcinoma in situ, oral hairy leukoplakia, herpes zoster, idiopathic thrombocytopenic purpura, pelvic inflammatory disease, peripheral neuropathy, or myelopathy.
- AIDS: defined by a CD4 cell count <200, a CD4 cell percentage of total lymphocytes <14%, or an AIDS-related opportunistic infections: Pneumocystis jiroveci (carinii) pneumonia, cryptococcal meningitis, recurrent bacterial pneumonia, candida esophagitis, central nervous system (CNS) toxoplasmosis, TB, non-Hodgkin lymphoma (NHL), progressive multifocal encephalopathy, HIV nephropathy, Kaposi sarcoma, Hodgkin lymphoma, invasive cervical cancer
- Advanced HIV disease: CD4 cell count <50. Most AIDS-related deaths occur at this time. Common late opportunistic infections: cytomegalovirus (CMV) disease (retinitis, colitis) or
HISTORY
- Complete medical history, including risk exposures, sexual, social and occupational histories, intravenous drug use, receipt of blood products (prior to 1985 in U.S.).
- Review of systems: fever, chills, night sweats, weight loss, fatigue, adenopathy, diarrhea, oral sores, odynophagia (esophageal candidiasis), cough, shortness of breath and dyspnea on exertion (early P. jiroveci pneumonia), sinusitis, visual changes (CMV retinitis), neurologic symptoms (CNS infection, malignancy, or dementia), skin rash
- Review immunization record.

PHYSICAL EXAM
- There are no physical examination findings that are specific to HIV infection.
- Focus on weight (weight loss is common), skin, retinal exam, oropharynx, lymph nodes (generalized lymphadenopathy is common), liver, spleen, mental status, neurologic, genital, and rectal examinations.

DIFFERENTIAL DIAGNOSIS
Burkitt lymphoma, candidiasis, CMV, coccidioidomycosis, cryptococcus, Epstein-Barr virus, herpes simplex, influenza, lymphoma, mononucleosis, TB, toxoplasmosis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Screening: Rapid oral test is Food and Drug Administration (FDA) approved. Two FDA-approved home testing kits are available.
  - Fourth-generation HIV testing combines antibody/antigen immunoassay for HIV-1/HIV-2
  - Can be positive within 2 to 3 weeks of exposure
  - Is considered a confirmatory test. Western blot confirmation is no longer recommended.
- Obtain HIV RNA if acute HIV infection is suspected using quantitative polymerase chain reaction; detects infection within 12 days of exposure
- CD4 cell count and percentage
- HIV RNA viral load
- CBC with differential; lipid levels
- Serologies: hepatitis A/B/C, syphilis
- Screen for sexually transmitted infection (chlamydia, gonorrhea, syphilis).
- Cervical cytology
- Purified protein derivative (PPD) or interferon-γ release assay (IGRA) to screen for latent TB infection; chest x-ray (CXR) if pulmonary symptoms or positive PPD
- HLAB*5701 testing if abacavir planned for treatment
- Genotypic tests for resistance to antiretrovirals for patients with pretreatment HIV RNA >1,000 copies/mL; transmitted resistance to at least one drug seen in 6–16% of patients
- Tropism assay if considering CCR5 antagonist

TREATMENT
- Initiate ART in patients meeting eligibility requirements. Select/change regimens based on
resistance testing.

- Consider dosing frequency, pill burden, adverse toxic effect profiles, comorbidities, and drug interactions.

- Pregnancy, AIDS-defining conditions, acute opportunistic infections, CD4 <200, HIV-associated nephropathy, acute/early infection, HIV/HBV co-infection, HIV/HCV co-infection, rapidly declining CD4 counts (>100 cells/mm$^3$ per year), and high viral loads (>100,000 copies/mL) increase urgency for immediate therapy (3)[A].

- In women of childbearing age, use ART regimen that decreases viral load with minimal teratogenicity (2)[A].

- Genotypic testing is recommended to guide therapy in patients who are naive to ART.

- Tenofovir/emtricitabine (Truvada) 300 mg/200 mg PO daily is FDA approved for PrEP in adults at high risk (4)[A].

### GENERAL MEASURES

- The goal of ART is to reduce viral load (below limits of detection) and delay immune suppression. Viral load is the most important indicator of response to ART.

- Assess drug resistance before starting ART (3).

- Assess substance abuse, economic factors (unstable housing, food insecurity), social support, mental illness, comorbidities, high-risk behaviors, and factors known to impair adherence and promote transmission.

- Prophylactic antimicrobial agents and vaccines:
  - P. jiroveci prophylaxis: trimethoprim/sulfamethoxazole (TMP-SMX) if CD4 <200 cells/mm$^3$, prior P. jiroveci, thrush, or unexplained fever for >2 weeks
  - Mycobacterium tuberculosis: Treat for latent TB if positive PPD or positive IGRA without prior prophylaxis or treatment, with negative CXR, recent TB contact, or history of inadequately treated TB that healed.
  - Toxoplasma gondii prophylaxis: 33% per year risk of infection in untreated patients with CD4 <100 cells/mm$^3$; prophylaxis: TMP-SMX 1 DS tab daily
  - M. avium complex prophylaxis: 20–40% risk with CD4 <50 and no ART. Azithromycin 1,200 mg PO weekly is preferred prophylaxis.
  - Streptococcus pneumoniae: 50 to 100 times increased risk of invasive infection compared with general population; Prevnar and pneumovax at least 8 weeks apart, every 5 years
  - Influenza vaccine annually (no live vaccine)
  - Hepatitis A and B vaccines
  - At least 3 Tdap vaccines in lifetime and Td vaccination every 10 years.

### MEDICATION

- Recommended regimens for ART naïve (3)[A]
  - Integrase strand transfer inhibitor-based regimens:
    - Dolutegravir/abacavir/lamivudine (50 mg/600 mg/300 mg PO daily)—only for patients who are HLA-B*5701 negative
    - Bictegravir/tenofovir/emtricitabine (50 mg/25 mg/200 mg PO daily)
    - Dolutegravir (50 mg PO daily) plus tenofovir disoproxil fumarate/emtricitabine (300 mg/200 mg PO daily)
    - Elvitegravir/cobicistat/tenofovir/emtricitabine (150 mg/150 mg/300 mg/200 mg PO daily) —only for patients with pre-ART CrCl >70 mL/min
    - Raltegravir (400 mg PO BID) plus tenofovir/emtricitabine (300 mg/200 mg PO daily)
– Protease inhibitor-based regimen:
  o Darunavir and ritonavir (800 mg PO daily and 100 mg PO daily) plus
tenofovir/emtricitabine (300 mg/200 mg PO daily)

Drug failure: Before selecting regimen, review clinical symptoms, history of ART, and
adherence. Perform resistance testing.

ART, especially the protease inhibitors, have interactions with other medications, such as
antacids, steroids, contraceptives.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

● HIV RNA (viral load) 2 to 8 weeks after starting therapy and repeated every 3 to 6 months
  until suppressed (3).
● Monitor HIV RNA, CD4, and CBC every 3 to 4 months for first 2 years of ART or if the CD4
count is <300 cells/mm³ (3).
● Space CD4 monitoring to 12 months if suppressed viral load and CD4 >300 cells/mm³.
● Monitor HIV RNA and CBC every 6 months (3).
● Annual HIV RNA and CD4 count once viral load undetectable and stable.
● Once viral load has been suppressed consistently for >2 years and CD4 cell counts are
  consistently >500/µL, monitoring CD4 cell counts is optional unless virologic failure occurs
  (or there are intercurrent immunosuppressive treatments or conditions).
● Confirm HIV-1 RNA level is >50 copies/mL within 4 weeks of medication management
  decisions.
● Annual fasting lipids and fasting glucose; basic metabolic panel, AST/ALT, total/direct
  bilirubin every 6 to 12 months (3).
● Annual cervical cytology annually (regardless of age) until three negative screens and then
every 3 years.
● Pregnancy test in women of childbearing age (3).
● Urinalysis every 6 to 12 months or as clinically indicated (3).
● Hepatitis C as clinically indicated (3).

DIET

● Encourage good nutrition; avoid raw eggs and unpasteurized dairy products.
● Discuss unknown and potentially harmful effects of supplement use including drug–drug
  interactions.

PATIENT EDUCATION

Provide nonjudgmental, sex-positive prevention counseling, reviewing high-risk behaviors and
viral transmission. American Foundation for AIDS Research: 212-719-0033 (new treatments and
research) https://aidsinfo.nih.gov/

PROGNOSIS

● Untreated HIV infection leading to the diagnosis of AIDS has an associated life expectancy of
  about 3 years, and if the patient has an opportunistic infection, the life expectancy is about 1
  year.
AIDS-defining opportunistic infections usually do not develop until CD4 <200.
Adherence failure—not drug resistance—is the most common cause of treatment failure.

COMPLICATIONS
- Immunodeficiency
- Opportunistic infections
- Neurologic complications:
  - AIDS dementia complex (ADC), cryptococcal meningitis, CMV encephalitis, progressive multifocal leukoencephalopathy (PML), neurosyphilis, herpes encephalitis, toxoplasma encephalitis, vacuolar myelopathy, and psychological and neuropsychiatric disorders (5).
- Respiratory complications such as acute bronchitis, bacterial pneumonia, P. carinii pneumonia with CD4 <200 cells/mm³ and M. avium.
- Malignancy, including lymphoma and cervical or anal cancer.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- Z21 Asymptomatic human immunodeficiency virus infection status
- B20 Human immunodeficiency virus [HIV] disease
- R75 Inconclusive laboratory evidence of human immunodef virus

CLINICAL PEARLS
- Acute HIV seroconversion illness mimics mononucleosis and is characterized by fever, sore throat, adenopathy, myalgias, and rash.
- Transmitted drug resistance is increasing. Evaluate for resistance prior to initiating ART.
- Provide necessary vaccinations and prophylactic antibiotics to HIV+ patients based on clinical history and CD4 count.
- Discuss prevention strategies, including PrEP, with individuals who are at high risk of HIV infection.
- Consider HIV testing in at-risk patients reporting unintended weight loss, fatigue, night sweats, or rash.
HODGKIN LYMPHOMA
John L. Reagan, MD

BASICS

DESCRIPTION
Historical background:
- Described in 1832 by Thomas Hodgkin in “On some morbid appearance of the absorbent glands and spleen”
- First neoplasm to be (i) defined by cytologic grounds based on presence of Reed-Sternberg (RS) cells, (ii) clinically staged neoplastic disease, and (iii) treated with chemotherapy and/or radiotherapy
- Neoplastic RS cells of monoclonal lymphoid B-cell origin within inflammatory background of lymphocytes (T-helper type 2 and regulatory T cells), eosinophils, histiocytes, and plasma cells
- Two subtypes: classic Hodgkin lymphoma (CHL, 95% of cases) and nodular lymphocyte predominant Hodgkin lymphoma (NLPHL, 3–8% of cases)
  - NLPHL: B cells, neoplastic luteinizing hormone (LH) cells with multilobulated nuclei, small nucleoli, and popcorn-like appearance
  - CHL histologic subdivisions: nodular sclerosing (60%), mixed cellularity (30%), lymphocyte depleted (<10%), lymphocyte rich (<10%)
- Frequency of lymph node involvement: cervical > mediastinal > axillary > paraaortic

EPIDEMIOLOGY
- Incidence: 2.6/100,000/year
- Predominance: 8% of lymphoid malignancies
- Typically diagnosed at age 20 to 34 years with median age 39 years at diagnosis given decreasing bimodal age distribution
- 1.3:1 male-to-female ratio

Geriatric Considerations
Poorer prognosis if present at ≥60 years:
- Less likely to tolerate intensive chemotherapy
- Less likely to be included in clinical trial

Pediatric Considerations
Young females (<30 years of age) treated with thoracic radiation are at high risk for breast cancer, and early breast cancer screening is recommended.

Pregnancy Considerations
- Abdominal ultrasonography to detect subdiaphragmatic disease
- Treatment:
  - Delay until after delivery if asymptomatic and early stage.
  - ABVD more likely to cause fetal malformations in first trimester; malformation risk is lower when used in 2nd and 3rd trimesters
  - Vinblastine monotherapy to control symptoms
Incidence
Approximately 8,500 new cases in the United States annually

Prevalence
Approximately 210,000 living with Hodgkin lymphoma in the United States as of 2016

ETIOLOGY AND PATHOPHYSIOLOGY
- RS cells likely derived from germinal center B cells with mutations in immunoglobulin variable chain
- Seasonal features and higher frequencies with Epstein-Barr virus (EBV) suggest environmental factors.
- T-lymphocyte defects persist even after successful treatment.
- Human leukocyte antigen (HLA) is strongly associated with increased risk.
- EBV positivity associated with increased risk
- Genome-wide association studies identified 19p13.3 at intron 2 of TCF3.

Genetics
- First-degree relative: 3 to 9 times risk
- Siblings of younger patients: 7 times risk
- Weak correlation between familial HL and HLA class I regions containing HLA-A1, HLA-B5, HLA-B8, HLA-B18 alleles

RISK FACTORS
- Immunodeficiency (inherited or acquired)
- Autoimmune disorders
- EBV
- Seasonal factors

COMMONLY ASSOCIATED CONDITIONS
In HIV:
- AIDS-defining illness
- Predominantly mixed-cellularity or lymphocyte-depleted histologic subtypes
- At diagnosis: widespread disease, extranodal involvement, systemic symptoms

DIAGNOSIS

HISTORY
- Asymptomatic lymphadenopathy (cervical supraclavicular)
- Pel-Ebstein (cyclic) fever
- Constitutional symptoms: night sweats, weight loss, fatigue, anorexia
- Alcohol-induced pain
- Pruritus

PHYSICAL EXAM
- Lymphadenopathy 70% (cervical > supraclavicular > axillary)
- Splenomegaly
- Hepatomegaly
DIFFERENTIAL DIAGNOSIS
Non-Hodgkin lymphoma, infectious lymphadenopathy, solid tumor metastases, sarcoidosis, autoimmune disease, AIDS/HIV, drug reaction

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Complete blood count (CBC) with differential
- Comprehensive metabolic panel
- Liver function test, lactate dehydrogenase
- End-stage renal disease (ESR)
- HIV, EBV, hepatitis C virus
- Pregnancy test for women of childbearing age
- Echocardiogram (in anticipation of treatment with anthracycline)
- Pulmonary function tests (diffusion capacity of the lung for CO in anticipation of treatment with bleomycin)
- Chest x-ray
- Computed tomography (CT) with contrast of chest, abdomen, and pelvis
- Positron emission tomography (PET): for initial staging, midtreatment decision making, and end-of-treatment evaluation

Follow-Up Tests & Special Considerations
- Fertility considerations:
  - Semen cryopreservation if chemotherapy or pelvic radiation therapy (RT)
  - In vitro fertilization or ovarian tissue/oocyte cryopreservation
- RT considerations:
  - Splenic RT: pneumococcal, Haemophilus influenzae, meningococcal vaccine

Diagnostic Procedures/Other
- Excisional lymph node biopsy
- Immunohistochemistry
- Bone marrow biopsy if cytopenia with negative PET

Test Interpretation
RS cell characteristics include the following:
- Diameter: 20 to 50 μm
- Abundant acidophilic cytoplasm
- Bi- or polylobulated nucleus
- Acidophilic nucleoli
- CD30+, CD15+, CD45−, CD3−, CD20+ in 40% of cases
- RS cells necessary but not sufficient for diagnosis (needs inflammatory background)

TREATMENT
- Ann Arbor staging with Cotswold modification
  - Stage I: single lymph node or of a single extralymphatic organ or site
  - Stage II: ≥2 lymph node regions on the same side of diaphragm alone or with involvement of extralymphatic organ or tissue
Stage III: node groups on both sides of the diaphragm
Stage IV: dissemination involving extranodal organs (except the spleen, which is considered lymphoid tissue)
Subclasses: A = no systemic symptoms; B = systemic symptoms (fever, night sweats, weight loss >10% body weight); X = bulky disease (>1/3 intrathoracic, diameter, or >10-cm nodal mass)
Classified into three groups: early stage (I or II) favorable, early stage unfavorable (I or II with presence of either B symptoms, large mediastinal adenopathy, three or more nodal sites of disease, extranodal involvement, or an ESR ≥50), or advanced stage (III or IV)

- Goal: Aim for cure.
- All subsequent treatment and follow-up care recommendations based on National Comprehensive Cancer Network (NCCN) consensus. Please refer to NCCN Practice Guidelines in Oncology for Hodgkin lymphoma.

MEDICATION
Hodgkin lymphoma

First Line
- Early stage disease: combined modality treatment or chemotherapy
- Advanced stage disease: chemotherapy
- PET/CT used after cycle 2 (PET-2) to guide either escalation or de-escalation of therapy (1)
- ABVD (doxorubicin, bleomycin, vinblastine, dacarbazine):
  - Highly emetic, severe phlebitis
  - Doxorubicin: risk of cardiotoxicity; monitor left ventricular ejection fraction.
  - Bleomycin: risk of pulmonary toxicity, death; test dose may be administered prior to first cycle.
  - Dacarbazine cannot be omitted without loss of efficacy.
- Stage I/II favorable: ABVD × 2 then 20 Gy involved site radiation therapy (ISRT); can also use Stanford V × 8 weeks +/− 30 Gy ISRT pending PET/CT response
- Stage I/II unfavorable: ABVD × 2 then PET-2. If PET-2 negative, then ABVD × 2 + ISRT or AVD [dropped bleomycin (2)] × 4. If PET-2 positive, then ABVD × 2 + ISRT or escalated BEACOPP + ISRT; can also use Stanford V × 12 weeks + 30 to 36 Gy
- Stage III/IV: ABVD × 2 is preferred then AVD [dropped bleomycin (2)] × 4 if PET-2 negative. If PET-2 positive, then ABVD × 2 + ISRT or escalated BEACOPP × 4 +/− ISRT; can also use Stanford V × 12 + ISRT unless refractory or BEACOPP × 6 +/− ISRT pending PET/CT response; also can consider brentuximab vedotin (anti-CD30 chimeric antibody conjugated to synthetic antimicrotubule agent monomethyl auristatin E) Food and Drug Administration (FDA)-approved for use in combination with AVD based on results of ECHELON-1 phase 3 trial, which showed reduced “modified” progression-free survival (PFS) compared to ABVD (HR 0.77; 95% CI, 0.60–0.98; p = .04)

Second Line
- Reserved for patients with relapsed/refractory (R/R) disease
- Standard is for chemotherapy agents not used for initial treatment and then high-dose therapy with autologous stem cell transplant (HDT/ASCT) +/− ISRT.
  - HDT/ASCT shows improved EFS/PFS compared with conventional chemotherapy but not overall survival; can achieve disease-free survival in 30–40% of patients after autologous
stem cell transplant (ASCT)
- Allogeneic SCT to be considered if failed autologous SCT (used in trials only)
- Brentuximab vedotin FDA-approved for use as maintenance therapy × 1 year in relapsed HL after HDT/ASCT or failed two prior lines of multiagent chemotherapy. Strongly encouraged if Deauville of 4 on restaging PET after HDT/ASCT or in patients at high risk for relapse. Improves PFS in those at risk for relapse or progression after transplantation (3). Initial phase II study data showed 73% response rate and 34% CR. 3-year follow-up confirmed responses with OS and PFS rates of 75% and 58%, respectively (4).
- Side effects include peripheral neuropathy, nausea, fatigue, neutropenia, diarrhea.
- May also be used prior to HDT/ASCT to avoid toxicity with HDT
- Pembrolizumab (anti-PD1) FDA-approved for patients with R/R CHL who have failed three lines of therapy. Phase 2 study (KEYNOTE-087) showed ORR and CR rate of 68% and 29%, respectively.
- Nivolumab (another anti-PD1) in a phase 2 study of R/R CHL showed ORR 69% with durable response and favorable safety profile (5).
- Third-line novel agents undergoing studies: NF-κB inhibitors (bortezomib), mammalian target of rapamycin (mTOR) inhibitors (everolimus), immunomodulators (lenalidomide), cell signaling targets histone deacetylase (HDAC) inhibitors (vorinostat, panobinostat, mocetinostat)
- Median survival <3 years if fail second-line therapy, including HDT/ASCT
- NLPHL
  - Treated with rituximab + CHOP (CD20 positive)

**ISSUES FOR REFERRAL**
Initial referral should be made once an excisional lymph node biopsy is performed and a diagnosis is determined.

**SURGERY/OTHER PROCEDURES**
An excisional lymph node biopsy is recommended for initial diagnosis.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Consider placement of a central venous catheter for chemotherapy administration.

**ONGOING CARE**
Patients treated with ABVD become neutropenic. Treatment is continued despite neutropenia with no clear increased risk of infection with or without growth factors.

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- During therapy: CBC, nutrition, and hydration
- Restage with PET after 2 cycles of chemotherapy: sensitive prognostic indicator
- Posttreatment monitoring:
  - History and physical: q3–6mo for first 2 years, then q6–12mo for next 3 to 5 years, and then annually
  - Laboratory studies
    - CBC, platelets, basic metabolic panel, ESR (if elevated at time of diagnosis), as indicated
clinically
  o Thyroid-stimulating hormone (TSH) annually if radiation to neck
  – Imaging:
    o CT is appropriate 6, 12, and 24 months posttreatment as well as when clinically indicated.
    o Annual breast mammogram beginning 8 to 10 years after therapy or at age 40 years
      (whichever first) if chest or axillary irradiation (annual breast MRI as well if initially
      radiated between ages 10 and 30 years) according to the American Cancer Society
    o Surveillance PET should not be done routinely due to risk of false-positive findings.
  • Annual influenza vaccine

PATIENT EDUCATION
• Reproductive impact
• Risks of secondary malignancy
• Oral and dental care during therapy
• Leukemia & Lymphoma Society (http://www.lls.org/)

PROGNOSIS
• Cure rate for CHL: 85%
• Relapse or progression of disease rate: 5–20%
• Overall survival rates:
  – 1-year survival: 92%
  – 5-year survival: 87% (93% if localized)
  – 10-year survival: 80%
• International prognostic score for advanced disease:
  – Age >45 years
  – Male gender
  – Albumin <4 g/dL
  – Hemoglobin <10.5 g/dL
  – Lymphocytopenia: <600 lymphocyte cells/dL or lymphocytes <8% of WBC
  – WBC ≥15,000 cells/dL
  – Stage IV disease
• Main cause of death
  – Initial 5 years: Hodgkin lymphoma
  – After 5 to 10 years: leukemia, myelodysplastic syndrome
  – After 20 years: second primary malignancy, cardiovascular disease

COMPLICATIONS
• Patients can develop peripheral neuropathy after treatment.
• Anthracycline use and radiation exposure increase the risk of cardiovascular and valvular
disease.
• Radiation exposure increases the risk of breast cancer.

ICD10
- C81.90 Hodgkin lymphoma, unspecified, unspecified site
- C81.91 Hodgkin lymphoma, unsp, lymph nodes of head, face, and neck
- C81.92 Hodgkin lymphoma, unspecified, intrathoracic lymph nodes

CLINICAL PEARLS

- Neoplastic disease of lymphatics
- RS cells of monoclonal lymphoid B-cell origin within inflammatory background of lymphocytes
- Two subtypes: CHL 95% of cases and NLPHEL 5% of cases
- CHL cure rate: 85%; 5-year survival: 87%; relapse or progression of disease rate: 5–20%
- Incorporation of anti-CD30 therapy into frontline therapy and immunotherapy with PD1 blockade currently underway and promising
BASICS

DESCRIPTION
Defined as the condition in which (i) an individual or family lacks a fixed, regular, and adequate nighttime residence; or (ii) an individual or family who has a primary nighttime residence that is (a) a public or private place not meant for human habitation; (b) in a publicly or privately operated shelter designated to provide temporary living arrangements; (c) an institution where they have resided for 90 days or less and who resided in an emergency shelter or place not meant for human habitation immediately before entering that institution (1)

EPIDEMIOLOGY
Prevalence
As of January 2018, there are roughly 553,000 homeless individuals in the United States on any given night: 65% are staying in sheltered locations such as emergency shelters or transitional housing and 35% are staying in unsheltered locations such as on the street, in abandoned buildings, or any place unfit for human habitation (2).

- From 2017 to 2018, homelessness increased for the second year in a row by 0.3%, reflective of a 3% increase in the number of people experiencing homelessness in unsheltered locations (2).
- From 2017 to 2018 the number of homeless families with children decreased by 2% and the number of homeless veterans decreased by 5% (2).
- Roughly 36,000 unaccompanied youth, under age 25, experienced homelessness in 2018 (2).
- There was a 2% increase in individuals with chronic patterns of homelessness in 2018 when compared to 2017, driven by a 16% increase in sheltered populations with a 4% decrease in unsheltered populations. However, the number of individuals experiencing chronic homelessness has declined by 26% between 2007 and 2018 (2).

RISK FACTORS
- Economic factors
  - Poverty
    o 2019 federal poverty definition: $25,750 annual income for four-person household in the lower 48 states and District of Columbia, slightly higher in Alaska and Hawaii (3)
    o In 2017, 12.3% of the U.S. population fell below federal poverty definition
  - Lack of affordable health care: In 2016, 8.8% of people in the United States were uninsured for the entire calendar year. In 2017, the percentage of uninsured did not statistically differ from 2016 (4).
    o Working age adults (ages 19 to 64 years) had a lower rate of health insurance in 2017 when compared to children and older adults. Those aged 26 to 34 were least likely to be insured. The uninsured rate for ages 19 to 25 years decreased by 12% between 2009 and 2016, following Affordable Care Act provision allowing individuals in this age group to stay on parental insurance plans (4).
    o The uninsured rate for people under age 19 and between ages 50 and 59 increased from 2016 to 2017 (4).
Lack of affordable housing. Housing is considered affordable if ≤30% of household income is devoted to housing cost. An estimated 37.8 million U.S. households face cost burdens in housing (>30% of income is spent on housing) and 18.2 million households are “severely housing cost burdened” (≥50% of income is spent on housing).

Additional at-risk populations: intimate partner violence (IPV), victims of violence; youth (particularly those aging out of foster care); veterans; rural; addiction; psychiatric illness; disabled due to chronic medical disease, psychiatric illness, or substance use disorder; reentry after incarceration/prison

- IPV: 12% of overall homeless population, and as many as 1 in 5 families, will have reported experiencing IPV; IPV leads directly to homelessness in many cases.
- Youth: On a single night in 2018, 36,000 unaccompanied youth under age 25 experienced homelessness. 89% were ages 18 to 24. 51% of homeless unaccompanied youth were unsheltered.
- Veterans: the number of homeless veterans decreased by 5% from 2017 to 2018 and by 48% since 2009.
- Transgender individuals: In 2018, 0.5% of all persons experiencing homelessness identified as transgender and 0.2% identified as gender nonconforming.
- Addiction disorders: 46% of homeless individuals report alcohol and/or drug use as a major factor contributing to homelessness.
- Psychiatric illness: 45% of homeless report indicators of a mental health issue in the past year; 25% of homeless adults suffer from chronic mental illness.
- Reentry after incarceration: Up to 50,000 people each year enter homeless shelters from jails or prisons.

Fundamental issues in homelessness and health care that require ongoing consideration:

- Unstable housing, limited access to nutritious food and water, lack of transportation
- Higher risk for abuse and violence
- Physical/cognitive impairments, behavioral health problems
- Developmental discrepancies for children: speech delay, chronic ear infection, insufficient opportunity to practice gross and fine motor skills
- Higher risk for communicable disease
- Lack of health insurance/resources, discontinuous/inaccessible health care, lack of a medical home, barriers to disability assistance
- Cultural/linguistic barriers: racial and ethnic groups overrepresented in homeless population
- Limited education/literacy
- Lack of social supports: Alienation from family and friends precipitate homelessness.
- Criminalization of homelessness: frequent arrests for loitering, sleeping in public places

GENERAL PREVENTION

- Policy and funding for community programs to provide emergency/rapid housing, housing stabilization, and case management services
- Increased Medicaid eligibility for homeless and expanded home and community-based services and case management to the homeless population
- Department of Housing and Urban Development (HUD): increasing permanent supportive housing units, increasing services for veterans and those with disabilities
- Social justice policy recommendations: permanent affordable housing, foreclosure and homelessness prevention, increased funds for HUD, McKinney-Vento programs (emergency, transitional, and permanent housing) and National Housing Trust Fund, rural homeless
assistance, universal health care, universal livable income, employment/workforce services, prevention of hate crimes against the homeless, decriminalization of homelessness

COMMONLY ASSOCIATED CONDITIONS

- Hunger
- Worsening of chronic medical conditions: lack of healthy food, places to store medications, or medical equipment; lack of restful sleep; decreased health literacy; limited transportation to appointments
  - Infectious diseases
    - Tuberculosis (TB), HIV/AIDS, sexually transmitted infection (STI)
    - Skin/nail infections and infestation (lice, bedbugs, and scabies)
    - Liver disease (e.g., hepatitis B or C, or alcohol related)
  - Cognitive impairment: traumatic brain injury (TBI), cerebrovascular accident (CVA), substance use
  - Dental problems
  - Exposure-related conditions (frostbite, heatstroke)
  - Psychiatric illness
  - Trauma: increased risk of assault, victims of hate crimes

DIAGNOSIS

HISTORY

- Living conditions: location, access to food, restrooms, place to store medicines, safety
- Prior homelessness: causes and circumstances
- Individual/family history of reactive airway disease (RAD), chronic otitis media, anemia, diabetes, cardiovascular disease (CVD), TB, HIV/STIs, hospitalizations
- Family members, especially dependent children
- Medications: include over-the-counter medication, dietary supplements, medication “borrowed” from others
- Prior providers: oral health, primary and specialty care, current medical home
- Mental health: stress, anxiety, appetite, sleep, concentration, mood, speech, memory, thought process and content, auditory/visual hallucinations, suicidal/homicidal ideation, insight, judgment, impulse control, social interactions; symptoms of brain injury (headaches, seizures, memory loss, irritability, dizziness, insomnia, poor organizational/decision-making skills), trauma history
- Alcohol/nicotine/drug use: amount, frequency, duration
- Gender identity/orientation, behaviors, rape, pregnancies, hepatitis, HIV, other STIs
- History of or current abuse: emotional, physical, sexual; patient safety
- Legal problems/violence: history of incarceration
- Activities: routines (treatment feasibility); level of strenuous activity
- Work: previous types of jobs, length held, veteran status, occupational injuries/toxic exposures; vocational skills, interest
- Education: highest level; ever in special education; assess ability to read/language skills/English fluency.
- Nutrition/hydration: diet, food resources, preparation skills, liquid intake
- Cultural heritage/affiliations: family, friends, faith community, other sources of support
Strengths: coping skills, job skills, resourcefulness, abilities, interests

PHYSICAL EXAM
- Comprehensive exam: height/weight, body mass index, especially abdominal, cardiopulmonary, dermatologic, oral, feet, neurologic, mental status
- Focused exams: for patients uncomfortable with full-body, unclothed exam at first visit
- Dental assessment: age-appropriate teeth, obvious caries, dental/referred pain, diabetes, CVD

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Mental health: Patient Health Questionnaire (PHQ-9, PHQ-2), MHS-III, MDQ, GAD-7
- Cognitive assessment: Mini-Mental State Examination (MMSE), Traumatic Brain Injury Questionnaire (TBIQ), Repeatable Battery for the Assessment of Neuropsychological Status (RBANS)
- Developmental assessment: Ages & Stages Questionnaires, Parents’ Evaluation of Developmental Status (PEDS), Denver II, or other screening tool
- Interpersonal violence: IPV, sexual assault, TBI
- Forensic evaluation: if indicated by history
- Baseline labs: as needed to address suspected medical concerns
- TB screening: PPD or T-SPOT/QuantiFERON-TB Gold if available
- STI screening: HIV, chlamydia, gonorrhea, syphilis, hepatitis B, hepatitis C, trichomoniasis
- Substance abuse: Simple Screening Instrument for Alcohol and Other Drugs (SSI-AOD), urine drug screen

Follow-Up Tests & Special Considerations
- Reproductive health care and STIs: Obtain detailed sexual history (sexual identity, orientation, behaviors/sexual practices, number of partners). Consider patient exploitation, especially if mental illness/developmental disability suspected. Communicate willingness to initiate contraception first visit without exam. Genital exam recommended, but be sensitive to patient needs, if possible sexual abuse history. If pelvic exam is refused, consider empiric treatment for STI (and possibility of multiple orifice infection). Dispense medications on site; facilitate partner treatment.
- Pediatric care: complete exam every visit; use each visit to identify/address problems and provide vaccinations because homeless families may not see a medical provider unless child is sick. Vision and hearing screening at every visit. Facilitate referrals as able.

TREATMENT
- Establish rapport: Many patients will have had negative health care experiences.
- Enlist community resources: mental health and substance abuse programs, free clinics, case management.
- Health care maintenance: vaccinations (hepatitis A and B, Pneumovax, Tdap, influenza), cancer, and chronic disease screening for adults; Early and Periodic Screening, Diagnosis, and Treatment (EPSDT) program screening and vaccinations for children
- Care plan
  - Basic needs: Food, clothing, and housing may be higher priorities than health care.
  - Patient goals and priorities: immediate/long-term health needs. Address patient concerns
first.
– Action plan: simple language, pocket card
– After hours: extended clinic hours and access
– Safety plan: violence and abuse; mandatory reporting requirements
– Emergency plan: location of nearest emergency department (ED), preparation for evacuation
– Adherence plan: use of interpreter; identification of potential barriers

MEDICATION
• Simple regimen: low pill count, once-daily dosing
• Dispensing: small amounts on site to promote follow-up, decrease loss/theft/misuse. Determine resources for written prescriptions.
• Storage of medications: If no access, avoid medications requiring refrigeration.
• Patient assistance: free/low-cost drugs depending on available local options
• Aids to adherence: harm reduction, outreach/case management, directly observed therapy
• Side effects: Primary reason for medication nonadherence are drugs causing diarrhea, polyuria, nausea, and/or disorientation.
• Analgesia/symptomatic treatment: Consider pain contract, single provider for pain medication refills
• Dietary supplements: multivitamins with minerals, nutritional supplements
• Managed care: generics, if possible; assistance getting prescription filled
• Lab monitoring: Monitor patients on antipsychotic medications for metabolic disorders using available laboratory resources.

ADDITIONAL THERAPIES
• Associated problems/complications
  – Fragmented care: multiple providers. Use electronic medical record (EMR) as possible; list prescribed medication on wallet-sized card.
  – Masked symptoms/misdiagnosis: for example, weight loss, dementia, edema, lactic acidosis
  – Focus on immediate concerns, not possible future consequences.
  – Integrated treatment for concurrent mental illness/substance use disorders
  – Support for parent of child abused by others and for abused parent
  – Large appointment burdens: For those individuals who suffer from multiple chronic illnesses, specialty care may be difficult to obtain due to the many barriers to care listed above.
• Follow-up
  – Reliable phone/e-mail contact for patient/friend/family/case manager
  – Frequent follow-up, incentives, nonjudgmental care regardless of adherence
  – Anticipate/accommodate unscheduled clinic visits.
  – Provide car fare, tokens, and help with transportation services.
  – Monitor school attendance and address health/developmental problems with family/school.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Homeless likely to benefit from admission if living conditions are suboptimal to treat medical, psychiatric, and substance use disorders.
• Discharge criteria
  – Bed rest, extended periods of elevation, rest, or icing are not feasible in most instances.
– Plans requiring multiple return visits likely to fail if no transportation.
– Admission to inpatient rehabilitation if appropriate and possible

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Patients with a history of nonadherence need additional support (e.g., case manager, outreach) to succeed in ongoing care after hospital discharge.
- Limited telephone access to schedule appointments; may be unable to receive telephone messages with test results or rescheduled appointment times. Some social service agencies will provide phone, mail, e-mail, Internet, and laundry services.
- Arrange appointments prior to discharge.
- Document the best way to contact the individual.
- Work with experienced health care agency designed to address physical/mental health services and substance use treatment.

**PATIENT EDUCATION**

- [https://www.nhchc.org/](https://www.nhchc.org/)
- [https://www.endhomelessness.org/pages/mentalphysical_health](https://www.endhomelessness.org/pages/mentalphysical_health)

**PROGNOSIS**

Mortality rates for homeless adults are 3 to 4 times higher compared with general U.S. population (6)[C].

**REFERENCES**

CODES

ICD10
- Z59.0 Homelessness
- Z59.1 Inadequate housing
- Z59.8 Other problems related to housing and economic circumstances

CLINICAL PEARLS

- Permanent supportive housing is an important step toward ending homelessness, in accordance with a Housing First approach.
- Assistance in gaining access to benefits or providing help to support basic needs decreases stress, improves therapeutic relationship, and allows individuals to focus on physical and mental health.
HORDEOLUM (STYE)
Konstantinos E. Deligiannidis, MD, MPH, FAAFP

BASICS

DESCRIPTION
- An acute inflammation or infection of the eyelid margin involving the sebaceous gland of an eyelash (external hordeolum) or a meibomian gland (internal hordeolum)
- System(s) affected: skin/exocrine
- Synonym(s): internal hordeolum; external hordeolum; zeisian sty; meibomian sty; stye

EPIDEMIOLOGY
- Predominant age: none
- Predominant sex: male = female

Incidence
Unknown: Although external hordeolum is common, internal hordeolum is rare.

ETIOLOGY AND PATHOPHYSIOLOGY
- Bacterial infection of sweat or sebaceous glands, causing an acute inflammatory reaction
- In an internal hordeolum, the meibomian gland may become obstructed, leading to a pustule on the conjunctival surface as opposed to the margin of the eyelid.
- Most commonly caused by Staphylococcus aureus (~90–95% of all cases) or by Staphylococcus epidermidis
- Seborrhea can predispose to infections of the eyelid.

Genetics
No known genetic pattern

RISK FACTORS
- Poor eyelid hygiene
- Previous hordeolum
- Contact lens wearers
- Application of makeup
- Seborrheic dermatitis
- Predisposing blepharitis (low-grade infections of the eyelid margin)
- Ocular rosacea

GENERAL PREVENTION
Eyelid hygiene

COMMONLY ASSOCIATED CONDITIONS
- Acne
- Seborrhea
- An association may exist between hordeolum during childhood and developing rosacea in adulthood.
DIAGNOSIS

HISTORY
- Localized inflammation (vs. involvement of the entire eyelid or surrounding skin)
- Foreign body sensation in the eye
- Prior episodes are common.

PHYSICAL EXAM
- Localized inflammation of the eyelashes or a small pustule at the margin of the eyelid
- Localized swelling and tenderness on the internal or external aspect of the eyelid with an opening to either side
- To determine if an internal hordeolum is obstructed, the eyelid should be gently everted to examine for a pustule on the tarsal conjunctiva.
- Itching or scaling of the eyelids; collection of discharge, redness, and irritation leading to localized tenderness and pain
- The size of the swelling usually correlates to the severity of the hordeolum.

DIFFERENTIAL DIAGNOSIS
- Chalazion
- Blepharitis
- Eyelid neoplasms
- Periorbital cellulitis
- Dacryocystitis
- Squamous cell carcinoma

DIAGNOSTIC TESTS & INTERPRETATION
Culture of the eyelid margins usually is not necessary.

Diagnostic Procedures/Other
History and eye exam

Test Interpretation
Bacterial contamination and white cells in eyelid discharge

TREATMENT

GENERAL MEASURES
- The hordeolum should not be expressed.
- Warm compresses to the area of inflammation can help increase blood supply and encourage spontaneous drainage.
- Good personal hygiene with attention to cleansing the eyelids on a daily basis helps to prevent recurrent infections.

MEDICATION

First Line
- A Cochrane review found no evidence for or against nonsurgical treatment of internal hordeolum. External hordeola were not considered (1)[A].
Usually, a hordeolum spontaneously drains, aided by warm compresses to the area. Also, lid scrubs, digital massage, and alternative medicine have been used to reduce healing time and relieving symptoms.

Application of an antibiotic ointment (e.g., erythromycin) to the margin of the eyelid after proper cleansing (except in children age <12 years, in whom there is a risk of blurred vision and ambly-opia) helps reduce bacterial proliferation. There is little evidence that any topical therapy is effective. Erythromycin ophthalmic ointment may be applied up to 6 times per day for 7 to 10 days or an antibiotic ointment containing bacitracin (2,3)[C].

Treat underlying dry eye with artificial tears.

Second Line

Occasionally, the use of an aminoglycoside ophthalmic ointment, such as gentamicin or tobramycin, may be necessary if condition is refractory to simpler treatment (case reports).

Oral dicloxacillin or cephalixin for 2 weeks if refractory to topical antibiotics

ISSUES FOR REFERRAL
Consider referral if unresponsive to oral antibiotics.

SURGERY/OTHER PROCEDURES

If the infection becomes localized to a single gland, incision, drainage, or curettage sometimes is necessary. This is an in-office procedure with a local anesthetic: Exercise caution because ocular perforation has been reported with the injection of an anesthetic to an infected lid.

Use of combined antibiotic ointment (neomycin sulfate, polymyxin B sulfate, and gramicidin) after surgery was not shown to have any statistically significant benefit compared with artificial tears.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Broncasma berne is a polyvalent antigen vaccine that may be useful in the treatment of recurrent hordeolum.

A Cochrane review found low-quality evidence that acupuncture (with or without antibiotics and/or warm compresses) may increase the chance of improvement of hordeolum compared to antibiotics and/or warm compresses (4)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Outpatient

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

No restrictions

Patient Monitoring
The patient should be seen within several weeks to assess the effectiveness of therapy or should at least call the physician’s office with a progress report.

DIET
No special diet
PATIENT EDUCATION
- The patient should be instructed in proper cleansing of the eyelids using a solution of tap water and baby shampoo or a commercially prepared hypoallergenic cleanser.
- The sty should not be squeezed or incised.

PROGNOSIS
- Usually responds well to good hygiene and warm compresses
- Inflammation usually improves within a week.
- Hordeolum tends to recur in some patients, usually due to incomplete elimination of bacteria.

COMPLICATIONS
An internal hordeolum, if untreated, may lead to chalazion, infections of adjacent glands, or generalized cellulitis of the lid.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- H00.019 Hordeolum externum unspecified eye, unspecified eyelid
- H00.029 Hordeolum internum unspecified eye, unspecified eyelid
- H00.039 Abscess of eyelid unspecified eye, unspecified eyelid
CLINICAL PEARLS

- A hordeolum should not be expressed.
- Warm compresses to the area of inflammation can encourage spontaneous drainage.
- Application of an antibiotic ointment (e.g., erythromycin) to the margin of the eyelid after proper cleansing helps reduce bacterial proliferation but may have no effect on the healing of the stye.
- Good personal hygiene with attention to cleansing the eyelids on a daily basis can prevent recurrent infections.
HORNER SYNDROME
Iain W. Decker, DO  ●  Zaiba Malik, MD

BASICS

DESCRIPTION
- Horner syndrome is a constellation of neurological signs and symptoms manifested as a classic triad of ipsilateral miosis, eyelid ptosis, and anhidrosis of the ipsilateral face and/or neck (with iris heterochromia in children).
- It is caused by the interruption of sympathetic nervous system innervation to the head, neck, and eye.
- System(s) affected: nervous, skin/exocrine
- Synonym(s): Bernard-Horner syndrome; Bernard syndrome; Horner syndrome; cervical sympathetic syndrome; oculosympathetic syndrome; oculosympathetic paralysis; oculosympathetic deficiency; oculosympathetic paresis

EPIDEMIOLOGY
- Predominant age: none
- Predominant sex: male = female

Incidence
- Estimated incidence of pediatric Horner syndrome is 1.42 per 100,000 in patients younger than 19 years of age, with a birth prevalence of 1 in 6,250 for those with congenital onset of Horner syndrome.
- Incidence in adults is not known.

Prevalence
Unknown

ETIOLOGY AND PATHOPHYSIOLOGY
- Oculosympathetic pathway anatomy:
  - First-order neuron: Sympathetic nerve fibers originate in the hypothalamus, descend through the brainstem, and synapse at the ciliospinal center (of Budge-Waller) located at approximately the C8–T2 levels of the spinal cord.
  - Second-order neuron: exits the spinal column, arches over the apex of the lung and under the subclavian artery, ascending to the superior cervical ganglion at the level of the carotid bifurcation and angle of the jaw (C2)
  - Third-order neuron: ascends along the adventitia of the internal carotid artery, through the cavernous sinus in proximity to cranial nerve (CN) VI and the trigeminal ganglion, and joins the nasociliary branch of CN V1 to enter the orbit—innervating the iris dilator muscle, Müller muscle in the upper eyelid, and inferior retractors in the lower eyelid.
- A lesion affecting the neurons in the sympathetic chain (first, second, or third order) may produce signs and symptoms of Horner syndrome as a result of a lack of sympathetic input to the orbit.
  - Ptosis: Sympathetic innervation to the Müller muscle in the upper eyelid and the lower eyelid retractors helps to maintain normal eyelid position. When sympathetic innervation to
these structures is interrupted, a subtle ptosis of both the upper lid (ptosis) and lower lid (reverse ptosis) may result. This ptosis may be subtle, often 2 mm or less.

- Meiosis: The radially oriented pupillary dilator muscle produces pupillary dilation in response to stimulation by the sympathetic nervous system. Anisocoria will be more pronounced in dim lighting, reflecting impairment of dilation in the affected eye. The affected eye will constrict normally in response to light but will be slower to dilate than the unaffected pupil.

- Anhidrosis: When present, anhidrosis may assist in localizing a lesion. Sympathetic fibers innervating sweat glands of the lower face and vasodilatory muscles branch off before the superior cervical sympathetic ganglion and travel along the external carotid artery. Lesions affecting primary and secondary neurons are more likely to produce anhidrosis of both the upper and lower face.

Etiologies of Horner syndrome are best classified by which neuron in the sympathetic chain is affected (first/second/third order) and by age (pediatric vs. adult).

Etiologies in adults:
- First-order neuron lesions located in hypothalamus/brainstem (lateral medulla)/spinal cord (cervico-thoracic) include:
  - Arnold-Chiari malformation, basal meningitis (e.g., syphilis), cerebral vascular accident: lateral medullary (Wallenberg) syndrome, cervical cord trauma, cervical spondylosis, demyelinating disease (multiple sclerosis), Intrapontine hemorrhage, neck trauma, syringomyelia/syringobulbia, tumor (basal skull, pituitary), unintended subdural placement of lumbar epidural catheter.
- Second-order neuron pulmonary or cervico-thoracic lesions include:
  - Aneurysm/dissection of aorta, central venous catheterization, chest tubes, 1st rib fracture, lymphadenopathy (Hodgkin, leukemia, tuberculosis, sarcoid), mandibular tooth abscess, neuroblastoma, Pancoast tumor or infection of lung apex, proximal common carotid artery dissection, thoracic outlet obstruction (cervical rib, subclavian artery aneurysm), trauma/surgical injury, tumor (thyroid, mediastinum).
- Third-order neuron lesions located in superior cervical ganglion, internal carotid artery, skull base, cavernous sinus, or orbit include:
  - Carotid cavernous fistula or other pathology, carotid endarterectomy or carotid artery stenting, cluster headaches/paroxysmal hemicrania, internal carotid artery dissection, herpes zoster, lesions of the middle ear (acute otitis media), Lyme disease, tumor (nasopharyngeal, pituitary, paratrigeminal, metastasis, skull base), tonsillectomy, trauma/surgical injury, raeder paratrigeminal syndrome.

Etiologies in children:
- Birth trauma/neck trauma (injury to the brachial plexus)—most common. Brainstem glioma, neuroblastoma, vascular anomalies, surgical interventions in the neck/chest, Idiopathic.

**Genetics**
Rare autosomal dominant inheritance

**RISK FACTORS**
- Recent trauma to the head/neck/thorax (e.g., motor vehicle accidents)
- Smoking (Pancoast tumor)
- Known aneurysm of the carotid or subclavian arteries
- Known malignancy/tumor/mass.
• Previous surgery (Neck/thoracic)
• Previous instrumentation of the head/neck/thoracic regions (chest tube, central venous catheterization)
• Cluster headache

DIAGNOSIS

HISTORY
• When did symptoms begin? (acute vs. chronic)
• Any visual symptoms? (blurred vision, field loss, transient visual loss, diplopia)
• Previous ophthalmic history? (eye trauma, surgery)
• Are symptoms associated with pain? (ipsilateral head/neck/face)
• Recent head/neck trauma?
• Recent surgical procedures?
• Any associated headaches?
• Any other neurologic signs?
• Does the degree of ptosis vary over the course of the day or with fatigue?
• Any sweating abnormalities or flushing on one side of the face?

Pediatric Considerations
In infants and children, loss of facial flushing is appreciated more than anhidrosis (harlequin sign—affected side will appear pale secondary to denervation supersensitivity to circulating adrenaline). New onset, non-traumatic Horner syndrome in a child necessitates workup for neuroblastoma.

ALERT
Horner syndrome in the presence of pain merits urgent evaluation and referral to the emergency room.

• Acute-onset, ipsilateral facial or neck pain: Consider carotid artery dissection until proven otherwise, even in the absence of obvious head/neck trauma.
  – Pain from dissection is usually located around the temple and orbit. Patients may also experience amaurosis fugax and dysgeusia. If missed, stroke is a potential complication.
• Axial, shoulder, scapula, arm, or hand pain may be related to Pancoast tumor or cervical cord lesion.
• Paratrigeminal syndromes:
  – Raeder paratrigeminal syndrome type I: orbital pain, miosis, ptosis, with associated ipsilateral lesions of CN III to VI; suspect middle cranial fossa mass or cavernous sinus lesion.
  – Raeder paratrigeminal syndrome type II: episodic retrobulbar or orbital pain, miosis, ptosis with no CN lesions; suspect migraine variant.

PHYSICAL EXAM
• Evaluate pupillary function:
  – Measure pupillary diameter under both dim and bright lighting to determine presence of anisocoria. In Horner syndrome, anisocoria will be greater in dim/dark lighting conditions.
  – Evaluate pupil reactivity to light and accommodative response.
– A pupillary dilation lag may be present, and the affected pupil may gradually dilate 5–15 seconds after exposure to light.

- Evaluate for lid ptosis:
  – Examine the upper lids for ptosis (often <2 mm).
  – A “reverse ptosis” of the lower lid may also be visible in the form of a slight elevation of the lower lid relative to the unaffected eye.

- Evaluate for anhidrosis:
  – This may be difficult. Subtle signs of anhidrosis include flushing of the skin on the involved side.

- Additional acute features of sympathetic disruption may include ipsilateral conjunctival injection and nasal congestion.

- Biomicroscopic/slit lamp exam of the eye, including iris structure and color (if available)
  – In congenital Horner syndrome, the affected iris shows reduced pigmentation, blue-gray, and mottling of the affected eye (heterochromia iridis) because formation of iris pigment early in life is under sympathetic control.

- Observe for the presence of nystagmus, facial swelling, lymphadenopathy, or vesicular eruptions.

- A full cranial nerve exam with special attention to extraocular movements

- Palpation and inspection of the neck for any masses or evidence of trauma

- Neurologic and chest exams for associated physical findings

DIFFERENTIAL DIAGNOSIS

- Physiologic anisocoria (~20% population)
  – Physiologic variation often varies by less than 1mm and may fluctuate throughout the day.

- Neurologic diseases versus neuromuscular junctional disease (myasthenia gravis, botulinum toxin)

- 3rd nerve palsy

- Aponeurotic ptosis

- Congenital ptosis

- Adie tonic pupil

- Intermittent unilateral pupillary mydriasis (sympathetic vs. parasympathetic form)

- Damage to the iris sphincter muscle

- Pharmacologic causes including unilateral use of miotics or mydriatics, acetophenazine, alseroxylon, bupivacaine, butaperazine, carphenazine, chloroprocaine, deserpidine, diacetylmorphine, diethazine, ethopropazine, etidocaine, guanethidine, influenza virus vaccine, levodopa, lidocaine, mepivacaine, mesoridazine, methdilazine, methotrimetrazine, oral contraceptives, perazine, prilocaine, procaine, prochlorperazine, promazine, propoxycaine, reserpine, thioproperazine, thioridazine, trifluoperazine

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Lab: CBC, FTA-ABS, VDRL, purified protein derivative; vanillylmandelic acid (VMA), homovanillic acid I (HVA) to rule out neuroblastoma in pediatric patients

- Imaging considerations are unique because of the long pathway traveled by the sympathetic nervous system. A lesion at any point along this pathway, extending from the hypothalamus down to T2, may contribute to the onset of Horner syndrome.

- Clinicians should attempt to follow 3 steps in the evaluation of a patient with Horner
syndrome:
– Clinical diagnosis of Horner Syndrome
– Pharmacologic confirmation of Horner Syndrome
– In the chronic setting, a single neuroimaging study of the oculosympathetic pathway extending from the hypothalamus down to T2 with a contrast-enhanced MRI, with or without MRA of the head and neck
– In the acute setting (or for patients unable to tolerate MRI), an initial CT scan of the head/neck and computed tomography angiography (CTA) of the neck followed by HS MRI if initial CT/CTA are negative. Life-threatening causes of Horner syndrome including carotid artery dissection may be ruled out with this initial CT/CTA to avoid delay in treatment (1)[B].

**Pediatric Considerations**
In a child of any age without contributory history, MRI brain, neck, and chest as outlined above is appropriate. Clinicians may consider MRI abdomen as well if clinical suspicion of neuroblastoma is high.

**Pregnancy Considerations**
In the pregnant population, the safety of MRI for the fetus has not yet been established. Most authors believe that pregnant patients may undergo MRI safely, but it should be noted that contrast material (e.g., gadolinium) is FDA category C (1)[B].

**Diagnostic Procedures/Other**
- To diagnose Horner syndrome, a confirmation test is required. The first two of these tests (apraclonidine and cocaine) help to confirm the presence of Horner syndrome, whereas the third (hydroxyamphetamine) attempts to localize the lesion. It is usually not necessary to test with both apraclonidine and cocaine, and most choose apraclonidine due to the challenge associated with obtaining cocaine drops.
  - **Topical 0.5% apraclonidine drops:** (2)[A],(3,4)[B]
    - Apraclonidine is a strong alpha-2 agonist and weak alpha-1 agonist with little to no effect on the normal pupil. Instillation tests for denervation supersensitivity of the dilator muscle of the pupil. This develops after an interruption in sympathetic input. This weak alpha-1 agonist activity is enough to dilate the supersensitive Horner pupil. To test for Horner syndrome, 1 drop of apraclonidine is placed in each eye, and the patient is re-assessed after 60 minutes.
    - A positive test result occurs when both pupils become equally sized, or if the affected pupil becomes the larger one. Note: The apraclonidine test may be negative in cases of acute trauma, as there has not been enough time for denervation hypersensitivity to develop (2–5 days).
    - Caution: Do not use in infants <6 months, as alpha-2 activity can cause respiratory depression. May consider cocaine testing in this age group
  - **4–10% topical cocaine drops:**
    - Cocaine blocks reuptake of norepinephrine from the synaptic cleft. To test for Horner syndrome, two drops of 4% or 10% cocaine are instilled in both eyes 5 minutes apart and after 40–60 minutes the pupils are re-evaluated.
    - Cocaine drops will dilate the normal pupil. The miotic pupil in Horner syndrome (regardless of location of lesion) will not dilate or will dilate poorly after 45 minutes
because of the absence of norepinephrine at the nerve endings of the third-order neuron (2)[A]. Positive test is anisocoria of ≥1 mm.

- Topical 1% hydroxyamphetamine drops (2)[A]
  - Used to differentiate between preganglionic (first and second order neurons) and postganglionic (third order neuron) Horner syndrome. Hydroxyamphetamine causes release of endogenous norepinephrine stored in the postganglionic neuron, causing pupillary dilation.
  - One hour after instillation of 1% hydroxyamphetamine drops, the pupils should be evaluated. Dilation of both pupils indicates a lesion of the first or second order neurons. Failure of the pupil to dilate, or poor dilation, indicates a third-order neuron lesion (test considered positive when anisocoria increases by ≥1 mm).
  - No pharmacologic test exists to differentiate between a first- and second-order neuron lesion.

- Must wait 24 to 72 hours between the cocaine and hydroxyamphetamine tests as cocaine may inhibit uptake of hydroxyamphetamine and alter the accuracy of the test.

**Pediatric Considerations**

Due to transsynaptic degeneration in children, the hydroxyamphetamine test is not reliable.

---

**TREATMENT**

**GENERAL MEASURES**

- Treatment generally revolves around addressing any underlying etiologies.
- Once life-threatening etiologies have been excluded, cosmesis or functional vision impairment due to ptosis may be addressed if symptoms have persisted for 12 months.

**MEDICATION**

Carotid artery dissection: Pharmacologic treatment options include thrombolysis, antithrombotic therapy with anticoagulation, or antiplatelet therapy. No randomized control trials have compared these treatment options (5)[C].

**ISSUES FOR REFERRAL**

Depending on etiology of Horner syndrome, referrals may include neurosurgery, oncology, interventional radiology, pulmonology, neurology/neuro-ophthalmology, and oculoplastic surgery.

**SURGERY/OTHER PROCEDURES**

- Surgical intervention depending on etiology
- Consider ptosis repair for cosmesis or functional vision impairment secondary to ptosis if symptoms have persisted for 12 months (oculoplastics).

---

**ONGOING CARE**

**PROGNOSIS**

- Postganglionic: usually benign
- Central and preganglionic: poorer prognosis
COMPLICATIONS

- Chronic pupillary constriction
- Cosmesis

REFERENCES

ADDITIONAL READING

CODES

ICD10

- G90.2 Horner’s syndrome
- S14.5XXA Injury of cervical sympathetic nerves, initial encounter

CLINICAL PEARLS

- Horner syndrome triad: ipsilateral miosis, eyelid ptosis, and anhidrosis caused by a lesion of the oculosympathetic pathway
- Red flag: Horner syndrome in the presence of acute-onset, ipsilateral facial or neck pain: Consider carotid artery dissection until proven otherwise.
- Ptosis is mild, usually <2 mm.
HYDROCELE
Jared M. Patton, MD, MS • John E. Laird, MD, FAAFP, FAAMA

BASICS

DESCRIPTION
A collection of fluid between the parietal and visceral layers of the tunica vaginalis within the scrotum
- Communicating hydrocele (patent processus vaginalis)
  - Direct communication with the peritoneal cavity
  - Contains peritoneal fluid
  - Almost always with associated indirect inguinal hernia
  - Decreases in size with recumbent position
- Noncommunicating hydrocele (The processus vaginalis is not patent.)
  - No direct connection to the peritoneal cavity
  - Fluid contained is from the mesothelial lining.
  - Can be isolated to the cord with the distal and proximal portions of the processus vaginalis closed
- Acute hydrocele: fluid collection resulting from an acute process within the tunica vaginalis, typically involving only the scrotum
- System(s) affected: urogenital

Pediatric Considerations
In a communicating hydrocele, consider contralateral inguinal exploration to rule out an occult indirect hernia.

EPIDEMIOLOGY
Predominant age: childhood

Incidence
Estimated at 0.7–4.7% of male infants

Prevalence
- 1,000/100,000
- Estimated at 1% of adult men

ETIOLOGY AND PATHOPHYSIOLOGY
- Incomplete closure of the processus vaginalis trapping peritoneal fluid anywhere along the length of the tunica vaginalis
- Failure of closure of the processus vaginalis maintaining a communication to the peritoneal cavity
- Imbalance of the secretion and reabsorption of fluid from the lining of the tunica vaginalis
- Infection
- Tumors
- Trauma
- Ipsilateral renal transplantation
RISK FACTORS
- Ventriculoperitoneal shunt
- Exstrophy of the bladder
- Cloacal exstrophy
- Ehlers-Danlos syndrome
- Peritoneal dialysis

COMMONLY ASSOCIATED CONDITIONS
- Testicular tumors
- Scrotal trauma
- Ventriculoperitoneal shunt
- Nephrotic syndrome
- Renal failure with peritoneal dialysis

DIAGNOSIS

HISTORY
- Acute, subacute, or chronic swelling of the scrotum or inguinal canal
- Frequent changes in size of the hydrocele with position change or activity (indicative of communicating)
- Usually painless unless acute onset
- Sensation of heaviness or pressure in the scrotum
- Pain radiating to the flank/back

PHYSICAL EXAM
- Swelling in the scrotum or inguinal canal
- Scrotal mass, usually fluctuant
- Fluctuation in size with change of position (communicating hydrocele)
- Scrotal mass that transilluminates

DIFFERENTIAL DIAGNOSIS
- Indirect inguinal hernia
- Orchitis
- Epididymitis
- Varicocele
- Traumatic testicular injury
- Testicular torsion or torsion of appendix testes
- Testicular neoplasm

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Inguinoscrotal ultrasound (US): can demonstrate the presence of bowel (e.g., distinguish incarcerated hernia from a hydrocele of the cord) as well as the presence of testicular torsion
- Testicular MRI when US is unable to distinguish etiology
- Doppler US or testicular nuclear scan can distinguish testicular torsion.
Aspiration of a hydrocele for diagnosis is not indicated and may lead to severe complications if herniated bowel is present.

**Test Interpretation**
Patent processus vaginalis on imaging in communicating hydroceles

### TREATMENT

#### ISSUES FOR REFERRAL
- Urology referral for symptomatic adults or if underlying diagnosis is unclear
- Pediatric urology/surgery referral for children with symptomatic noncommunicating hydrocele
- Children with communicating hydroceles can be expectantly managed until at least 2 years of age to allow time for spontaneous resolution, unless there is a concern for inguinal hernia (1) [C].
- New onset hydrocele in late childhood and pre-adolescent patients typically resembles the adult type hydrocele pathology (2) [B].

#### SURGERY/OTHER PROCEDURES
- Children: Surgical treatment is generally deferred until 2 years of age because many hydroceles will spontaneously resolve. Some evidence shows that delaying longer than 2 years may be appropriate and decreases unnecessary surgery (1) [C].
  - When surgery is indicated, children with communicating hydroceles may undergo either open or laparoscopic approach.
    - Open inguinal approach involves ligation of the processus vaginalis and excision, distal splitting, or drainage of hydrocele sac (in a hydrocele of cord, the sac can be completely removed).
    - Open scrotal approach involves ligation and removal of the processus vaginalis. The benefit of this approach is improved cosmesis and decreased operative time (3) [B].
    - Laparoscopic repair offers the benefit of contralateral exploration.
- Adults: No therapy is needed unless the hydrocele causes discomfort or unless there is a significant underlying cause such as a tumor.
  - Aspiration of the hydrocele with instillation of a sclerosing agent has been successfully used in adults (4) [A].
  - If resection is indicated, a scrotal approach with resection of hydrocele sac has the lowest recurrence rate.
    - Postoperative complications as well as cost and time to work resumption were less in treatment by aspiration and sclerotherapy versus resection, but the recurrence rate was higher (5) [A].
    - The recurrence rate and low patient satisfaction may relegate aspiration, and sclerotherapy as an alternative option only when resources for surgery are limited (6) [A].

#### ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Open inguinal or scrotal approach is typically performed as an outpatient.
- Laparoscopic approach in pediatric patients may require 24-hour admission for postoperative monitoring.
- Sclerotherapy is a same-day office procedure.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Depending on method of treatment, initial follow-up is generally in the first 4 to 6 weeks.
- With sclerotherapy, follow-up is for confirmation of resolution or to proceed with retreatment.
- Postoperative follow-up at 2 to 4 weeks and subsequent 2- to 3-month intervals until resolution of any postoperative complications

PROGNOSIS

Low risk of long-term sequelae with either treatment method

COMPLICATIONS

- Complication rate for a scrotal approach may reach 30%.
- Postoperative traumatic hydrocele is common and usually resolves spontaneously.
- Injury to vas deferens or spermatic vessels
- Suture granuloma
- Hematoma
- Wound infection
- Recurrence

REFERENCES

CODES

ICD10

- N43.3 Hydrocele, unspecified
- N43.2 Other hydrocele
- P83.5 Congenital hydrocele

**CLINICAL PEARLS**

- A hydrocele can usually be diagnosed by physical exam and transillumination. If there is any concern for other underlying process, a formal US is recommended.
- Aspiration alone is not indicated as the primary treatment of a hydrocele due to high recurrence rate.
- Attempted aspiration of an unconfirmed hydrocele could lead to bowel injury in an undiagnosed inguinal hernia and should not be attempted.
- Expectant management of children with hydrocele until >2 years of age is acceptable to allow sufficient time for spontaneous resolution, decreasing the likelihood of an unnecessary procedure.
- In adults, surgical resection costs more and has more complications but has a much lower recurrence rate and a much higher patient satisfaction rate.
HYDROCEPHALUS, NORMAL PRESSURE
Dennis E. Hughes, DO, FAAFP, FACEP

BASICS

DESCRIPTION
- Normal pressure hydrocephalus (NPH) is a clinical triad of gait instability, incontinence, and dementia (mnemonic: wet, wobbly, wacky); originally described by Hakim in 1957
- Two forms of the disorder: idiopathic and obstructive (the latter usually due to physical insult—posttrauma, meningitis, or subarachnoid hemorrhage)
- Absence of papilledema on clinical exam and normal cerebrospinal fluid (CSF) pressures at lumbar puncture

ALERT
Idiopathic NPH (iNPH) primarily affects persons >60 years; extremely rare before 40 years

EPIDEMIOLOGY
- iNPH form primarily affects elderly, at least >40 years of age.
- Secondary form can occur at any age.
- Male = female
- Estimated to be a contributing factor in 6% of all cases of dementia

Incidence
Varies from 1.1–5.5% in various surrogate analysis of shunt data. Arriving at accurate data is hampered by uncertain diagnosis.

Prevalence
Ranges from 0.2% in the 70 to 79 years age group and increases to 5.9% in those 80 years and older. It is estimated that approximately 700,000 are affected in the United States (compared with 400,000 with multiple sclerosis) and 2,000,000 in Europe (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- Idiopathic form is a communicating hydrocephalus, a disorder of decreased CSF absorption (not overproduction). In iNPH, the leading theory suggests that poor venous compliance impairs the subarachnoid granulations’ ability to maintain baseline removal of CSF. In secondary NPH, scarring is likely.
- The result is a pressure gradient between the subarachnoid space and ventricular system.
- CSF production decreases in the face of an increased pressure set point (but still in excess of the amount of CSF absorbed).
- Elevated pressure distends ventricles and compresses the brain parenchyma.
- As a result of compression, there is an disruption of normal cerebral blood flow with resulting ischemic changes in the parenchymal vasculature leading to subsequent tissue damage and loss (2).
- Some believe that the idiopathic form is a result of persistently insufficient removal of CSF by immature subarachnoid granulations from childhood.
- Secondary NPH may result from the following:
- Head trauma (most common)
- Subarachnoid hemorrhage
- Resolved acute meningitis
- Chronic meningitis (tuberculosis, syphilis)
- Paget disease of the skull

**RISK FACTORS**
- Idiopathic risk is unknown (case reports suggest a possible genetic link but unsubstantiated).
- Secondary form is due to head trauma, subarachnoid hemorrhage, meningitis, or encephalitis.

**DIAGNOSIS**

Detailed history and careful examination is the key to early diagnosis.

**HISTORY**
- Insidious and usually progressive; gait instability usually manifests initially, followed by changes in mentation, and eventually, urinary incontinence.
- Behavioral changes noted in many cases: Depression, mania, and psychotic features in many cases precede the physical findings and respond poorly to usual treatment (1)[C].
- Difficulty with initiation of movement: Feet appear “glued to the floor.” Gait is wide-based, shuffling, and turning appears “en bloc.”
- Inattention, forgetfulness, and lack of spontaneity often are seen with the subcortical dementia of NPH.
- Urinary urgency initially, followed by lack of inhibition and then frank incontinence
  - A minimum duration of at least 3 to 6 months of symptoms and progression over time
  - A remote trauma or infection suggests secondary versus the idiopathic form.
  - A lack of psychiatric, neurologic, or other medical conditions to explain the symptoms (including structural reasons for CSF flow restriction)
  - Because memory impairment may be present, it is important to include a knowledgeable informant who is familiar with the patient’s premorbid state.
  - Frontal lobe function is affected disproportionately to the memory impairment (objective testing may lead to an early diagnosis).
  - Many exhibit symptoms of Parkinsonism such as bradykinesia and rigidity (3)[C].

**PHYSICAL EXAM**
- Decreased step height and length
- Reduced speed of walking (cadence)
- Widened standing base
- Swaying of trunk during walking
- Decreased fine motor speed and accuracy
- Recall impaired for recent events
- Impaired ability to do multistep tasks or interpret abstractions

**DIFFERENTIAL DIAGNOSIS**
- Alzheimer disease (may be a comorbid condition in as many as 75%)
- Parkinson disease
- Chronic alcoholism
● Intracranial infection
● Multi-infarct dementia
● Subdural hematoma
● Carcinomatous meningitis
● Collagen vascular disorders
● Depression
● Syphilis
● B₁₂ deficiency
● Urologic disorders
● Other hydrocephalus disorders

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Thyroid-stimulating hormone (TSH)
- Syphilis serology
- Complete blood count
- Serum B₁₂, folate
- Metabolic profile
- Blood alcohol, analysis for drugs of abuse
- Urinalysis
- CSF analysis, including an opening pressure <245 mm H₂O (a value greater than this rules out iNPH by definition)
- Imaging is essential (1)[C].
  - Either computed tomography or magnetic resonance imaging (MRI) (preferred imaging study) shows the ventriculomegaly (particularly lateral and 3rd ventricles) with preservation of the cerebral parenchyma (as opposed to ventricular enlargement seen in other forms of dementia where brain atrophy is present). A narrow subarachnoid space (“tight convexity”) was recently shown to correlate to probable or definite iNPH.
  - Use of T1 weighted MRI images and combining Evans Index (a measure of ventricular dilation) and the callosal angle gives good accuracy in differentiating NPH from other conditions (AUC=0.96) (4)[B].

**Diagnostic Procedures/Other**

CSF removal aids in the definitive diagnosis as well as predicting response to surgical treatment.

- High-volume (30 to 70 mL) CSF removal via spinal tap (“tap test”)
- Comparison of gait analysis before and after CSF removal should be performed within 24 hours (a ≥20% improvement indicates a positive test) especially when combined with coexisting executive function improvement. Testing should be done with a quantifiable gait scale (Berg Balance Scale, Timed Get UP and Go Test, etc.) (5)[B].

**TREATMENT**

**MEDICATION**

- No medication is significantly helpful.
- Use of carbonic anhydrase inhibitors (acetazolamide) with repeat lumbar punctures has
provided mild and transient relief but is only supported by anecdotal evidence.

- Use of levodopa to rule out Parkinson disease may be helpful (NPH will display little, if any, significant improvement to dopamine agonist).

**ISSUES FOR REFERRAL**

- Neurology or neurosurgical consultation is helpful in suspected cases when other reversible medical conditions are ruled out.
- Recent cohort studies have demonstrated clinical improvement after surgical shunts. Perimeters of urinary continence, gait stability, and cognitive scores all improved at 1 year postshunt.

**ADDITIONAL THERAPIES**

Gait training and use of ambulation assist devices, as indicated, but limited efficacy

**SURGERY/OTHER PROCEDURES**

- Current therapy is limited to placement of ventricle-peritoneal or ventricle-atrial shunt from a lateral ventricle tunneled subcutaneous and drained into the peritoneal cavity (or right atrium). Recent work demonstrated that use of a lumbar-peritoneal shunt to be noninferior, is technically easier, and associated with less complications (6)[B].
- Patients whose symptoms have been present for a shorter period (<2 years) have a greater chance of improvement with shunting. Age has not been shown to negatively affect response to shunting. Improvement has been seen in patients with symptoms present for many years and previously undiagnosed.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Usually only for planned surgical treatment

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Assessment and modification of environment for fall risks
- Evaluation for ability to operate a motor vehicle safely (if driving)

**Patient Monitoring**

- Repeat neuropsychological testing to evaluate the status of the dementia after treatment.
- Improvement in the incontinence and walking speed can also be objectively measured.

**PATIENT EDUCATION**

Information at: [https://www.ninds.nih.gov/Disorders/All-Disorders/Normal-Pressure-Hydrocephalus-Information-Page](https://www.ninds.nih.gov/Disorders/All-Disorders/Normal-Pressure-Hydrocephalus-Information-Page)

**PROGNOSIS**

Natural history is progressive deterioration. Patient’s axial skeletal stability worsens with inability to walk, stand, sit, or turn over in bed.

**COMPLICATIONS**

- In patients treated surgically, cerebral infarcts, hemorrhage, infection, and seizures (in addition to the usual surgical risks): all usual age-related illnesses (as NPH is a condition affecting
those age >65 years)
- Shunt malfunction (especially when symptoms recur after successful shunt placement)
- Falls due to gait instability
- Urinary tract infections
- Skin breakdown, pressure ulcers, infections as movement dysfunction progresses

REFERENCES

Algorithm: Ataxia

CODES

ICD10
- G91.2 (Idiopathic) normal pressure hydrocephalus
- G91.0 Communicating hydrocephalus
- G91.3 Post-traumatic hydrocephalus, unspecified

CLINICAL PEARLS

- Consider in unexplained dementia or behavioral change.
- Insidious and usually progressive; gait instability usually manifests initially, followed by changes in mentation, and eventually, urinary incontinence
- Poor prognosis without therapy
HYDRONEPHROSIS
Monzurul H Chowdhury, MD • Pang-Yen Fan, MD

BASICS

DESCRIPTION

• Hydronephrosis refers to a structural finding—dilatation of the renal calyces and pelvis.
  – May occur with urinary tract infection (UTI), vesicoureteral reflux (VUR), high urine output, or physiologic changes in pregnancy
  – Can be accompanied with hydroureter
  – Presentation varies from incidental finding to discovery during workup for UTI or for flank or abdominal pain, or for acute kidney injury.
• Hydronephrosis should not be used interchangeably with obstructive uropathy, which refers to the damage to renal parenchyma resulting from urinary tract obstruction (UTO).

EPIDEMIOLOGY

• The incidence is more common in men than women and in children than adults (congenital anomalies).
• Acute unilateral hydronephrosis is more common than bilateral.

ETIOLOGY AND PATHOPHYSIOLOGY

• Hydronephrosis develops with increased pressure in the urinary collecting system.
• Increased pressure can cause calyceal fornix rupture and urinary extravasation.
• Over time, pressures return to normal, but kidney function declines from intense renal vasoconstriction.
• With concomitant urinary infection, bacteria can enter the renal vasculature, resulting in sepsis.
• Hydronephrosis may be acute/chronic, partial/complete, and uni-/bilateral.
  – Intraluminal obstruction: calculi, sloughed renal papillae, blood clot, fungal ball
  – Intrinsic abnormality of the urinary collecting system: transitional cell carcinomas, benign prostatic hypertrophy, prostate cancer, congenital ureteropelvic junction (UPJ) obstruction, ureterocele, neurogenic bladder (functional obstruction), urethral stricture or tuberculosis (TB) (can cause ureteral narrowing)
  – Extrinsic compression of the urinary collecting system: extraneous malignancy (lymphoma, colon, cervix), aortic/iliac aneurysm, retroperitoneal fibrosis, uterine prolapse (15% affected), endometriosis, ovarian vein syndrome, IgG4-related disease
  – Transplant hydronephrosis: Consider BK virus infection.
• Hydronephrosis in transplanted kidney is more common than native kidneys, specifically in immediate posttransplant period. It is due to ureteral strictures and lymphoceles (ureteral compression and bladder dysfunction).
• VUR resulting in varying degrees of hydroureteronephrosis
• Hydronephrosis due to high urine output (e.g., diabetes insipidus, psychogenic polydipsia)
• Hydronephrosis of infection: due to bacterial toxins inhibiting smooth muscle contraction of the renal pelvis and ureter

Pediatric Considerations

• Antenatal hydronephrosis is diagnosed in 1–5% of pregnancies, usually by US, as early as the
12th to 14th week of gestation.
- Children with antenatal hydronephrosis are at greater risk of postnatal pathology.
- Postnatal evaluation begins with US exam; further studies, such as voiding cystourethrogram (VCUG), based on the severity of postnatal hydronephrosis
- In neonates, it is the most common cause of abdominal mass.
- Common etiologies in children are VUR, congenital UPJ obstruction, neurogenic bladder, and posterior urethral valves.
- Pediatric diagnostic algorithm differs from adult due to different differential diagnosis necessitating age-appropriate testing.

Pregnancy Considerations
- Physiologic hydronephrosis in pregnancy is more prominent on the right than left and can be seen in up to 80% of pregnant women.
- Dilatation is caused by hormonal effects, external compression from expanding uterus, and intrinsic changes in the ureteral wall.
- Despite high incidence, most cases are asymptomatic.
- If symptomatic and refractory to medical management, ureteric calculus should be considered and urinary infection must be excluded.

DIAGNOSIS

HISTORY
- Symptoms vary according to cause, chronicity, location, and degree of obstruction.
- Although often asymptomatic, hydronephrosis can be associated with pain ranging from vague, intermittent discomfort to severe renal colic.
- Nausea and vomiting may be associated with pain or infection.
- Fever, chills with coexisting infection
- Anuria, if complete obstruction of bilateral or a solitary kidney
- Polyuria may occur due to impaired urinary concentration in partial obstruction, or postobstructive diuresis.
- Symptoms of chronic kidney disease (CKD): anorexia, malaise, weight gain, edema, shortness of breath, mental state changes, tremors from long-standing obstruction
- Dietl crisis: sudden attack of flank pain due to distension of renal pelvis caused by rapid ingestion of large amount of liquid or kinking of a ureter, producing temporary occlusion of urine flow
- Symptoms of bladder outlet obstruction: weak urine stream, nocturia, straining to void, overflow incontinence, urgency, and frequency
- General medical and surgical history: malignancy (extrinsic compression), radiotherapy (ureteric stricture/fibrosis), surgery (iatrogenic obstruction), trauma (hematoma or fibrosis), gynecologic disease (endometriosis, ovarian masses, uterine prolapse), smoking (urothelial cancer), drugs (methysergide-induced retroperitoneal fibrosis)

PHYSICAL EXAM
- General signs
  - Volume overload (edema, rales, hypertension [HTN]) from renal failure
  - Diaphoresis, tachycardia, tachypnea with pain
– High-grade fever, if infection
  • Abdominal exam: CVA tenderness, palpable bladder, rarely palpable abdominal mass (may be visible, particularly in thin children)
  • Pelvic exam: pelvic mass, uterine prolapse, palpable enlarged prostate (cancer or benign), urethral meatal stenosis, phimosis

**DIAGNOSTIC TESTS & INTERPRETATION**

- Urinalysis with microscopy: hematuria, proteinuria, crystalluria, pyuria
- Midstream urine culture and sensitivity: Exclude UTI.
- Basic metabolic panel: Elevated urea and creatinine may indicate obstructive uropathy. Hyperkalemic nonanion gap metabolic acidosis may indicate type 4 distal RTA due to obstruction.
- CBC: anemia of CKD, leukocytosis; if infection, check platelet count prior to considering ureteral instrumentation.
- Prostate-specific antigen (PSA): adult males age >50 years or with abnormal digital rectal exam or bladder outlet obstruction signs or symptoms
- Urine cytology: for malignant cells in urothelial malignancies
- US and noncontrast CT scanning are effective in diagnosing presence and cause of obstruction in most cases.
- US: screening test of choice for hydronephrosis
  - Sensitivity 90%, specificity 84.5% compared with IVU. Does not assess function and rarely detects cause and level of obstruction. Degree of hydronephrosis does not correlate with duration or severity of the obstruction.
  - Advantages: detects renal parenchymal disease (decreased renal size, increased cortical echogenicity, cortical thinning, cysts); no exposure to radiation or contrast; safe in pregnancy, contrast allergy, and renal dysfunction
  - False-positive findings 15.5%: normal extrarenal pelvis, parapelvic cysts, VUR, excessive diuresis
  - False-negative findings 10%: dehydration, acute obstruction, calyceal dilatation misinterpreted as renal cortical cysts, and retroperitoneal fibrosis
- Noncontrast helical CT (NHCT): test of choice for suspected nephrolithiasis
  - Reported sensitivity 94–96%, specificity 94–100%. Stone is most commonly found at levels of ureteric luminal narrowing: UPJ, pelvic brim, and the vesicoureteric junction.
  - Typical findings in acute obstruction are hydronephrosis with hydroureter proximal to the level of obstruction, perinephric stranding, and renal swelling. If chronic, renal atrophy may be noted.
  - Advantages: no contrast exposure, time-saving, cost-effective, identifies extraurinary pathology (1)
  - Disadvantages: does not assess function or degree of obstruction; higher radiation exposure, although low radiation dose protocols have shown comparable accuracy
- DTPA or MAG-3 radionuclide renal scan (diuretic renal scintigraphy)
  - Indicated only for evaluation of hydronephrosis without apparent obstruction
  - Determines presence of true obstruction as well as total and split (right vs. left) renal function
  - Furosemide is given 20 minutes after the tracer and the T1/2 for the tracer’s washout is measured. T1/2; <10 minutes is unobstructed, >20 minutes is obstructed, and 10 to 20 minutes is equivocal; some experts consider <15 minutes normal.
Advantages: no contrast exposure, safe in contrast allergy and renal dysfunction
False-positive findings: delayed excretion due to renal failure, massive dilatation causing a water-reservoir effect of delayed excretion without obstruction
False-negative findings: dehydration or inadequate diuretic challenge

Multiphase contrast-enhanced CT
Nonenhanced phase detects stones and swelling.
Parenchymal phase demonstrates decreased enhancement of renal parenchyma with acute obstruction; can identify extrarrenal causes of obstruction and determine the relative glomerular filtration rate (GFR) of each kidney with accuracy equal to radionuclide renal scan
Delayed phase allows visualization of the collecting system and soft tissue filling defects (e.g., urothelial cancer).

Magnetic resonance urography (MRU): indicated when US and NHCT are nondiagnostic
Provides anatomic, functional, and prognostic information; sensitivity not superior to US or NHCT for nephrolithiasis (70%) but superior for soft tissue causes including strictures
Advantages: no radiation exposure, safe in pregnancy
Disadvantages: more expensive and time-consuming (35 minutes vs. 5 minutes) and less available compared with CT. Gadolinium is contraindicated in renal failure especially when GFR is <30 mL/min due to risk of nephrogenic systemic fibrosis.

Diagnostic Procedures/Other
Cystoscopy, retrograde pyelogram ± ureteroscopy, and biopsy are occasionally used to determine the cause of obstruction (e.g., small urothelial cancer missed on imaging) or to confirm a normal distal ureter prior to pyeloplasty. In addition, such procedures are often needed to establish a definitive pathologic diagnosis for mass lesions.

TREATMENT
GENERAL MEASURES
Medical treatment: correction of fluid and electrolyte abnormalities, pain control, antibiotics as an adjunct to drainage if infection present
Relief of obstruction: prompt drainage indicated in the presence of UTI, compromised renal function, or uncontrollable/persistent pain
  Bladder outlet obstruction: urethral or suprapubic catheter
  Ureteric obstruction: retrograde (cystoscopic) or antegrade (percutaneous) stenting (2)
VUR is often managed conservatively with antibiotics; surgical management required in severe cases in children or women of childbearing age
Medical expulsive therapy (MET) with α-blockers or calcium channel blockers indicated for urethral stones <10 mm in patients with controlled pain, no signs of sepsis, with good renal function (3)[C]

SURGERY/OTHER PROCEDURES
Hydronephrosis due to obstruction
  Congenital UPJ obstruction: Pyeloplasty (open or laparoscopic) and minimally invasive stricture incision (endopyelotomy) are used with comparable results.
  Nephrolithiasis: Extracorporeal shock wave lithotripsy (ESWL) is the initial treatment of
choice for management of impacted upper urethral stones ≤2 cm. Ureteroscopy with or without intracorporeal lithotripsy has lower retreatment but higher complication rates and longer hospital stay; ureteral stenting pre-ESWL or post-ureteroscopy associated with no additional benefit and more discomfort and morbidity (4)[A]

- Transitional cell cancer: nephroureterectomy
- Idiopathic retroperitoneal fibrosis: ureterolysis (frees ureters from inflammatory mass)
- Prostate disorders: various treatment modalities, including transurethral resection of the prostate (TURP) and radical prostatectomy

- Nonobstructed hydronephrosis
  - VUR: ureteric reimplantation, endoscopic suburethral injection

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Obstruction coexisting with infection (pyonephrosis) is a true urologic emergency requiring urgent drainage. Typically, this requires placement of percutaneous nephrostomy tube(s) because retrograde (cystoscopic) stenting is often difficult, but both are equally effective.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Serial monitoring of kidney function (electrolytes, BUN, and creatinine) and BP until renal function stabilizes. Frequency of monitoring depends on severity of renal dysfunction.
- Follow-up US after stabilization of renal function to assess for resolution of hydronephrosis. If hydronephrosis persists, consider diuretic radionuclide study to rule out persistent obstruction.

**PROGNOSIS**
- Recovery of renal function depends on etiology, presence or absence of UTI, and degree and duration of obstruction.
- Significant recovery can occur despite days of complete obstruction, although some irreversible injury may develop within 24 hours. Delays in therapy can lead to irreversible renal damage (5).
- Diagnostic testing is of poor predictive value. Course of incomplete obstruction is highly unpredictable.

**COMPLICATIONS**
- Urine stasis: increased risk of infection and stones formation
- Obstruction causes progressive atrophy of kidney with irreversible loss of function.
- Spontaneous rupture of a calyx may occur with urine extravasation in the perinephric space.
- Postobstructive diuresis: marked polyuria after relief of obstruction:
  - Caused mostly by fluid and solute overload but may be exacerbated by impaired renal tubular concentrating ability. Urine output may be >500 mL/hr.
  - Replace urine losses with hypotonic fluid (usually with 0.45% NaCl) and only enough to avoid volume depletion. Replacement of urine output with equal amounts of saline will perpetuate the diuresis.

**REFERENCES**

ADDITIONAL READING

CODES

ICD10
- N13.30 Unspecified hydronephrosis
- N13.39 Other hydronephrosis
- Q62.0 Congenital hydronephrosis

CLINICAL PEARLS

- US and noncontrast CT identify most causes of hydronephrosis.
- Relief of obstruction, when present, is the primary treatment.
HYPERCHOLESTEROLEMIA
Michelle Nelson, MD ● Egle Klugiene, MD

BASICS

DESCRIPTION
● Elevated cholesterol is considered a significant risk factor for atherosclerotic cardiovascular disease (ASCVD), although the relationship is not simple.
● Lipoprotein subtypes:
  – Low-density lipoproteins (LDL): atherogenic; primary target of therapy
  – High-density lipoproteins (HDL): atheroprotective
  – Triglycerides (TG)
● System(s) affected: cardiovascular (CV)

EPIDEMIOLOGY
● 29% of U.S. adults > 20 years old have total cholesterol levels greater than 200 mg/dL.
● 7% of U.S. children and adolescents between the ages of 6 and 19 years have high total cholesterol.

Prevalence
Disease incidence and prevalence increases with age.

ETIOLOGY AND PATHOPHYSIOLOGY
● Pathophysiology
  – Deposition of cholesterol in vascular walls creates fatty streaks that become fibrous plaques.
  – Inflammation causes plaque instability, leading to plaque rupture.
  – Atherosclerosis, inflammation, and vascular reactivity are complex processes not explained by cholesterol alone.
● Etiology of hypercholesterolemia
  – Primary: genetic causes (familial dyslipidemia)
  – Secondary: obesity, diet, excessive alcohol intake, hypothyroidism, diabetes, inflammatory disease (systemic lupus erythematosus, juvenile rheumatoid arthritis) liver disease, nephrotic syndrome, chronic renal failure, medications (thiazide diuretics, carbamazepine, cyclosporine, progestins, anabolic steroids, corticosteroids, protease inhibitors, antipsychotics, isotretinoin)

Genetics
● Familial hypercholesterolemia (FH)
  – Elevated LDL levels from birth
  – Prevalence is 1:500 in the United States.
  – Predisposition to atherosclerotic disease in early adulthood and high coronary heart disease risk at younger ages (40s and 50s)
  – Tendon xanthomas on Achilles and extensor tendons of the hands are common.
  – Early lipid-lowering drug therapy has been shown to reduce ASCVD risk.
● Early cholesterol testing of first-degree relatives is recommended and beneficial.
RISK FACTORS
Obesity (body mass index [BMI] >30 kg/m²), physical inactivity, heredity, cigarette smoking, excessive alcohol use. Unclear relationship between diet rich in saturated fat and hypercholesterolemia. The relationship of diet to disease is very complex and is not explained by how much cholesterol is present in an individual’s diet.

GENERAL PREVENTION
- Regular physical activity
- Weight control (see “Ongoing Care”)

COMMONLY ASSOCIATED CONDITIONS
Hypertension (HTN), diabetes mellitus (DM), obesity

DIAGNOSIS
Screening recommendations:
- U.S. Preventive Services Task Force (USPSTF) (1)[A]: TC and HDL cholesterol (HDL-C) every 5 years
  - Men and women ≥40 years
  - No recommendation for or against screening in adults aged 21 to 39 years
  - No recommendation for or against screening in children and adolescents
- American Diabetes Association: yearly dyslipidemia screening for patients with diabetes

Pediatric Considerations
- National Heart, Lung, and Blood Institute (NHLBI): Recommend universal lipid screening for all children between 9 and 11 years and between 17 and 21 years old.
- This remains controversial because of the absence of data showing improved outcomes and concern about potential harms. Selective screening of children with FH of premature coronary artery disease is not controversial.
- USPSTF: insufficient evidence to recommend for or against screening children and adolescents.

HISTORY
- Review possible secondary etiologies (see “Etiology and Pathophysiology”).
- Review medications that may alter lipid levels.
- Assess other ASCVD risk factors.

PHYSICAL EXAM
Nonspecific findings; may calculate BMI and examine for xanthomas

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Lipid panel (fasting labs do not significantly affect lab values): TC, LDL, HDL, TG: LDL is usually a calculated value and is accurate if TG <350 mg/dL. Nonfasting labs are an even better estimate of cardiovascular risk (2).
- Consider genetic etiology in very high LDL (>190 mg/dL) or TG (>500 mg/dL).
TREATMENT

**ALERT**

Multiple differing guidelines exist. Patient-centered decision. The 2018 American College of Cardiology/American Heart Association (ACC/AHA) cholesterol guidelines return to targeting LDL goals. ACC/AHA and USPSTF guidelines recommend statin therapy based on patients’ risk of an ASCVD event. Efficacy of statin medication for reduction in myocardial infarction (MI) and death is likely due to mechanisms other than cholesterol lowering alone. Risk stratifying patients should be reserved for primary prevention as patients with established CV disease should be considered high risk (secondary prevention).

- United States: ACC/AHA cholesterol guidelines (3)
  - Four groups benefit from statin therapy:
    - Primary elevation of LDL-C >190 mg/dL: high-intensity statin
    - Diabetics (type 1 or 2) ages 40 to 75 years with LDL-C >70 mg/dL: moderate-intensity statin
      - 10-year ASCVD risk <5%: lifestyle modifications with Mediterranean diet and exercise
      - 10-year ASCVD risk 5–7.5%: moderate-intensity statin, discuss with patient
      - 10-year ASCVD risk 7.5–20%: moderate-intensity statin with goal to reduce LDL-C by 30–49%
      - 10 year ASCVD risk >20%: high-intensity statin with goal to reduce LDL-C >50%
    - Secondary ASCVD prevention
      - Age < 75 years: High intensity statin with goal to reduce LDL-C >50%. Add ezetimibe if LDL is >70 mg/dL after maximal statin therapy in very high-risk ASCVD patients.*
      - Age > 75 years: Moderate or high-intensity statin as tolerated
  - *Definition of very high-risk ASCVD is at least one major ASCVD event and multiple high-risk conditions:
    - Major ASCVD events
      - Acute coronary syndrome or history of MI
      - History of ischemic stroke
      - Symptomatic peripheral arterial disease
    - High-risk conditions
      - Age >65 years
      - Heterozygous familial hypercholesterolemia
      - History of CABG or PCI
      - Diabetes Mellitus
      - Hypertension
      - Chronic kidney disease
      - Current smoker
      - History of congestive heart failure
      - LDL-C >100 mg/dL despite maximum medical therapy
  - Significant controversy over threshold calculated risk with which to treat patients:
    - Concern that Pooled Cohort Equations significantly overestimates ASCVD risk
    - Concern for significant overtreatment: One study shows 96% of men and 66% of women
>55 years of age on statins based on recommendations.

- United States: USPSTF statin recommendations (1)[A]
  - Adults aged 40 to 75 years with no history of CVD, one or more CVD risk factors, and a calculated 10-year CVD event risk of 10% or greater: low to moderate dose statin
  - Adults aged 40 to 75 years with no history of CVD, one or more CVD risk factors, and a calculated 10-year CVD event risk of 7.5–10%: low to moderate dose statin
  - Adults 76 years and older with no history of CVD: insufficient evidence to make recommendation

- Many patients treated and medications used in the United States than elsewhere in the world without substantial evidence for improved outcomes

- United Kingdom: National Institute for Health and Care Excellence (NICE) cholesterol guidelines
  - 10-year risk to be calculated using QRISK2: [http://www.qrisk.org/](http://www.qrisk.org/)
  - If 10-year risk of CVD >10% and no history of CVD, start atorvastatin 20 mg.
  - If 10-year risk of CVD >10% in presence of known CVD, start atorvastatin 80 mg.
  - If estimated glomerular filtration rate <60 or type I diabetes, start atorvastatin 20 mg regardless of risk.
  - Check nonfasting lipid panel before treatment initiation and at 3 months of treatment: goal reduction of 40% in non–HDL-C

- U.S. Veterans Affairs 2014 Guideline advises moderate-dose statin for 10-year CVD risk >12%, or LDL-C ≥190, or DM with HTN or smoking.

**ALERT**

Elevated serum TG

- If >500 mg/dL, TG lowering becomes primary target until TG <500 mg/dL to prevent acute pancreatitis. Statin therapy is usually recommended as treatment unless TGs remain >500 mg/dL after statin added. Fibrates may be used cautiously with statins (increased risk of rhabdomyolysis).

**MEDICATION**

- Therapeutic lifestyle changes are cornerstone therapies to be attempted before drug therapy (diet and regular exercise; see “Ongoing Care”).

- Available data do not support initiation of statin therapy for primary prevention in most adults age >75 years (ALLHAT-LLT and other trials).

- Check lipid panel 4 to 12 weeks after starting medication to evaluate response/compliance.
  - High-intensity statin: should lower LDL-C >50%
  - Moderate-intensity statin: should lower LDL-C 30–50%
  - Subsequent monitoring not generally indicated unless question of patient adherence

**First Line**

HMG-CoA reductase inhibitors (statins)

- Categorized based on intensity
  - High intensity (Reduces LDL-C by >50%)
    - Atorvastatin: 40 to 80 mg/day
    - Rosuvastatin: 20 to 40 mg/day
  - Moderate intensity (Reduces LDL-C by 30% to 49%)
    - Atorvastatin: 10 to 20 mg/day
- Rosuvastatin: 5 to 10 mg/day
- Simvastatin: 20 to 40 mg/day
- Pravastatin: 40 to 80 mg/day
- Lovastatin: 40 mg/day
- Fluvastatin XL: 80 mg/day
- Fluvastatin: 40 mg BID
- Pitavastatin: 2 to 4 mg/day

  - Low intensity (Reduces LDL-C by <30%)
    - Simvastatin: 10 mg/day
    - Pravastatin: 10 to 20 mg/day
    - Lovastatin: 20 mg/day
    - Fluvastatin: 20 to 40 mg/day
    - Pitavastatin: 1 mg/day

- To be taken in the evening or at bedtime for best effect because majority of cholesterol synthesis appears to occur at night
- Effect is greatest in lowering LDL-C; shown to decrease coronary heart disease incidence and all-cause mortality (1), although number needed to treat may be very high in primary prevention, depending on risk
- Contraindications: pregnancy, lactation, or active liver disease
- Drug interactions: cyclosporine, macrolide antibiotics, various antifungal agents, HIV protease inhibitors, hepatitis C protease inhibitors, fibrates/nicotinic acid (to be used with caution)
- Adverse reactions:
  - Mild myalgia is common.
  - Liver transaminase elevations: alanine aminotransferase (ALT) before therapy to establish baseline; if ALT >3 times upper limit of normal, do not start statin; routine monitoring is not recommended.
  - Association with increased cases of diabetes: 0.1 excess cases of diabetes per 100 persons on moderate-intensity statin and 0.3 excess cases per 100 persons on high-intensity statin
  - Myopathies (considered rare but not well studied):
    - Creatine kinase (CK) baseline reasonable for those at increased risk for adverse muscle events; routine monitoring not recommended
    - Instruct patients to report new onset of myalgias or weakness.
    - If myopathy or rhabdomyolysis is suspected, discontinue statin and draw serum CK, creatinine, and urine analysis.
    - Can rechallenge statin at lower dose or different type after resolution of symptoms
  - Statin intolerance
    - Consider use of a different statin.
    - Dose reduction
    - Alternate day therapy
    - A majority of patients who had previously discontinued statins due to side effects are able to restart the same or another statin and tolerate them.

**ALERT**
Food and Drug Administration alert: Simvastatin should not be prescribed at 80 mg/day doses due to increased risk of myopathy. Patients who have been at this drug dosage for >1 year can continue if no signs of myopathy. Dose restrictions to reduce myopathy risk include the following:
Do not exceed simvastatin 10 mg/day with amiodarone, verapamil, and diltiazem.
Do not exceed simvastatin 20 mg/day with amlodipine and ranolazine.

**ALERT**
Avoid grapefruit juice with statins. It increases the risk of statin myopathy.

**Pregnancy Considerations**
- Statins contraindicated during pregnancy: Class X
- Lactation: possibly unsafe

**Second Line**
- Second-line drugs are now recommended in primary prevention if LDL-C is >70 mg/dL on maximal statin therapy (2).
- If LDL-C is still not at goal with maximum statin therapy and ezetimibe, then consider adding proprotein convertase subtilisin/kexin type 9 (PCSK9) inhibitors. Some benefit shown in secondary prevention. Long-term studies demonstrating benefit and harms not yet complete.
- Ezetimibe
  - Can be taken by itself or in combination with a statin: monotherapy (10 mg/day) or ezetimibe/simvastatin (10/10, 10/20, 10/40)
  - Effect: lowers LDL-C; one randomized controlled trial shows combination therapy with statin has small benefit in reducing CV events and CV-related mortality after acute coronary syndromes.
  - Adverse reactions: generally well tolerated
- Fibrates
  - Types: gemfibrozil 600 mg BID, fenofibrate
  - Effect: most effective in lowering TG with moderate effect in lowering LDL and raising HDL. More recent studies fail to show benefit in most patients.
  - Contraindications: severe hepatic or renal insufficiency
  - Possible interactions: potentiates effects of warfarin and oral hypoglycemic agents
  - Adverse reactions: gastrointestinal (GI) complaints; increased likelihood of gallstones
- Niacin raises HDL but no evidence for improved outcomes; should no longer be used in routine practice
- Bile acid sequestrant (e.g., cholestyramine) causes significant GI side effects, no evidence for improved outcomes, rarely used.
- Proprotein convertase subtilisin/kexin type 9 (PCSK9) inhibitors (e.g., alirocumab, evolocumab)
  - Monoclonal antibody requiring SC injections every 2 to 4 weeks
  - Current evidence shows decreased incidence of CVD in secondary prevention without affecting incidence of all-cause mortality; active research ongoing
  - Very expensive

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Omega-3 fatty acids and fish oil intake:
  - Sources—fatty fish, plants (flaxseed, canola oil, soybean oil, nuts)
  - Effect—mainly lowers TG level (dose dependent) but has some benefit in lowering LDL and raising HDL, although overall CV benefit and mortality reduction is uncertain
  - Fish oil (no established benefit in outcomes). Advise patients instead to eat fish.
- β-Sitosterols and red yeast rice (contains small amount of natural lovastatin analogue) can
reduce TC and LDL. However, there is significant variability across commercial preparations.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Exercise: sustained exercise for 150 minutes per week: increases HDL, lowers TC, and helps control weight

**Patient Monitoring**
- Routine monitoring of lipid levels is controversial.
- Routine monitoring of liver function tests is no longer recommended if initial ALT is within normal range.

**DIET**
Mediterranean diet, which is high in legumes, fruits, vegetables, nuts, fish, and olive oil, is thought to reduce the risk of cardiovascular disease.

**CODES**

**ICD10**
E78.0 Pure hypercholesterolemia
CLINICAL PEARLS

Diet, particularly the Mediterranean diet, and exercise should be tried before pharmaceutical interventions.
HYPEREMESIS GRAVIDARUM
John M. Doan, DO

BASICS

DESCRIPTION
- Hyperemesis gravidarum is intractable vomiting in a pregnant woman that interferes with fluid and electrolyte balance as well as nutrition:
  - Usually associated with the first 8 to 20 weeks of pregnancy
  - Believed to have biomedical and behavioral aspects
  - Associated with high estrogen and human chorionic gonadotropin (hCG) levels
  - Symptoms usually begin ~2 weeks after first missed period and normally resolves by the 20th week
- System(s) affected: endocrine/metabolic; gastrointestinal; reproductive
- Synonym(s): morning sickness

Pregnancy Considerations
While morning sickness is common during pregnancy, hyperemesis gravidarum is a rare condition.

EPIDEMIOLOGY

Incidence
Hyperemesis gravidarum occurs in 1–2% of pregnancies.

Prevalence
Hyperemesis gravidarum is the most common cause of hospitalization in the first half of pregnancy and the second most common cause of hospitalization of all pregnant women.

ETIOLOGY AND PATHOPHYSIOLOGY

Etiology unknown. Proposed influences include:
- Hyperthyroidism
- Hyperparathyroidism
- Pregnancy hormones
- Liver dysfunction
- Autonomic nervous system dysfunction
- Central nervous system (CNS) neoplasm
- Addison disease
- Possible psychological factors

Genetics
Increased risk if maternal family history of hyperemesis gravidarum

RISK FACTORS
- Nulliparity
- Multiple gestations
- History of migraines
- History of motion sickness
- Black or Asian women
- Gestational trophoblastic disease
- Fetus with trisomy 21
- Female fetus
- Possible association with Helicobacter pylori infection

**GENERAL PREVENTION**
Anticipatory guidance regarding dietary habits to avoid dehydration and nutritional depletion
- Small, frequent meals
- Avoiding an overly empty or full stomach

**Pregnancy Considerations**
- 2% of pregnancies have electrolyte disturbances.
- 50% of pregnancies have at least some gastrointestinal disturbance.

**COMMONLY ASSOCIATED CONDITIONS**
Hyperthyroidism

**DIAGNOSIS**

**HISTORY**
- Nausea
- Vomiting with retching more than 3 times per day
- Decreased urine output
- Fatigue
- Dizziness with standing
- Poor appetite

**PHYSICAL EXAM**
- >5% weight loss from pre-pregnancy weight
- Signs of dehydration, such as orthostatic hypotension, large ketonuria

**DIFFERENTIAL DIAGNOSIS**
Other common causes of vomiting must be considered:
- Gastroenteritis
- Gastritis
- Reflux esophagitis
- Peptic ulcer disease
- Cholelithiasis
- Cholecystitis
- Pyelonephritis
- Anxiety
- Hyperparathyroidism
- H. pylori infection

**DIAGNOSTIC TESTS & INTERPRETATION**
Initial Tests (lab, imaging)
Urinalysis: may see glucosuria, albuminuria, granular casts, and hematuria (rare); ketosis more common
- Thyroid-stimulating hormone (TSH), T4
- Electrolytes, blood urea nitrogen, creatinine:
  - Electrolyte abnormalities due to nausea and vomiting and subsequent dehydration
  - Acidosis
- Calcium
- Albumin

Imaging is only indicated if there is concern for hydatidiform mole or multiple gestation, in which case ultrasound may be obtained.

**Diagnostic Procedures/Other**
Indicated only if it is necessary to rule out other diagnoses, as listed in the following section

### TREATMENT

Pyridoxine and doxylamine (pregnancy Category A) are first-line treatments for hyperemesis gravidarum (1)[C]. This is followed by metoclopramide or ondansetron (pregnancy Category B) and then prochlorperazine (pregnancy Category C), methylprednisolone (pregnancy Category C), or promethazine (pregnancy Category C).

**GENERAL MEASURES**
- IV fluids, either normal saline or 5% dextrose normal saline (with consideration for potential thiamine deficiency). Repeat if there is a recurrence of symptoms following initial improvement.
- For severe cases, consider PO thiamine 25 to 50 mg TID or IV 100 mg in 100 mL of normal saline over 30 minutes once weekly and potential parental nutrition if needed.
- Ondansetron carries an Food and Drug Administration warning regarding concerns for QT prolongation, but this is in the setting of high-dose IV administration and in patients with heart disease. It has unclear risk in the setting of pregnancy. The majority of the current studies appear to show no increased risk of fetal malformation with the use of ondansetron, but this is still an area of controversy.

**MEDICATION**
- Pyridoxine (vitamin B₆) 25 mg PO or IV every 8 hours, max dose of 200 mg/day
- Antihistamines (e.g., diphenhydramine [25 to 50 mg q4–6h] or doxylamine [12.5 mg PO BID]) (2)[C]
- Combination product Diclegis (sustained-release pyridoxine 10 mg and doxylamine 10 mg) dosed (start 2 tabs PO qhs; if symptoms persist, increase to 1 tab in am and 2 hs; if symptoms still persist, take 1 tab q am, 1 midday, and 2 hs; max 4 tablets/day)
- Phenothiazines (e.g., promethazine or prochlorperazine):
  - Precautions: Phenothiazines are associated with prolonged jaundice, extrapyramidal effects, and hyper- or hyporeflexia in newborns.
  - Meclizine 25 mg PO q6h
- Metoclopramide 10 mg PO q6–8h
- Methylprednisolone 16 mg PO/IV q8h for 2 to 3 days and then taper over 2 weeks if initial 3-day treatment is effective; reserved for severe cases with unclear benefit
Ondansetron 4 to 8 mg PO q8h

Pregnancy Considerations
All medications taken during pregnancy should balance the risks and benefits both to the mother and the fetus.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Ginger 350 mg PO TID may help (3)[A].
- Evidence is mixed regarding the impact of acupressure and acupuncture in treating hyperemesis gravidarum. Acupressure bands at the Neiguan point are effective adjuvant treatment in severe hyperemesis (4)[A].
- Medical hypnosis may be a helpful adjunct to the typical medical treatment regimen, but further study is needed.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Typically outpatient therapy
- In some severe cases, parenteral therapy in the hospital or at home may be required.
- Enteral volume and nutrition repletion may be indicated, but early enteral tube feeding does not improve maternal or perinatal outcomes (5)[A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Activity as tolerated after improvement
- Overall quality of life and future fertility plans can be impacted by severity of nausea and vomiting (6)[B].

Patient Monitoring
- In severe cases, follow-up on a daily basis for weight monitoring
- Special attention should be given to monitor for ketosis, hypokalemia, or acid–base disturbances due to hyperemesis.

DIET
- Bland or liquid diet as tolerated
- For outpatient: a diet rich in carbohydrates and protein, such as fruit, cheese, cottage cheese, eggs, beef, poultry, vegetables, toast, crackers, rice. Patients should avoid spicy meals and high-fat foods. Encourage small amounts at a time every 1 to 2 hours.

PATIENT EDUCATION
- Attention should be given to psychosocial issues, such as possible ambivalence about the pregnancy.
- Patients should be instructed to take small amounts of fluid frequently to avoid volume depletion.
- Avoid individual foods known to be irritating to the patient.
- Wet-to-dry nutrients (sherbet, broth, gelatin to dry crackers, toast)

PROGNOSIS
- Self-limited illness with good prognosis if patient’s weight is maintained at >95% of
prepregnancy weight

- With complication of hemorrhagic retinitis, mortality rate of pregnant patient is 50%.

**COMPLICATIONS**

- Patients with >5% weight loss are associated with intrauterine growth retardation and fetal anomalies.
- Poor weight gain is associated with slightly increased risk for small for gestational age infant <2,500 g and premature birth <37 weeks (7)[A].
- Hemorrhagic retinitis
- Liver damage
- CNS deterioration, Wernicke encephalopathy secondary to thiamine deficiency, coma

**REFERENCES**

**ADDITIONAL READING**

2018;31(18):2492–2505.

CODES

ICD10
- O21.9 Vomiting of pregnancy, unspecified
- O21.0 Mild hyperemesis gravidarum
- O21.1 Hyperemesis gravidarum with metabolic disturbance

CLINICAL PEARLS
- Do not allow patients to become volume depleted. Once this occurs, it is more difficult to interrupt the process.
- Do not be hesitant to use medications to assist the patient, as this may help avoid volume depletion.
- Consider secondary causes of hyperemesis if it develops after 12 weeks of gestation.
BASICS

DESCRIPTION

- Hyperkalemia is a common electrolyte disorder that may be defined as a plasma potassium (K) concentration >5.5 mEq/L (>5 mmol/L).
- Hyperkalemia depresses cardiac conduction and can lead to fatal arrhythmias.
- Normal K regulation
  - Ingested K enters portal circulation; pancreas releases insulin in response. Insulin facilitates K entry into cells.
  - K in renal circulation causes renin release from juxtaglomerular cells, leading to activation of angiotensin I, which is converted to angiotensin II in lungs. Angiotensin II acts in adrenal zona glomerulosa to stimulate aldosterone secretion. Aldosterone, at the renal collecting ducts, causes K to be excreted and sodium to be retained.
- Four major causes
  - Increased load: either endogenous from tissue release or exogenous from a high intake, usually in association with decreased excretion
  - Decreased excretion: due to decreased glomerular filtration rate or impaired aldosterone secretion
  - Cellular redistribution: shifts from intracellular space (majority of K is intracellular) to extracellular space
  - Pseudohyperkalemia: related to red cell lysis during collection or transport of blood sample, thrombocytosis, or leukocytosis

Geriatric Considerations

Increased risk for hyperkalemia because of decreases in renin and aldosterone as well as comorbid conditions

EPIDEMIOLOGY

Incidence

- There is much variation in reported incidence rates of hyperkalemia.
- Incidence became increasingly more common when potassium is measured more often and is higher in patients of older age, male sex, worse kidney function, comorbidities, and use of renin angiotensin-aldosterone system inhibitors (1).

Prevalence

- 1–10% of hospitalized patients
- 2–3% in general population but as high as 50% in patients with chronic kidney disease (2)
- Predominant sex: male = female
- No age-related predilection

ETIOLOGY AND PATHOPHYSIOLOGY

- Pseudohyperkalemia
  - Hemolysis of red cells in phlebotomy tube (spurious result is most common)
- Thrombolysis
- Leukocytosis
- Thrombocytosis
- Hereditary spherocytosis
- Infectious mononucleosis
- Traumatic venipuncture or fist clenching during phlebotomy (spurious result)
- Familial pseudohyperkalemia

- Transcellular shift (redistribution)
  - Metabolic acidosis
  - Insulin deficiency
  - Hyperglycemia (diabetic ketoacidosis or hyperosmolar hyperglycemic state)
  - Tissue damage (rhabdomyolysis, burns, trauma)
  - Tumor lysis syndrome
  - Cocaine abuse
  - Exercise with heavy sweating
  - Mannitol

- Impaired K excretion
  - Renal insufficiency/failure
  - Addison disease
  - Mineralocorticoid deficiency
  - Primary hyporeninemia, primary hypoaldosteronism
  - Type IV renal tubular acidosis (hyporeninemic hypoaldosteronism)
  - Obstructive uropathy
  - Cirrhosis
  - Congestive heart failure
  - Sickle cell disease
  - Amyloidosis
  - Systemic lupus erythematosus

- Medication-induced
  - Excess K supplementation
  - Statins
  - ACE inhibitors
  - Angiotensin receptor blockers
  - β-Blockers
  - Cyclosporine
  - Digoxin toxicity
  - Ethinyl estradiol/drospirenone
  - Heparin
  - Lithium
  - NSAIDs
  - Penicillin G potassium
  - Pentamidine
  - Spironolactone
  - Succinylcholine
  - Tacrolimus
  - Trimethoprim, particularly with other medications associated with hyperkalemia (3)
Genetics
Associated with some inherited diseases and conditions
- Familial hyperkalemic periodic paralysis
- Congenital adrenal hyperplasia

RISK FACTORS
- Impaired renal excretion of K
- Acidemia
- Massive cell breakdown (rhabdomyolysis, burns, trauma)
- Use of K-sparing diuretics
- Excess K supplementation
- Comorbid conditions: chronic kidney disease, diabetes, heart failure, liver disease

GENERAL PREVENTION
Low K diet and oral supplement compliance in those at risk

COMMONLY ASSOCIATED CONDITIONS
- Chronic kidney disease (CKD)
- End-stage renal disease (ESRD)
- Congestive heart failure (CHF)
- Myocardial infarction (MI)
- Rhabdomyolysis
- Liver disease
- Use of medications such as ACE inhibitors or angiotensin II receptor blockers

DIAGNOSIS
Serum potassium level greater than the normal range (3.5–5.0 mEq/L)

HISTORY
- Neuromuscular cramps
- Abdominal pain
- Palpitations
- Myalgias
- Numbness
- Muscle weakness or paralysis

PHYSICAL EXAM
- Decreased deep tendon reflexes
- Flaccid paralysis of extremities

DIAGNOSTIC TESTS & INTERPRETATION
- Serum electrolytes
- Renal function: BUN, creatinine
- Urinalysis: K, creatinine, osmoles (to calculate fractional excretion of K and transtubular K gradient; both assess renal handling of K)
- Disorders that may alter lab results
  - Acidemia: K shifts from the intracellular to extracellular space
– Insulin deficiency
– Hemolysis of sample
• Cortisol, aldosterone, and renin levels to check for mineralocorticoid deficiency when other causes are ruled out

**Diagnostic Procedures/Other**
ECG abnormalities usually occur when K ≥7 mEq/L
• Peaked T wave with shortened QT interval in precordial leads (most common, usually earliest ECG change; however, neither sensitive nor specific) (4)[C]
• Lengthening of PR interval
• Loss of P wave
• Widened QRS
• Sine wave at very high K
• Can eventually lead to arrhythmias including bradycardia, ventricular fibrillation, and asystole

---

**TREATMENT**

**MEDICATION**
- Stabilize myocardial membranes. Initial treatment with calcium gluconate IV 1,000 mg (10 mL of 10% solution) over 2 to 3 minutes (3)[A]
  - With constant cardiac monitoring
  - Can repeat after 5 minutes if needed
  - Effect begins within minutes but only lasts 30 to 60 minutes and should be used in conjunction with definitive therapies
  - Can also use calcium chloride (3 times as concentrated; however, central or deep vein administration is necessary to avoid tissue necrosis).
- Drive extracellular K into cells
  - Nebulized albuterol (at 10 to 20 mg/4 mL saline >10 minutes—4 to 8 times bronchodilation dose) and other β-agonists have an additive effect with insulin and glucose (3)[B].
  - Dextrose 50% 1 amp (if plasma glucose <250 mg/dL) and insulin 10 U IV may drive K intracellularly but does not decrease total body K and may result in hypoglycemia (close monitoring advised, especially 1 to 2 hours postinjection) (3)[B].
  - Sodium bicarbonate not routinely recommended but some possible benefits in severe metabolic acidosis (5)[C]
- Remove excess K from body.
  - Cation exchange resins definitive treatment but require several doses and best used with rapidly acting transient therapies above and when dialysis not readily available (6)[A]
  - Gastrointestinal cation exchangers, patiromer calcium (Veltassa), sodium polystyrene sulfonate (Kayexalate), and zirconium cyclosilicate bind K in the intestinal tract. Patiromer in particular is favored for improved tolerance and decreased side effects in both acute and chronic settings (7)[C].
  - Patiromer calcium (Veltassa): 8.4 g PO daily (dose may vary 4.2 to 16.8 g BID in studies)
    - This requires ~7 to 24 hours to lower K. This may be repeated q12h, if necessary (8)[C].
  - Sodium polystyrene sulfonate (Kayexalate): 15 g PO or 30 g rectally
    - This requires 1 to 4 hours to lower K. This may be repeated q6h, if necessary.
    - Enema has faster effect than PO (3)[C].
Hemodialysis is the definitive therapy when other measures are not effective. This may be required particularly when conditions, such as digitalis toxicity, rhabdomyolysis, end-stage renal disease, severe chronic kidney disease, or acute kidney injury, are present; should watch for postdialysis rebound [3][A].

Little clinical evidence for the use of diuretics (loop and thiazides); however, can consider for control of chronic hyperkalemia [3][B].

**Alert**
- Sodium polystyrene sulfonate (Kayexalate) provides a sodium load that may exacerbate fluid overload in patients with cardiac or renal failure.
- Avoid potassium polystyrene sulfonate use in patients who are postoperative or with a bowel obstruction or ileus due to high risk of intestinal necrosis.
- Rapid administration of calcium in patients with suspected digitalis toxicity may result in a fatal dysrhythmia. Calcium should be administered slowly over 20 to 30 minutes in 5% dextrose with extreme caution. Preferred therapy is digoxin-specific antibody fragments.

**Additional Therapies**
Mineralocorticoid replacement [9]
- If the patient does not have a contraindication (greater than stage 1 HTN, volume overload, history of heart failure) to mineralocorticoid administration then
  - Consider a trial of fludrocortisone 0.1 mg daily × 3–5 days [9] (in patients with moderately advanced CKD consider maintaining or increasing diuretics in tandem with the assistance of nephrology consulting service).

**Admission, Inpatient, and Nursing Considerations**
- If hyperkalemia is severe, treat first and then do diagnostic investigations.
- Consider early consultation of nephrologist.
- IV calcium to stabilize myocardium (caution in setting of digoxin toxicity/digoxin induced hyperkalemia, as this treatment can induce heart block).
- Insulin (usually 10 U IV, given with 50 mL of 50% glucose [if serum glucose <250 mg/dL] to avoid hypoglycemia); consider repeating if elevation persists.
- Inhaled β₂-agonist (nebulized albuterol)
- Discontinue any medications that may increase K (e.g., K-sparing diuretics, exogenous K).
- Admit for cardiac monitoring if ECG changes are present or if K is >6 mEq/L (6 mmol/L).

**Ongoing Care**

**Follow-Up Recommendations**

**Patient Monitoring**
- Reduction of plasma K should begin within the first hour of treatment initiation.
- Serum K levels should be rechecked every 2 to 4 hours until the patient has stabilized, and recurrent hyperkalemia is no longer a threat.
- Identification and elimination of possible causes and risk factors for hyperkalemia are essential.

**Diet**
Recommend ≤80 mEq (≤80 mmol) of K per 24 hours. Many foods contain K. Those that are particularly high in K (>6.4 mEq/serving) include bananas, orange juice, other citrus fruits and their juices, figs, molasses, seaweed, dried fruits, nuts, avocados, lima beans, bran, tomatoes, tomato juice, cantaloupe, honeydew melon, peaches, potatoes, and salt substitutes. Multiple herbal medications can also increase K levels, including alfalfa, dandelion, horsetail nettle, milkweed, hawthorn berries, toad skin, oleander, foxglove, and ginseng.

PATIENT EDUCATION
Consult with a dietitian about a low-K diet.

PROGNOSIS
- Associated with poor prognosis in patients with heart failure and chronic kidney disease
- Associated with poor prognosis in disaster medicine; with trauma, tissue necrosis, K$^+$ supplementation, metabolic acidosis; if calcium gluconate administered for treatment of hyperkalemia; if AKI; or if prolonged duration of hyperkalemia (5)

COMPLICATIONS
- Life-threatening cardiac arrhythmias
- Hypokalemia
- Potential complications of the use of ion-exchange resins for the treatment of hyperkalemia include volume overload and intestinal necrosis (7)[C].

REFERENCES

SEE ALSO
- Addison Disease: Hypokalemia
CLINICAL PEARLS

- Emergency and urgent management of hyperkalemia takes precedence to a thorough diagnostic workup. Urgent treatment includes stabilization of the myocardium with calcium gluconate to protect against arrhythmias and pharmacologic strategies to move K from the extracellular (vascular) space into cells.
- Calcium and dextrose/insulin are only temporizing measures and do not actually lower total body K levels. Definitive treatment with either dialysis or cation exchange resin (sodium polystyrene sulfonate) is necessary.
- To lower a patient’s risk of developing hyperkalemia, have the patient follow a low-K diet, use selective β₁-blockers such as metoprolol or atenolol instead of nonselective β-blockers such as carvedilol, avoid NSAIDs. Concomitant use of kaliuretic loop diuretics may be useful.
HYPERNATREMIA
Sasmit Roy, MD, MBBS  Pang-Yen Fan, MD

BASICS

DESCRIPTION
• Serum sodium (Na) concentration >145 mEq/L (1)
• Usually represents a state of hypertonicity (1, 2)
• Na concentration reflects balance between total body water (TBW) and total body Na. Hypernatremia occurs from deficit of water relative to Na.
• Hypernatremia results from net water loss or, more rarely, from primary Na gain (1).
• May exist with hypo-, hyper-, or euvolemia, although hypovolemia is by far most common type
  – Hypovolemic: occurs with a decrease in TBW and a proportionately smaller decrease in total body Na
  – Euvolemic: no change in TBW with a proportionate increase in total body Na
  – Hypervolemic: increase in TBW and a proportionately greater increase in total body Na
• It has been shown to be an indicator for higher mortality in critically ill patients and patients with chronic kidney disease (CKD) (3)[B].
• Hypernatremia will not develop if thirst mechanism is intact and water is available.

EPIDEMIOLOGY

Incidence
• More common in elderly and young
• Occurs in 1% of hospitalized elderly patients (4)
• Seen in about 9% of ICU patients (4). Gastroenteritis with diarrhea is the most common cause of hypernatremia in infants.
• Women are at an increased risk due to decreased TBW, as compared with men.

ETIOLOGY AND PATHOPHYSIOLOGY

Water loss (total body Na normal). Hypernatremia due to water loss occurs only in patients who can’t access water such as infants, elderly, patients with altered mental status and hypodipsia (5). This is called dehydration and differs from hypovolemia where both salt and water are lost. The following conditions lead to water loss:
  – Insensible loss
    o Burns
    o Hyperventilation
    o Excessive sweating, such as with fever, infants under radiant heaters, and exercise
  – Renal loss
    o Nephrogenic diabetes insipidus (DI) (congenital or due to renal dysfunction, hypercalcemia, hypokalemia, medication-related, e.g., lithium)
    o Central DI (due to head trauma, stroke, meningitis) (4)
    o Osmotic diuresis: glucose, urea, and mannitol
    o Post-ATN diuresis
  – Gastrointestinal loss
- Osmotic diarrhea: lactulose, malabsorption, and some types of infectious diarrhea
- Enterocutaneous fistula
- Vomiting, NG suction
  - Hypothalamic disorders leading to impaired thirst or osmoreceptor function
  - Primary hypodipsia
  - Reset osmostat due to volume expansion in mineralocorticoid excess.
- Essential hypernatremia with loss of osmoreceptor function

- Excess Na (increase in total body Na) resulting from the following:
  - IV NaCl or NaHCO3 during cardiopulmonary resuscitation, metabolic acidosis, or hyperkalemia (4)
  - Sea water ingestion
  - Excessive use of NaHCO3 antacid
  - Incorrect infant formula preparation
  - Intrauterine NaCl for abortion
  - Excessive Na in dialysate solutions
  - Disorders of the adrenal axis (Cushing syndrome, Conn syndrome, congenital adrenal hyperplasia)
  - Tube feeding

- With acute hypernatremia, the rapid decrease in brain volume can cause rupture of the cerebral veins, leading to focal intracerebral and subarachnoid hemorrhages and possibly irreversible neurologic damage (2).

**Genetics**
Some forms of DI may be hereditary.

**RISK FACTORS**
- Patients at increased risk include those with an impaired thirst mechanism or restricted access to water as well as those with increased water loss
- Infants/children
- Elderly patients (may also have a diminished thirst response to osmotic stimulation via an unknown mechanism)
- Patients who are intubated/have altered mental status
- Diabetes mellitus
- Prior brain injury
- Surgery
- Diuretic therapy, especially loop diuretics
- Lithium treatment

**GENERAL PREVENTION**
- Treatment/prevention of underlying cause
- Properly prepare infant formula and never add salt to any commercial infant formula.
- Keep patients well hydrated.

**COMMONLY ASSOCIATED CONDITIONS**
- Gastroenteritis
- Altered mental status
- Burns
- Hypermetabolic conditions
Head injury
Renal dysfunction

DIAGNOSIS

HISTORY
- Excessive thirst, nausea, vomiting, diarrhea, oliguria, polyuria
- Fever, myalgia, muscle weakness
- Neurologic symptoms common: altered mental status, seizure (especially if rapid development of hypernatremia), twitching, lethargy, irritability, coma, anophthalmos
- Severe symptoms are likely to occur with acute increases in plasma Na levels or at concentrations >160 mEq/L.
- Obtain list of current and recent medications.
- Review recent illnesses and activities.

PHYSICAL EXAM
- Sinus tachycardia, hypotension, orthostatic hypotension, poor O₂ saturation
- Dry mucous membranes, cool/gray skin
- Neurologic abnormalities: lethargy, weakness, focal deficits (in cases of intracerebral bleeding/lesion), confusion, coma, seizures

DIFFERENTIAL DIAGNOSIS
- DI
- Hyperosmotic coma
- Salt ingestion
- Hypertonic dehydration
- Hypothyroidism
- Cushing syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Serum Na, potassium, BUN, creatinine, calcium, and osmolality (serum lithium if appropriate)
- Urine Na and osmolality
  - DI: urine osmolality (usually <300 mOsmol/kg) < serum osmolality, and urine Na usually low normal/slightly low (due to dilution) (5)
  - Partial DI and central DI with volume depletion can give a urine osmolarity of 300 to 800 mOsm/kg.
  - Osmotic diuresis: urine osmolality intermediate, urine Na low/low-normal, total daily osmole excretion high
  - Salt ingestion: increased urine osmolality (>600 mOsmol/kg) and high urine Na
  - Hypertonic dehydration: increased urine osmolality and decreased urine Na
- Serum glucose
- Special tests for DI
  - Water deprivation test: In DI, urine osmolality does not increase because it normally should when hypernatremic.
  - Antidiuretic hormone (ADH) stimulation: distinguishes central versus nephrogenic DI
Urine osmolality does not increase after ADH or desmopressin in nephrogenic DI.

Head CT/MRI in DI to rule out craniopharyngioma, other brain tumor or masses, or median cleft syndrome

Diagnostic Procedures/Other
History, physical, laboratory studies, family history for central DI

TREATMENT

GENERAL MEASURES

- The treatment of hypernatremia involves treating the underlying cause and correcting the water deficit.
- Goal for corrected Na is 145 mEq/L (1).
- Speed of correction depends on symptom severity and rate of development of hypernatremia. Avoid rapid correction to prevent development of cerebral edema if chronic hypernatremia (>24 hours):
  - Maximum of 0.5 mEq/L/hr or 10 mEq/L/day
  - May correct at up to 1 mEq/L/hr if acute hypernatremia (<24 hours) (1)
- Treat volume depletion first and then hypernatremia:
  - Restore intravascular volume with IV fluids to normalize serum Na levels.
  - Replace water orally if patient is conscious.
- Important formulas in determining rate of fluid administration
  - \( TBW = \text{coefficient} \times \text{wt (kg)}, \) where \( \text{coefficient} = 0.6 \text{ for men and children}, 0.5 \text{ for women and elderly men}, 0.45 \text{ for elderly women} \)
  - Calculated free water deficit (liters) = \( TBW \times (PNa / 140 - 1) \), where \( PNa = \text{plasma Na}^+, \text{TBW = total body water} \)
  - Change in serum Na per 1 L infusate = \( [(\text{infusate Na} + \text{infusate K}) - \text{serum Na}] / (TBW + 1) \)
  - Example: A 45-year-old male weighing 70 kg is admitted with head injury. Labs show a serum Na of 160.
    - Free water deficit = \( 70 \times 0.6 \times (160 / 140 - 1) = 6 \text{ L} \)
    - Remember the 6 L should be given over a 48-hour period to avoid over correction.
- Account for ongoing fluid losses during calculation of rate of fluid administration(i.e., insensible water loss through skin and water lost through urine, stool).
- Dialysis can be considered if acute kidney injury is present concomitantly and if conventional treatment has failed (6)[B].

MEDICATION

First Line

- See “General Measures” for overall approach.
- Volume depletion: Use isotonic fluids initially if signs of hemodynamic compromise and then change to hypotonic fluids when stable:
  - Hypotonic fluids (0.45% NaCl or dextrose 5% in water)
    - Important not to decrease serum Na by >10 mEq/L/day to prevent cerebral edema (5)[C]
- Hypervolemia: Give furosemide along with hypotonic fluids. Dose varies depending on desired urine output. Loop diuretics with fluid restriction worsen hypernatremia (5)[C].
Central DI
- Desmopressin acetate (DDAVP): Use parenteral form for acute symptomatic patients, and use intranasal or oral form for chronic therapy (5).
- Free water replacement: may use 2.5% dextrose in water if giving large volumes of water in DI to avoid glycosuria
- May consider sulfonylureas/thiazide diuretics for chronic but not acute treatment

Nephrogenic DI
- Treat with diuretics and NSAIDs.
- Lithium-induced nephrogenic DI: hydrochlorothiazide 25 mg PO BID or indomethacin 50 mg PO TID, or amiloride hydrochloride 5 to 10 mg PO BID

Precautions
- Rapid correction of hypernatremia can cause cerebral edema, central pontine myelinolysis, seizures, or death.
- Hypocalcemia and more rarely acidosis can occur during correction.
- DI: High rates of dextrose 5% in water can cause hyperglycemia and glucose-induced diuresis.

Second Line
- Consider NSAIDs in nephrogenic DI.
- Modalities requiring further investigations
- Continuous renal replacement therapy (CRRT): Multiple case reports and case series have shown success and safety in using CRRT to treat hypernatremia in critically ill patients with CHF and severe burns (6).

ISSUES FOR REFERRAL
Underlying renal involvement associated with hypernatremia would benefit from a nephrology referral.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Symptomatic patient with serum Na >155 mEq/L requires IV fluid therapy.
- IV fluids: Refer to “Medication” section.
- Bed rest until stable or underlying condition resolved/controlled
- Discharge criteria: Stabilization of serum Na level and symptoms are minimal.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Frequent reexams in an acute setting
- Frequent electrolytes and blood glucose: initially q4–6h
- Urine osmolality and urine output in DI
- Ensure adequate ingestion of calories because patients may ingest so much water that they feel full and do not eat.
- Measure ongoing losses of water and solute and replace as needed.
- Daily weights
DIET
- Ensure proper nutrition during acute phase.
- After resolution of acute phase, may want to consider Na-restricted diet for patient
- Low-salt, low-protein diet in nephrogenic DI

PATIENT EDUCATION
Patients with nephrogenic DI must avoid salt and drink large amounts of water.

PROGNOSIS
Most recover but neurologic impairment can occur.

COMPLICATIONS
- CNS thrombosis/hemorrhage
- Seizures
- Mental retardation
- Hyperactivity
- Chronic hypernatremia: >2 days duration has higher mortality.
- Serum Na >180 mEq/L (>180 mmol/L): often results in residual CNS damage
- More common if rapid development of hypernatremia

REFERENCES

ADDITIONAL READING

SEE ALSO
- Diabetes Insipidus
- Algorithm: Hypernatremia
ICD10
E87.0 Hyperosmolality and hypernatremia

CLINICAL PEARLS

- Occurs from water deficit in comparison to total body Na stores
- Common causes include dehydration, DI, impaired access to fluids.
- Determine if the patient has hypervolemic, euvolemic, or hypovolemic hypernatremia in the differential diagnosis of etiology; most commonly hypovolemic; other entities rare
- Avoid rapid correction of hypernatremia to prevent development of cerebral edema when hypernatremia is chronic (goal rate is 10 mEq/L in 24 hours).
- Use hypotonic fluids unless patient has hemodynamic compromise, which necessitates use of isotonic fluids.
- Use oral replacement in conscious patients if possible.
- Use the estimated water deficit, desired rate of correction, and estimation of ongoing free water losses to calculate a fluid repletion regimen.
HYPERPARATHYROIDISM
Michael G. Morkos, MD, MS • Sonal Vaid, MD, BME

BASICS

DESCRIPTION
A dysfunction of the body’s normal regulatory feedback mechanisms resulting in excess production of parathyroid hormone (PTH)

- Primary hyperparathyroidism (HPT): intrinsic parathyroid gland dysfunction resulting in excessive secretion of PTH with a lack of response to feedback inhibition by elevated calcium
- Secondary HPT: excessive secretion of PTH in response to potential hypocalcemia and/or hyperphosphatemia. This can be caused by vitamin D deficiency, kidney dysfunction, decreased calcium intake, and/or phosphate loading.
- Tertiary HPT: autonomous hyperfunction of the parathyroid gland in the setting of longstanding secondary HPT

EPIDEMIOLOGY
Incidence
- Predominantly postmenopausal females
- Female > male (3:1)

Prevalence
Primary HPT is 1 in 500 to 1 in 1,000 in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY
- PTH is synthesized by the four parathyroid glands, which are located behind the four poles of the thyroid gland (locations can vary).
- Ectopic (abnormal locations and most common is the thymus) or supernumerary glands (more than four glands)
- PTH releases calcium from bone by osteoclastic stimulation (increasing bone resorption).
- PTH increases reabsorption of calcium in the distal tubules of the kidneys.
- PTH stimulates conversion of 25-hydroxycholecalciferol (25[OH]D) to 1,25-dihydroxycholecalciferol (1,25[OH]_2D or active vitamin D) in the kidneys. 1,25(OH)_2D increases calcium and phosphate absorption from the gastrointestinal tract and kidneys, and stimulates osteoclastic activity and bone resorption.
- Primary HPT: unregulated PTH production and release due to the loss of normal feedback control by extracellular calcium, causing increase in serum calcium
  - Solitary adenoma (80–85%)
  - Diffuse hyperplasia (10–15%) of the four parathyroid glands, either sporadically or in association with multiple endocrine neoplasia (MEN) types I or II
  - Parathyroid carcinoma (<1%), a very rare and severe form
- Secondary HPT: adaptive parathyroid gland hyperplasia and hyperfunction
  - Dietary: vitamin D or calcium deficiency
  - Chronic renal disease resulting in the following:
    - Renal parenchymal loss causing hyperphosphatemia
- Impaired calcitriol production causing hypocalcemia
- General skeletal and renal resistance to PTH
- Tertiary HPT: autonomous oversecretion of PTH following prolonged parathyroid stimulation

**Genetics**
- MEN types I and II: Patients with multiple gland hyperplasia in the absence of renal disease should be screened for MEN-I gene mutation.
- Neonatal severe primary HPT
- HPT—jaw tumor syndrome
- Familial hypocalciuric hypercalcemia (FHH)
- Familial isolated HPT

**RISK FACTORS**
Chronic kidney disease, increasing age, poor nutrition, radiation, and/or family history

**GENERAL PREVENTION**
Adequate intake of calcium and vitamin D may help prevent secondary HPT.

**COMMONLY ASSOCIATED CONDITIONS**
- Vitamin D deficiency
- Chronic renal failure
- MEN syndromes types I and II

**DIAGNOSIS**

**HISTORY**
- History of present illness
  - Almost 80% of patients are asymptomatic.
  - Kidney stones (15–20%)
  - Osteitis fibrosa cystica (<5%) characterized by subperiosteal resorption of phalanges, tapering of distal clavicles, bone cysts, brown tumors of long bones, and "salt and pepper" appearance of the skull
  - Symptoms due to hypercalcemia like mental fogginess, memory impairment, polyuria, polydipsia, constipation, bone pain, decreased concentration, fatigue, and muscle weakness
- Past medical history
  - The following conditions may be associated with HPT:
    - MEN syndrome (MEN-associated conditions include pancreatic cancer, pituitary adenomas, medullary thyroid cancer, and pheochromocytoma), nephrolithiasis (in 20–30%), nephrocalcinosis, pancreatitis, gastroduodenal ulcer, hypertension, short QT interval, left ventricular hypertrophy, osteitis fibrosa cystica, cystic bone lesions, spontaneous fracture, vertebral collapse, osteoporosis, gout, pseudogout, anxiety, depression, psychosis, coma, conjunctivitis, band keratopathy, conjunctival calcium deposits, radiation to the neck
  - Medications: hydrochlorothiazide or lithium (decreases parathyroid sensitivity to calcium in small subset of patients)

**PHYSICAL EXAM**
• Limited usefulness; 70–80% of patients have no obvious symptoms or signs of disease.
• Physical findings related to the underlying cause of HPT may be found.

DIFFERENTIAL DIAGNOSIS
• Increased PTH: Ectopic PTH production is rare. In most of the cases, it establishes the diagnosis of primary HPT, but first rule out:
  – FHH
  – Thiazide diuretics and lithium
• Nonparathyroid causes
  – Malignancy: lung (squamous cell) carcinoma, breast carcinoma, multiple myeloma, lymphoma, leukemia, prostate cancer, Paget disease
  – Granulomatous diseases: sarcoidosis, tuberculosis, berylliosis, histoplasmosis, coccidioidomycosis
  – Drugs: vitamin D intoxication, milk-alkali syndrome
  – Endocrine: hyperthyroidism, acute adrenal insufficiency

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Often detected by incidental hypercalcemia on routine labs. The best modality is to check ionized calcium.
• Calculate corrected calcium: \[
  \text{Corrected calcium} = \frac{\text{Serum calcium (mg/dL)}}{\frac{\text{4} - \text{Patient's albumin (g/dL)}}{0.8}}
\]
  Some patients will have mild hypercalcemia for years, and it won’t be detected as the uncorrected calcium is normal.
• If hypercalcemia is confirmed, follow with intact PTH level (1)
  – PTH-dependent: High or (abnormally) normal PTH suggests primary HPT.
  – PTH-independent: Undetectable or low PTH suggests PTH-independent hypercalcemia.
• Other findings may include low serum phosphate and high 24-hour urine calcium excretion.
• In secondary HPT, an elevated phosphorus suggests chronic renal failure; a low phosphorus suggests another cause, commonly 25(OH)D deficiency. Both are common causes of elevated PTH levels while having normal corrected calcium levels.

Follow-Up Tests & Special Considerations
• A 24-hour urine calcium concentration to creatinine clearance ratio >0.02 suggests primary HPT; a ratio <0.01 may be normal or indicate FHH; an important finding because FHH does not require surgery (1).
• Routine measurement of 25(OH)D levels is recommended in all patients with primary HPT. In case of vitamin D deficiency (<20 ng/mL or <50 nmol/L), defer management decisions until levels are maintained >20 ng/mL (50 nmol/L) (1).

Diagnostic Procedures/Other
• Imaging is not required for diagnosis. It is required for surgical planning, especially for minimally invasive parathyroidectomy (MIP) (2).
  – Imaging is also indicated to localize hyperplasia or an ectopic parathyroid gland in repeat surgery.
• Imaging options for presurgical localization
  – Technetium-99m sestamibi with or without single-photon emission computed tomography (SPECT): it has the greatest reported success in localizing single parathyroid adenomas but
often inaccurate in multigland disease (3)[B].
– Neck ultrasound (US): painless, noninvasive, and does not expose the patient to radiation; however, its accuracy is operator-dependent (4)[C].
– Four-dimensional CT (4D-CT) may be more effective for primary localization than both US and sestamibi-SPECT (4)[B].
– Positron emission tomography (PET) using C-methionine (MET-PET) is comparable to US and technetium-99m sestamibi with SPECT in terms of diagnostic use (2)[B].
– CT and MRI are mostly used to localize ectopic mediastinal glands.

TREATMENT

MEDICATION

● Primary HPT: Operative management is curative; indications for surgical intervention are mentioned below. For those awaiting or unable to have surgery:
  – Bisphosphonates (alendronate): reduce bone turnover and help to maintain bone density; avoid in kidney disease (GFR ≤35).
  – Calcimimetics (cinacalcet) (1)[B]: activates calcium-sensing receptor in parathyroid gland thereby inhibiting PTH secretion. FDA-approved for symptomatic patients who are unfit for surgery; no long-term data on its effect on constitutional, neuropsychological symptoms or fractures
  – Selective estrogen receptor modulator therapy (raloxifene): antagonizes PTH-mediated bone resorption
  – Hormone replacement therapy with estrogens is not recommended as first-line treatment; must weigh benefit with risks of known systemic effects
    o Can be used in postmenopausal women who do not undergo or refuse surgery
● Secondary HPT
  – Calcium replacement
  – Vitamin D analogues (paricalcitol and calcitriol)
  – Phosphorus-binding agents (sevelamer)
  – Calcimimetic (cinacalcet)
● Tertiary HPT
  – Medical treatment is not curative and generally not indicated.

SURGERY/OTHER PROCEDURES

● Operative management is curative for patients with primary HPT in 95–98% of patients.
● Indications for parathyroidectomy
  – Symptomatic primary HPT
    o Nephrolithiasis
    o Fragility fractures
    o Osteitis fibrosa cystica
  – Asymptomatic primary HPT (1)[C]
    o Serum Ca$^+$ level >1 mg/dL above normal
    o Age <50 years
    o Creatinine clearance <60 mL/min
    o 24-hour urine for calcium >400 mg/day (>10 mmol/day) and increased stone risk by biochemical stone risk analysis
Presence of nephrolithiasis or nephrocalcinosis by x-ray, US, or CT
Bone density loss with a T-score $<-2.5$ at the lumbar spine, femoral neck, total hip, or distal 1/3 radius

Tertiary HPT
Surgical removal of diseased gland or tissue is only proven curative therapy for HPT.
Surgical options include the following:
- Bilateral open neck exploratory surgery
- MIP using preoperative sestamibi scan with SPECT/US/4D-CT and intraoperative PTH levels (high sensitivity 79–95% to predict location of single parathyroid adenoma) (5), which result in decreased pain, smaller incisions, improved cosmetic results, lower morbidity, and decreased length of hospital stay when compared with open neck exploratory surgery
Follow postoperative serum calcium, magnesium, and phosphorus levels; monitor closely for hypocalcemia “hungry bone” syndrome.
Patients may need IV calcium infusion postoperatively with oral calcitriol and calcium supplementation initially. Hungry pain syndrome can be severe, although less common now.
Patients also at risk for bleeding and airway compromise
Monitor renal function closely.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Critical hypercalcemia requires IV fluid rehydration, IV bisphosphonate therapy, and SC calcitonin (4 U/kg q12h) for severe symptoms.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Asymptomatic patients with primary HPT require serial monitoring of calcium and PTH.

Patient Monitoring
In patients with primary HPT who are asymptomatic, measurement of serum calcium and creatinine annually and bone density scan every 1 to 2 years is sufficient (1)(C).

DIET
- In the presence of hypercalciuria or elevated 1,25(OH)$_2$D levels, dietary calcium restriction is recommended. Otherwise, daily calcium intake should be maintained at up to 1,000 mg.
- Restrict dietary phosphate in secondary HPT.

PATIENT EDUCATION
- Importance of periodic lab testing
- Signs of severe hypercalcemia

PROGNOSIS
Prognosis after surgery is excellent in primary HPT, with resolution of many of the preoperative symptoms.

COMPLICATIONS
Related to high levels of PTH and/or elevated calcium
REFERENCES

CODES

ICD10
- E21.3 Hyperparathyroidism, unspecified
- E21.0 Primary hyperparathyroidism
- E21.1 Secondary hyperparathyroidism, not elsewhere classified

CLINICAL PEARLS

- 80% of patients with primary HPT are asymptomatic.
- HPT is often detected by an incidental finding of hypercalcemia on a routine serum chemistry analysis.
- Classic symptoms of HPT include painful bones, renal stones, abdominal pain, and behavioral changes (stones, bones, moans, and groans).
- Repeat calcium (elevated), correct for serum albumin, and obtain intact PTH levels to make an initial diagnosis.
- Secondary HPT is due to excessive secretion of PTH in response to hypocalcemia, which can be caused by vitamin D deficiency or renal failure.
- In patients with primary HPT who are asymptomatic, measurement of serum calcium and creatinine annually and bone density scan every 1 to 2 years is sufficient.
HYPERPROLACTINEMIA
D’Ann Somerall, DNP, MAEd, CRNP, FNP-BC • William E. Somerall Jr., MD, MEd

BASICS

DESCRIPTION
Hyperprolactinemia is an abnormal elevation in the serum prolactin level, from either physiologic or pathologic influences of the lactotroph cells of the pituitary gland.

EPIDEMIOLOGY

Prevalence
- Predominant age: reproductive age
- Predominant sex: female > male
- More readily detected in females because a slight elevation in prolactin causes changes in menstruation and galactorrhea

ETIOLOGY AND PATHOPHYSIOLOGY

- Prolactin, which is produced by lactotrophs in the anterior pituitary, is regulated by:
  - Inhibitory factors, primarily dopamine, produced in the hypothalamus and delivered via the hypothalamic-pituitary vessels in the pituitary stalk
  - Stimulatory factors, primarily thyrotropin-releasing hormone (TRH)
- Causes of hyperprolactinemia include the following:
  - Physiologic
  - Pregnancy due to increased estrogen
  - Breastfeeding
  - Nipple stimulation
  - Stress, including postoperative state
  - Medications-concentrations are typically in the 25–100 ng/mL range (1)[A]
    - Dopamine (D₂) blockers: prochlorperazine, metoclopramide
    - Dopamine depleters: α-methyldopa, reserpine
    - Antidepressants: selective serotonin reuptake inhibitors (SSRIs), tricyclic antidepressants (SSRIs do not appear to cause clinically significant hyperprolactinemia.)
    - Verapamil (but no other calcium channel blockers; thought to decrease hypothalamic synthesis of dopamine)
    - Antipsychotics: (category is the most common cause of medication induced) haloperidol, fluphenazine, risperidone
  - Hypothyroidism (due to elevated TRH)
  - Chest wall conditions:
    - Herpes zoster
    - After thoracotomy
    - Trauma
  - Prolactin-secreting adenoma (anterior pituitary), categorized:
    - Microadenoma: <1 cm
    - Macroadenoma: >1 cm
– Pituitary stalk compression/disruption:
  o Craniopharyngioma
  o Rathke cleft cyst
  o Meningioma
  o Astrocytoma
  o Metastases
  o Head trauma
  o Infiltrative/inflammatory disorders
– Diminished prolactin clearance:
  o Chronic renal failure
  o Cirrhosis
  – Cocaine
  – Idiopathic hyperprolactinemia—when the serum levels are between 20–100 ng/mL but etiology cannot be found (2)[A]

DIAGNOSIS

HISTORY

- Galactorrhea
- Amenorrhea
- Oligomenorrhea
- Infertility
- Osteoporosis/osteopenia
- Decreased libido, impotence
- Weight gain
- Also may have signs and symptoms of pituitary enlargement:
  - Headache
  - Visual field impairment (bitemporal hemianopia)
  - Hypopituitarism (secondary to tumor pressure on surrounding structures)
- Also may have signs and symptoms of associated conditions:
  - Hypothyroidism
  - Cushing disease
  - Acromegaly
  - Multiple endocrine neoplasia (MEN)-1 syndrome

PHYSICAL EXAM

- Visual field testing
- Cranial nerve exam

DIFFERENTIAL DIAGNOSIS

Macroprolactinemia: Macroprolactin, a polymer of several units of prolactin, is detected by immunologically based lab tests but is not biologically active. If patient is asymptomatic but found to have elevated prolactin (PRL), consider this diagnosis and notify the lab. No treatment is required.

DIAGNOSTIC TESTS & INTERPRETATION

- Serum prolactin (most accurate results if checked fasting, in morning; food only has a small
effect on concentrations, thus fasting is not required, but if elevated levels repeat on a fasting specimen) <25 μg/L normal; >25 μg/L abnormal; >30 in postmenopausal women; >250 μg/L often indicates a prolactinoma (3)[A].

- Pregnancy test
- Thyroid-stimulating hormone (TSH)
- Luteinizing hormone (LH)/follicle-stimulating hormone (FSH) if amenorrheic
- Chemistry, renal function
- Liver function tests

**Initial Tests (lab, imaging)**
A single measurement of serum prolactin; a level above the upper limit of normal confirms the diagnosis.
- Pituitary MRI: single best imaging
- CT scan if MRI is contraindicated
- Levels should be drawn prior to breast exam.

**Follow-Up Tests & Special Considerations**
Formal visual field testing if pituitary adenoma is suspected

**TREATMENT**

**GENERAL MEASURES**
- Discontinue offending medications, if any (3)[A].
- Treat underlying causes (3)[A].
- For asymptomatic patients with mild prolactin elevations, observation alone may be considered (3)[A],(4)[A].
- Medications indicated for (3)[A]:
  - Symptoms of hypogonadism, such as decreased libido
  - Galactorrhea (if bothersome to patient)
  - Restoration of fertility
  - Pituitary adenoma
  - Prevention of osteoporosis

**MEDICATION**
Dopamine agonists: decrease serum prolactin concentrations and decrease the size of most lactotroph adenomas
- Cabergoline (Dostinex): This is now a first-line choice due to efficacy and favorable side effect profile (3)[A],(5)[A]: dosed 0.25 mg twice weekly or 0.50 once a week. Cabergoline was more effective than bromocriptine in reducing persistent hyperprolactinemia, galactorrhea, and amenorrhea/oligomenorrhea (4)[A]. Has recently been reported to be associated with significant improvements in the body mass index, total high-density lipoprotein and low-density lipoprotein cholesterol levels, and insulin sensitivity (6); decrease in proinflammatory markers; and carotid intima-media thickness, indicated with bromocriptine failure or resistance; has been shown to reduce erectile dysfunction in hyperprolactinemic men (3)[A]
  - Adverse effects (better tolerated if start with low dose, slow titration, given at night with
---

**ADDITIONAL THERAPIES**

Patients with medically and surgically refractory prolactinomas; radiotherapy produced a reduction in prolactin levels in nearly all patients and normalization in over a quarter of patients with low complication rates (4)[A].

**SURGERY/OTHER PROCEDURES**

- For adenomas, medical treatment will be successful in 80–90% of patients. In some cases, surgery is indicated (3).

  - **Indications**
    - Intolerance or resistance to medical treatment
    - Headache
    - Visual field loss
    - Cerebrospinal fluid (CSF) leak due to tumor apoplexy or shrinkage
    - Cranial nerve deficit
  
  - **Risks**
    - High recurrence rate (up to 40%)
    - CSF leakage
    - Meningitis
    - Transient diabetes insipidus (7)

- Pituitary insufficiency

---

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Reevaluate lab levels after 1 month; if normal, continue the initial dose. If lab levels do not decrease, but patient experiences no side effects, increase cabergoline to 1.25 mg 2 to 3 times/week or bromocriptine to 5 mg twice a day.

---

- Nausea/vomiting
- Headache
- Dizziness
- Fatigue
- Light-headedness
- Postural hypotension (4)[A]

**Contraindications**

- Uncontrolled hypertension
- Cardiac valvular disorders
- Pulmonary, pericardial, or retroperitoneal fibrotic disorders

---

**Bromocriptine (Parlodel):** This has the longest clinical history: dosed BID; begin at 1.25 mg once at bedtime or after dinner for 1 week then increase to BID; preferred by some clinicians when infertility is an indication for treatment (1)[A],(4)[A].

- Both are effective at reducing tumor size and improving symptoms (4)[A].
- SE less with cabergoline than bromocriptine (4)[A]. Pergolide (Permax) is no longer used in the United States. If patient is still on med, do not withdraw abruptly.
**Patient Monitoring**
- Depends on etiology
- After at least 2 years of treatment, no tumor and prolactin levels normal may consider decreasing and stopping medication; must be followed closely, as tumor may grow back (3)
- Consider:
  - Formal visual field testing yearly (1)[A]
  - Serial MRIs if clinically indicated (1)[A]

**Pregnancy Considerations**
- If pregnancy is desired in a woman with hyperprolactinemia, dopamine agonists are not approved during pregnancy and should be discontinued once pregnancy is confirmed, but their use is recommended if neurologic findings are present (3)[A].
- With microprolactinoma: Treat with bromocriptine if symptomatic; monthly pregnancy tests; discontinue bromocriptine when pregnancy is confirmed.
- With macroprolactinomas: a definitive, individualized plan is made. Options include discontinuation of bromocriptine at conception and careful monitoring of prolactin levels and VS, with or without MRI scan evidence of tumor enlargement; prepregnancy transsphenoidal surgery with debulking of tumor; continuation of bromocriptine throughout gestation, with a risk to the fetus.
- Careful monitoring of visual fields in each trimester; no need to monitor prolactin levels, as they are normally high due to pregnancy (3)[A]

**PATIENT EDUCATION**
- Discuss risks of untreated hyperprolactinemia:
  - Headache
  - Visual field loss
  - Decreased bone density
  - Infertility
- Patient guide to hyperprolactinemia diagnosis and treatment

**PROGNOSIS**
- Tends to recur after discontinuation of medical therapy (3)
- >10 years, 7% chance of progression of prolactin-secreting microadenoma (1)

**COMPLICATIONS**
- Depends on underlying cause
- If pituitary adenoma, risk of permanent visual field loss
- For patients with high doses of cabergoline suggest cardiac U/S every 2 years

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

E22.1 Hyperprolactinemia

**CLINICAL PEARLS**

- If a cause for hyperprolactinemia cannot be found by history, examination, and routine laboratory testing, an intracranial lesion might be the cause and brain MRI with specific pituitary cuts and intravenous contrast media should be performed.
- Treatment of hyperprolactinemia should be targeted at correcting the cause (hypothyroidism, discontinuation of offending medications, etc.).
- There is a difference among antipsychotics in influencing prolactin levels. In general, those with the highest potency D2 antagonism are most likely to elevate prolactin levels. Among the newer atypical antipsychotics, risperidone has been identified as more likely to elevate prolactin.
- High prolactin levels decrease testosterone by inhibiting gonadotropin-releasing hormone (GnRH), LH, and FSH secretion and by decreasing central dopamine activity, both of which are important in mediating sexual arousal.
HYPERSENSITIVITY PNEUMONITIS
Han Q. Bui, MD

BASICS

DESCRIPTION

- Hypersensitivity pneumonitis (HP) is also called extrinsic allergic alveolitis (EAA).
- HP is a diffuse inflammatory disease of the lung parenchyma caused by an immunologic reaction to aerosolized antigenic particles found in a variety of environments. Classification depends on time frame involved:
  - Acute: fever, chills, diaphoresis, myalgias, nausea; cough and dyspnea common but not necessarily present. Occurs 4 to 12 hours after heavy exposure to an inciting agent. Symptoms subside within 12 hours to several days after removal from exposure. Complete resolution occurs within weeks.
  - Subacute: mainly caused by continual low-level antigen exposure, could have a low-grade fever in 1st week; cough, dyspnea, fatigue, anorexia, weight loss—develops over days to weeks
  - Chronic: from recurrent exposure either acute or subacute cases; prolonged and progressive cough, dyspnea, fatigue, weight loss; could lead to fibrosis and respiratory failure
- Farmer’s lung is an old term of this disease, a type of HP, particular to the farmer population; causative agent is a bacterium found in moldy hay or straw. Farmer’s lung now has new and different etiologies due to modernization of farming practices (1,2).

EPIDEMIOLOGY

- Not well-defined; tends to occur in adults as a result of occupation-related exposure, but some home environmental exposures are also seen
- HP is increasingly recognized as an important cause of fibrotic interstitial lung disease (3).

Incidence
0.9/100,000

Prevalence

- Farmers: 1–19% exposed farmers
- Bird fanciers: 6–20% exposed individuals
- Others: 1–8% exposed

ETIOLOGY AND PATHOPHYSIOLOGY

- Hypersensitivity reaction involving immune complexes: Inhaled antigens bind to IgG, triggering complement cascade (types III and IV immunologic reactions) (3).
- Cellular-mediated reaction: T-cell–mediated immune inflammatory response
- Farming, vegetable, or dairy cattle workers (1,2)
  - Moldy hay, grain, silage: thermophilic actinomycetes, such as Faenia rectivirgula
  - Mold on pressed sugar cane: Thermoactinomycetes sacchari, Thymus vulgaris
  - Tobacco plants: Aspergillus sp., Scopulariopsis brevicaulis
  - Mushroom worker’s lung: Saccharopolyspora rectivirgula, T. vulgaris, Aspergillus spp.
  - Potato riddler’s lung: thermophilic actinomycetes, T. vulgaris, F. rectivirgula, Aspergillus
Wine maker’s lung: *Mucor stolonifer*
Cheese washer’s lung: *Penicillium caseifulvum, Aspergillus clavatus*
Coffee worker’s lung: coffee bean dust
Tea grower’s lung: tea plants

**Ventilation and water-related contamination** (1,2)
- Contaminated humidifiers and air conditioners: amoebae, nematodes, yeasts, bacteria
- Unventilated shower: *Epicoccum nigrum*
- Hot-tub lung: *Cladosporium sp., Mycobacterium avium complex*
- Sauna taker’s lung: *Aureobasidium sp.*
- Summer-type pneumonitis: *Trichosporon cutaneum*
- Swimming pool lifeguard’s lung: aerosolized endotoxin and *M. avium complex*
- Contaminated basement pneumonitis: *Cephalosporium* and *Penicillium spp.*

**Bird and poultry handling** (1)
- Bird fancier’s lung: droppings, feathers, serum proteins
- Poultry worker’s lung: serum proteins
- Turkey-handling disease: serum proteins
- Canary fancier’s lung: serum proteins
- Duck fever: feathers, serum proteins

**Veterinary work and animal handling** (1,2)
- Laboratory worker’s lung: urine, serum, pelts, proteins
- Pituitary snuff taker’s disease: dried, powdered neurohypophysis
- Furrier’s lung: animal pelts
- Bat lung: bat serum protein
- Fish meal worker’s lung: fish meal
- Coptic lung: cloth wrapping of mummies
- Mollusc shell HP: sea-snail shell
- Pearl oyster shell pneumonitis: oyster shells

**Grain and flour** (1,2)
- Grain measurer’s lung: cereal grain, grain dust
- Miller’s lung: *Sitophilus granarius*
- Malt worker’s disease: *Aspergillus fumigatus, A. clavatus*

**Lumber milling, construction, wood stripping, paper, wallboard manufacture** (1,2)
- Wood dust pneumonitis: *Alternaria sp., Bacillus subtilis*
- Sequoiosis: *Graphium, Pulilarma, Trichoderma sp., Aureobasidium pullulans*
- Maple bark disease: *Cryptostruma corticale*
- Wood trimmer’s disease: *Rhizopus sp., Mucor sp.*
- Wood pulp worker’s disease: *Penicillium sp.*
- Suberosis: *Trogon viridis, Penicillium glabrum*

**Plastic manufacturing, painting, electronics, chemicals** (1)
- Chemical HP: diphenyl diisocyanate, toluene diisocyanate
- Detergent worker’s lung: *B. subtilis* enzymes
- Pauli reagent alveolitis: sodium diazobenzene sulfate
- Vineyard sprayer’s lung: copper sulfate
- Pyrethrum: *Pyrethrum*
- Epoxy resin lung: phthalic anhydride
RISK FACTORS

- Contact with organic antigens increases the risk of developing HP. Viral infection at time of exposure could also increase risk.
- Nonsmokers have an increased incidence of HP compared with smokers. The mechanisms that account for the “protective” effect of smoking are poorly understood, but nicotine is thought to inhibit macrophage activation and lymphocyte proliferation and function (3).
  - Smokers have a diminished antibody response to inhaled antigens.
  - However, smokers who develop disease tend to have the chronic form, and mortality is higher.

GENERAL PREVENTION

Avoidance of offending antigen and/or use of protective equipment

COMMONLY ASSOCIATED CONDITIONS

Constrictive bronchiolitis

DIAGNOSIS

- Diagnosis criteria most widely used but not validated: (i) history and physical and pulmonary function tests (PFTs) indicating restriction or diffusion disease, (ii) radiologic imaging consent with interstitial lung disease, (iii) exposure to a recognized cause, (iv) proof of sensitization in bronchoalveolar lavage (BAL) fluids (serum precipitins and/or lymphocytosis) (2)
- Six significant predictors: exposure to a known antigen, positive antibodies precipitating, (if identified) recurrent episodes of symptoms, inspiratory crackles, symptoms 4 to 8 hours after exposure, weight loss (3)
- Acute form: develops 4 to 12 hours following exposure. Cough, dyspnea without wheezing, fever, chills, diaphoresis, headache, nausea, malaise, chest tightness. Symptoms last hours to days.
- Sequela (prior subacute, chronic): gradual or progressive productive cough, dyspnea, fatigue, anorexia, weight loss can lead to respiratory failure; develops over days, weeks to months
- Symptomatic improvement when away from work or home

PHYSICAL EXAM

- Acute: fever, tachypnea, diffuse fine rales
- Sequela or chronic: inspiratory crackles, progressive hypoxia, weight loss, diffuse rales,
clubbing, rarely wheezing

DIFFERENTIAL DIAGNOSIS
- Acute: acute infectious pneumonia: influenza (or other viral pneumonia), mycoplasma, Pneumocystis jiroveci pneumonia, asthma, aspiration
- Chronic: sarcoidosis, chronic bronchitis, chronic obstructive pulmonary disease, tuberculosis, collagen vascular disease, idiopathic pulmonary fibrosis, lymphoma, fungal infections, P. jiroveci pneumonia

DIAGNOSTIC TESTS & INTERPRETATION
- Testing for positive precipitating antibodies is NOT diagnostic because up to 40% may have positive antibody without disease; antigens that cover most cases: pigeon and parakeet sera, dove feather, Aspergillus sp., Penicillium, S. rectivirgula, and Thalassomonas viridans
- PFTs: Typical profile is a restrictive pattern with low diffusing capacity; could also have an obstructive pattern (4)
- BAL with serum precipitins and lymphocytosis: usually with low CD4-to-CD8 ratio; findings not unique to HP (1,4)
- Positive antigen–specific inhalation challenge testing: reexposure to the environment, inhalation challenge to the suspected antigen in a hospital setting, but it lacks standardization (3)
- Chest x-ray (CXR): used to rule out other diseases
  - Acute: ground-glass infiltrates, nodular or striated patchy opacities, interstitial pattern in a variety of distributions in lung field. Up to 20% could be normal.
  - Sequela/chronic: upper lobe fibrosis, nodular or ground-glass opacities, volume loss, emphysematous changes
- CT scan of chest; patterns not specific to HP:
  - Acute: ground-glass opacities, poorly defined centrilobular nodules, and ground-glass opacities and air trapping on expiratory images (3,5)
  - Chronic: fibrosis, ground-glass attenuation, irregular opacities, bronchiectasis, loss of lung volume, honeycombing, emphysematous changes (3,5)
- High-resolution CT (HRCT) mid-to-upper zone predominance of centrilobular ground glass or nodular opacities with signs of air trapping (3)
- Usually start with CXR; may progress to HRCT based on findings (3)

Diagnostic Procedures/Other
Lung biopsy:
- Transbronchial: reveals small, poorly formed noncaseating granulomas near respiratory or terminal bronchioles, large foam cells, peribronchial fibrosis
- Open lung biopsy: highest yield in advanced disease; reveals varying patterns of organizing pneumonia, centrilobular and perilobular fibrosis, multinucleated giant cells with clefts

ALERT
HP in farmers must be distinguished from febrile, toxic reactions to inhaled dusts (organic dust toxic syndrome [ODTS]). Nonimmunologic reactions occur 30–50% more commonly than HP in farmers. ODTS is associated with intense exposure occurring on a single day.
TREATMENT

GENERAL MEASURES
Outpatient, except for acute pneumonitis cases and admission for workup (BAL, lung biopsy)

MEDICATION

First Line
- Avoidance of offending antigen is primary therapy and results in disease regression (3).
- Corticosteroids: help control the symptoms of exacerbations but do not improve long-term outcomes
  - Prednisone: 20 to 50 mg daily (3,4)
  - For severe symptomatic patients, initial course of 1 to 2 weeks with taper (3,4)[C]

Second Line
- Bronchodilators and inhaled corticosteroids may symptomatically improve patients with wheeze and chest tightness (4)[C].
- Oxygen may be needed in advanced cases.
- Lung transplantation may be the last resort in severe cases unresponsive to therapy.

ISSUES FOR REFERRAL
Referral to pulmonologist/immunologist

ADMISSION, IN PATIENT, AND NURSING CONSIDERATIONS
Supportive management, as needed, to maintain oxygenation and ventilation:
- Unstable ventilation, oxygen requirement, mental status changes
- Need for invasive evaluation (lung biopsy)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Initial follow-up should be weekly to monthly, depending on severity and course.
- Follow treatments with serial CXR, PFTs, and circulating antibody levels.

DIET
No dietary restrictions

PATIENT EDUCATION
Note that chronic exposure may lead to a loss of acute symptoms with exposure (i.e., the patient may lose awareness of exposure–symptom relationship).

PROGNOSIS
- Presence of fibrosis is a poor prognosis factor (3).
- Acute: good prognosis with reversal of pathologic findings if elimination of offending antigen early in disease (2)
- Sequela/chronic: Corticosteroids have been found to improve lung function acutely but offer
no significant difference in long-term outcome (3)[C].

COMPlications
- Progressive interstitial fibrosis with eventual respiratory failure
- Cor pulmonale and right-sided heart failure

REFERENCES

CODES

ICD10
- J67.9 Hypersensitivity pneumonitis due to unspecified organic dust
- J67.0 Farmer’s lung
- J67.2 Bird fancier’s lung

ClINICAL PEARLS
- Skin testing is not useful for the diagnosis of HP.
- Diagnosis should be suspected in every patient with unexplained cough and dyspnea on exertion, functional impairment (restriction or diffusion defect), and unclear fever, especially if exposure to potential antigens is known (workplace, domestic bird keeping, moldy walls in the home) (2).
- HP may mimic viral upper respiratory illness or asthma exacerbation. Misdiagnosis has critical therapeutic and prognostic implications because it may delay proper treatment, result in significant morbidity, unnecessary hospitalizations, and irreversible fibrosis to the lungs (3).
- Once the disease is established, smoking does not appear to attenuate its severity, and it may predispose to more chronic and severe course.
- Use of protective gear on individual with high-risk exposure occupations can prevent HP.
- Chronic HP is increasingly recognized as an important mimic of other fibrotic lung diseases (3).
HYPERSPLENISM
Shadi Hamdeh, MD ● Adil Abdalla, MD

BASICS
DESCRIPTION

● Hypersplenism is defined as overactivity of the spleen and presents as the following:
  – Splenomegaly (commonly but not always)
  – Cytopenias with respective bone marrow hyperplasia of precursors
  – Resolution of cytopenias with splenectomy

● Splenomegaly is not synonymous with hypersplenism. Overactivity of the spleen can occur
  without enlargement, as is seen in immune thrombocytopenic purpura (ITP) and autoimmune
  hemolytic anemia. Similarly, splenomegaly is not always associated with hypersplenism.

EPIDEMIOLOGY
May be as common as 30–70% in patients with cirrhosis and portal hypertension (HTN)

ETIOLOGY AND PATHOPHYSIOLOGY

● Enlargement of the spleen results in sequestration of formed blood elements, leading to
  peripheral cytopenias and concomitant bone marrow precursor hyperplasia.

● Many of the common etiologies are listed below. Almost any process involving the spleen or
  the hematologic system can result in hypersplenism:
  – Infectious
    o Tuberculosis
    o Brucellosis
    o Malaria
    o Leishmaniasis
    o Ehrlichiosis
    o Schistosomiasis
    o Histoplasmosis
    o Candidiasis
    o Viral
    o Syphilis
    o Infective endocarditis
  – Hematologic
    o Myeloproliferative disorders
    o Polycythemia vera
    o Primary hypersplenism
    o ITP
    o Hemolytic anemias
  – Neoplastic
    o Hematologic malignancies
    o Melanoma
    o Various carcinomas
    o Metastatic cancers
– Storage diseases
  o Gaucher disease
  o Niemann-Pick disease
  o Amyloidosis
  o Glycogen storage disease
– Inflammatory
  o Sarcoidosis
  o Systemic lupus erythematosus
  o Felty syndrome
– Congestive
  o Cirrhosis
  o Heart failure
  o Portal or splenic vein thrombosis
  o Congenital malformations of the portal vein

**DIAGNOSIS**

**HISTORY**
- Patients may complain of abdominal fullness or protrusion of the spleen through the abdominal wall; may complain of early satiety if the spleen is compressing stomach
- Patients may complain of tenderness in the left upper quadrant, especially with viral infections. In lymphoproliferative disorders, spleen may be enlarged but asymptomatic unless there is splenic infarction. Given location of the spleen next to the diaphragm, a sense of fullness may be referred through the phrenic nerve to the C3–C5 dermatomes in the left shoulder.
- Symptoms related to the underlying cause of hypersplenism may be present.

**PHYSICAL EXAM**

Splenomegaly
- The normal spleen is not palpable. A palpable spleen always indicates underlying abnormality such as splenomegaly and, in turn, hypersplenism in the appropriate clinical context or may indicate a wandering spleen. Also, spleen can be palpated in chronic obstructive pulmonary disease and acute asthma exacerbation, without coexisting splenomegaly.
- Begin by percussing Traube semilunar space, demarcated laterally by left anterior axillary line, inferiorly by the left costal margin, and superiorly by the left 6th rib. This space is usually hollow. Splenic enlargement may cause dullness to percussion in this area. Other processes that may cause dullness include pleural or pericardial effusions. Additionally, if the patient recently ate a large meal, this area may be dull to percussion.
- With patient supine, rest hand gently on the abdomen to prevent sudden tensing of the abdominal musculature, which may obscure palpation. Better abdominal relaxation can be obtained by flexing the knees toward the abdomen. As the spleen enlarges, it moves caudally and medially. Start by palpating in the right lower quadrant and moving toward the umbilicus, toward the left upper quadrant. If there is doubt about whether the spleen has moved beyond the costal margin, ask patient to take a large breath, which will push the diaphragm, and, in turn, the spleen toward the examiner’s hands.
- Jaundice: if hemolytic anemia is present or in advanced cirrhosis
- Petechiae, purpura, or ecchymosis: if thrombocytopenia is present
Lymphadenopathy: in hematologic or solid organ malignancies. It also can be seen in infectious etiologies.

**DIAGNOSTIC TESTS & INTERPRETATION**
On CBC, any and all cell lines may be decreased, resulting in the following:
- Anemia
- Leukopenia
- Thrombocytopenia

**Initial Tests (lab, imaging)**
- CBC
- Reticulocyte count if anemia
- If there is hemolysis, there should be an elevated reticulocyte count, elevated LDH, decreased haptoglobin, along with evidence of hyperbilirubinemia (unconjugated).
- US
- CT
- Tc-99m sulfur colloid scintigraphy
- PET
- MRI

**Follow-Up Tests & Special Considerations**
Based on other historical and exam findings, testing for specific infectious etiologies may be warranted:
- Blood parasite smear for malaria and other parasitic infections
- EBV serologies
- HIV ELISA with Western blot
- JAK2 mutation in polycythemia vera
- PPD for tuberculosis
- Hgb electrophoresis in hereditary hemoglobinopathies

**Diagnostic Procedures/Other**
- Bone marrow biopsy
- Liver biopsy for cirrhosis and storage diseases

**Test Interpretation**
Hyperplasia of bone marrow precursors, especially those correlating with the patient’s individual cytopenias

**TREATMENT**

**MEDICATION**
- No specific medication can be recommended for patients with hypersplenism. The most important intervention is to treat the underlying disorder.
- If ITP is the cause, the patient may benefit from the following:
  - Prednisone or methylprednisolone
  - IVIG
  - Rituximab
If an infectious cause is discovered, treatment with appropriate antibiotic therapy may help to improve the cytopenias.

**SURGERY/OTHER PROCEDURES**

- Many patients with severe uncontrolled cytopenias undergo splenectomy.
- Laparoscopic splenectomy is preferred over open splenectomy (1)[A].

**ALERT**

Splenectomized patients should receive immunization to pneumococcus, meningococcus, Haemophilus influenzae, and influenza at least 14 days prior to splenectomy (2)[A].

- If this cannot be done (i.e., in cases of emergent splenectomy), wait at least 14 days postsplenectomy to immunize.
  - Pneumococcal vaccine
    - Pneumococcal polyvalent-23 vaccine (PPSV23) for use in adults and fully immunized children ≥2 years of age
    - Pneumococcal polyvalent-13 vaccine (PCV13) for infants and young children ≥2 months of age as part of routine immunization schedule (3)[A]
      - PCV13 for children ≥2 years of age, adolescents and adults in addition to PPSV23; refer to CDC for timing of administration.
      - Current guidelines recommend single revaccination of PPSV23 5 years after the initial dose and again at age of ≥65 years, at least 5 years after the previous dose.
    - H. influenzae vaccine
      - All unvaccinated individuals ≥5 years of age should be given 1 dose of H. influenzae type B (Hib) conjugate vaccine.
      - Children <5 years old should also be vaccinated. Refer to CDC for timing.
      - Vaccinated individuals can also be given additional dose of vaccine (4)[A].
  - Meningococcal vaccine (5)[A]
    - Meningococcal conjugate vaccine (MCV4) for use in patients between 2 and 55 years
    - Meningococcal polysaccharide vaccine (MPSV4) for use in patients >55 years of age
    - Revaccination is recommended every 5 years.
      - Influenza vaccine should be administered yearly based on prevalent circulating strains. Although patients are not at higher risk from influenza itself, infection with influenza may place patients at higher risk for secondary bacterial infections.
- Radiofrequency ablation (RFA) is becoming more available and can be successful at preventing recurrence of hypersplenism. It is not currently known whether there are differences between RFA and splenectomy in terms of postprocedure infectious risks. Other alternatives to splenectomy include total and partial splenic embolization and shunting, although these techniques are evolving and additional studies are needed to evaluate efficacy and morbidity as compared to splenectomy.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Hypersplenism alone generally does not warrant admission. However, all patients should be monitored closely for complications of the resulting cytopenias, including bleeding and infection, as well as complications of splenomegaly, including increased risk of splenic rupture. In some patients, the large spleen compresses the stomach and prevents adequate oral intake.
- Splenectomized patients are at increased risk of infection and postsplenectomy sepsis,
especially with Streptococcus pneumoniae. Fevers, chills, or pain concerning for underlying infection warrant immediate attention because clinical decompensation can occur within hours. Empiric broad-spectrum antibiotics should not be delayed while evaluation is ongoing. Common empiric regimens include the following:

- Ceftriaxone: 2 g IV q24h and vancomycin 1 g IV q12h
- Levofloxacin: 750 mg IV q24h and vancomycin 1 g IV q12h in β-lactam–allergic patients

**ONGOING CARE**

- Adult patients who are splenectomized should be advised to monitor closely for fever or rigors at home, which may be an early sign of bacteremia. They should be instructed to begin antibiotics immediately prior to proceeding to a medical facility for evaluation. Early antibiotics have been shown to reduce the mortality from overwhelming postsplenectomy sepsis.
- Controlled trials have not been performed, but some regimens include the following:
  - Amoxicillin-clavulanate: 875 mg PO BID
  - Cefuroxime axetil: 500 mg PO BID
- Patients allergic to β-lactam antibiotics can be given an extended-spectrum fluoroquinolone such as levofloxacin 750 mg PO or moxifloxacin 400 mg PO daily.
- In children with splenectomy, daily antibiotic prophylaxis for overwhelming postsplenectomy sepsis with penicillin VK or amoxicillin is recommended until age 5 years or at least 3 years after splenectomy:
  - Age 2 months to 5 years: 125 mg PO BID
  - >5 years old: 250 mg PO BID

**PATIENT EDUCATION**

Patients who are splenectomized should be counseled extensively about the risk of overwhelming postsplenectomy sepsis and the need to obtain prompt medical evaluation in the event of fevers, chills, or any other concerning symptoms.

CODES

ICD10

D73.1 Hypersplenism

CLINICAL PEARLS

- Splenectomy is not necessary to make the diagnosis.
- Avoid splenectomy in patients unless absolutely necessary. Splenectomized patients are at lifelong risk for overwhelming postsplenectomy infection and sepsis.
- If splenectomy is to be performed, give immunization for pneumococcus, meningococcus, H. influenzae, and influenza at least 14 days prior to surgery. Otherwise, wait until the 14th postoperative day to immunize.
HYPERTENSION, ESSENTIAL
Ronald N. Adler, MD, FAAFP • Jeremy Golding, MD, FAAFP

BASICS

DESCRIPTION

• Essential hypertension (HTN) is HTN without an identifiable cause; it is also known as primary HTN and benign HTN. Although its importance as a risk factor for cardiovascular and other morbidity and mortality is well-established, there is significant and increasing controversy regarding recommended thresholds for diagnosis and treatment.

• HTN is defined (Joint National Committee [JNC] 8) as ≥ 2 elevated blood pressures (BPs) (1).
  - Age <60 years: systolic BP (SBP) ≥140 mm Hg and/or diastolic BP (DBP) ≥90 mm Hg at ≥2 visits
  - Age ≥60 years: SBP ≥150 mm Hg and/or DBP ≥90 mm Hg at ≥2 visits
  - With diabetes or chronic kidney disease (CKD): SBP ≥140 and/or DBP ≥90 mm Hg

• Synonym(s): benign, chronic, idiopathic, familial, or genetic HTN; high BP

Geriatric Considerations

• Isolated systolic HTN is common.

• Therapy has been shown to be effective and beneficial at preventing stroke and cardiovascular morbidity and all-cause mortality (2)[A], although target SBP for seniors is higher than in younger patients (~150 mm Hg systolic), and adverse reactions to medications are more frequent. The benefit of therapy has been conclusively demonstrated in older patients for SBP ≥160 mm Hg. A target of <140/90 mm Hg may be appropriate for higher risk individuals (2)[A].

• Very elderly patients may be at particularly high risk of adverse events associated with pharmaceutical treatment of HTN.

• Strongest evidence of benefit has been shown with use of thiazide diuretics

Pediatric Considerations

• Measure BP during routine exams beginning at age 3 years.

• Defined as SBP or DBP ≥95th percentile on repeated measurements

• Pre-HTN: SBP or DBP between 90th and 95th percentile

Pregnancy Considerations

• Elevated BP during pregnancy may represent chronic HTN, pregnancy-induced HTN, or preeclampsia. angiotensin-converting enzyme (ACE) inhibitors and angiotensin II receptor blockers (ARBs) are contraindicated.

• Maternal and fetal mortality are reduced with treatment of severe HTN. Evidence is not clear for treatment of mild HTN (see topic “Preeclampsia and Eclampsia (Toxemia of Pregnancy)”).

• Preferred agents: labetalol, nifedipine, methyldopa, or hydralazine

EPIDEMIOLOGY

Incidence

Incidence and prevalence is higher among men.
Prevalence
Depending on the definition used, 32–46% of adults in the United States have HTN.

ETIOLOGY AND PATHOPHYSIOLOGY
● >90% of cases of HTN have no identified cause.
● For differential diagnosis and causes of secondary HTN, see “Hypertension, Secondary and Resistant.”

Genetics
BP levels are strongly familial, but no clear genetic pattern exists. Familial risk for cardiovascular diseases (CVDs) should be considered.

RISK FACTORS
Family history, obesity, alcohol use, excess dietary sodium, stress, physical inactivity, tobacco use, insulin resistance, obstructive sleep apnea (OSA)

DIAGNOSIS
● Despite more aggressive guidelines issued by the ACC/AHA in 2017, many experts consider recommendations from JNC 8 (1)[A] to retain primacy.
● Critics of the ACC/AHA guidelines note multiple methodologic concerns, especially the fact the guidelines were heavily influenced by the findings of SPRINT, which was conducted in a relatively high-risk population and therefore less applicable to many patients seen in primary care. Using thresholds of <130/80 mm Hg (as endorsed by AHA/ACC) compared to JNC 8 would result in the diagnosis of and treatment for HTN of millions more people, with unclear benefits and likely harm.
● Therefore, this chapter uses JNC 8 as its basis but focuses on recommendations that are relevant regardless of the specific guideline that is being applied. These include diagnostic considerations and using assessment of overall CV risk to guide treatment decisions.

HISTORY
● HTN is asymptomatic except in extreme cases or after related cardiovascular complications develop.
● Headache can be seen with higher BP, often present on awakening and occipital in location.

PHYSICAL EXAM
● Body mass index (BMI), waist circumference
● BP in both arms (see below for correct technique—essential to accurate diagnosis and treatment)
● Complete cardiac and peripheral pulse exam: Compare radial and femoral pulse for differences in volume and timing (evaluation for aortic coarctation (especially in young persons), subclavian stenosis)
● Funduscopic exam for arteriolar narrowing, AV compression, hemorrhages, exudates, and papilledema

DIFFERENTIAL DIAGNOSIS
● Secondary HTN: Because of the low incidence of reversible secondary HTN, special tests should be considered only if the history, physical exam, or basic laboratory evaluation suggest
a higher likelihood. Also consider for patients who prove nonresponsive to treatment (see “Hypertension, Secondary and Resistant”).

- White coat HTN: elevation of BP in office setting and normal BP outside office
- Masked HTN: elevated BP at home and normal BP in office

**DIAGNOSTIC TESTS & INTERPRETATION**

- Incorrect BP determination is a common cause of overdiagnosis.
- Home blood pressure measurements are better associated with hard outcomes than office values, and also help to mitigate the errors of clinic measurement. Home BP measurement and monitoring should be encouraged.

**ALERT**

- Measuring BP:
  - Caffeine, exercise, and smoking avoided >30 minutes before measurement
  - Patient seated quietly for at least 5 minutes with feet on floor
  - Patient’s arm supported at heart level
  - Correct cuff size
  - Deflate cuff slowly or use an automated device.
  - Average of two or more measurements
  - Avoid “rounding” results.
  - May leave patient alone to obtain in-office readings using an automated or patient-activated cuff

- A diagnosis of HTN should be made when:
  - Age <60 years: SBP ≥140 mm Hg and/or DBP ≥90 mm Hg at ≥2 visits
  - Age ≥60 years: SBP ≥150 mm Hg and/or DBP ≥90 mm Hg at ≥2 visits
  - Age ≥60 years with CKD or diabetes: SBP ≥140 mm Hg and/or DBP ≥90 mm Hg at ≥2 visits

**Initial Tests (lab, imaging)**

- Hemoglobin or hematocrit or complete blood count
- Complete urinalysis (may reveal proteinuria, hematuria/nephritis)
- Potassium, calcium, creatinine, and uric acid
- Lipid panel (total, high-density lipoprotein, low-density lipoprotein, triglyceride)
- Fasting blood glucose or hemoglobin A1c
- ECG to evaluate possible presence of left ventricular hypertrophy (LVH) or rhythm abnormalities

**Follow-Up Tests & Special Considerations**

- Special tests only if suggested by history, physical, or labs. Consider possibility of sleep apnea with high BMI.
- Ambulatory (24-hour) BP monitoring if “white coat” HTN is suspected, episodic HTN, or autonomic dysfunction
- U.K. and U.S. guidelines recognize the importance of confirmation of hypertension using home or ambulatory (24-hour) blood pressure measurement. Ambulatory measurement may be especially helpful if there is suspected autonomic dysfunction.
- CV risk assessment should be performed. The AHA/ACC risk tool likely significantly overestimates risk in many patients (50% or more, especially in multi-ethnic and older patients). Others have used a definition of “low risk” that excludes patients with a history of
CVD, diabetes mellitus, CKD, or familial hypercholesterolemia of premature coronary artery disease.

**TREATMENT**

**GENERAL MEASURES**

- The treatment discussed follows JNC 8 guidelines. Recent systematic reviews and meta-analyses of randomized trials do not support recommendations for lower-than-standard targets for the average-risk population. Potential harms of therapy must be weighed against the potential benefits.

  - **Treatment goals:**
    - Age <60 years: SBP ≥140 mm Hg and/or DBP ≥90 mm Hg
    - Age ≥60 years: SBP ≥150 mm Hg and/or DBP ≥90 mm Hg
    - Age ≥60 years with CKD or diabetes: SBP ≥140 mm Hg and/or DBP ≥90 mm Hg

- More aggressive treatment may be considered in patients meeting enrollment criteria for SPRINT because aggressive treatment does show improvement in outcomes, but 61 nondiabetic patients would need to be treated (NNT) for 3 years to a goal of SBP <120 mm Hg to prevent a major cardiovascular outcome and 90 mm Hg to prevent one death.

- More intensive therapy may be considered for certain high-risk individuals. Even in secondary prevention, no firm conclusions can yet be drawn regarding the comparative effectiveness of intensive vs. standard therapy.

- Individual treatment goals should be jointly established with patients after discussion of the anticipated potential benefits and harms (shared decision making) (1)[A],(2)[A].

- Recommend lifestyle improvements, including diet, exercise, and reducing or eliminating tobacco/alcohol.

- Benefit of pharmacologic treatment of low-risk patients with class I HTN (SBP 140 to 150 mm Hg, DBP 90 to 99 mm Hg) remains uncertain, with harms including syncope, kidney injury, and electrolyte abnormalities. Individualize decisions.

- Treating patients age <60 years or with CKD or diabetes to lower-than-standard BP targets, <140/90 mm Hg, does not appear to further reduce mortality or morbidity. Individualize goal BP based on risk factors and patient preferences.

- A target SBP at or just below 150 mm Hg in patients >60 years of age is acceptable in the general population (1)[A].

- The majority of treatment benefit is attained by lowering high systolic pressures to lower pressures (e.g., from 190 mm Hg to 150 mm Hg, as compared with the benefit of lowering from 150 mm Hg to 136 mm Hg). Striving for small additional drops in BP by adding 3rd, 4th, or 5th medications to achieve a “target” is less clinically beneficial and more likely to cause adverse effects.

- Lower than standard DBP targets are not associated with decreased morbidity/mortality.

**MEDICATION**

- Multiple drugs at submaximal dose may achieve target BP with fewer side effects. In patients on >1 medication, divide between morning and night time for better 24-hour antihypertensive effect.

- Sequential monotherapy attempts should be tried with different classes because individual responses vary.
Many patients will require multiple medications.

For initial monotherapy, choose from 1 of 4 classes of medications: ACE inhibitors, ARBs, calcium channel blockers (CCBs), or diuretics (1).[A]

Thiazide diuretics or CCB preferred as first line in the general black population

Chlorthalidone has a longer half-life than hydrochlorothiazide (HCTZ) and is the preferred diuretic based on established trial evidence of benefit. It is a more potent antihypertensive than HCTZ.

If concomitant conditions, choose first-line agent based on comorbidity.

β-Blockers had been strongly recommended until recent meta-analyses. Atenolol may be particularly ineffective in reducing adverse outcomes of HTN (except in patients with left ventricle hypertrophy undergoing dialysis).

β-Blockers often benefit patients with ischemic heart disease, atrial fibrillation, CHF, migraine, and patients with history of ST-segment elevation myocardial infarction (STEMI).

ACE inhibitors should be used in patients with diabetes, proteinuria, atrial fibrillation, or heart failure with reduced ejection fraction (HFrEF) but not in pregnancy.

α-Adrenergic blockers are not a first choice for monotherapy but remain as second line after combination therapy of first-line agents; might benefit males with benign prostatic hypertrophy (BPH).

CCB could be considered in patients with isolated systolic HTN, atherosclerosis, angina, migraine, or asthma; well documented to reduce risk of stroke

First Line

Thiazide diuretics may not be effective with creatinine clearance <30.
  - Chlorthalidone: 12.5 to 25 mg/day (longer half-life and more potent than hydrochlorothiazide but causes more hyponatremia and hypokalemia). Strongest evidence base for this medication.
  - Hydrochlorothiazide: 12.5 to 50 mg/day
  - Indapamide: 1.25 to 2.5 mg/day
  - Metolazone: 2.5 to 5 mg daily is more effective in patients with impaired renal function than other thiazides, but outcomes studies lacking.

ACE inhibitors
  - Lisinopril: 5 to 40 mg/day
  - Enalapril: 5 to 40 mg/day
  - Ramipril: 2.5 to 20 mg/day
  - Benazepril: 10 to 40 mg/day

CCB
  - Amlodipine: 2.5 to 10 mg/day
  - Nifedipine (sustained release): 30 to 90 mg/day
  - Diltiazem CD: 180 to 360 mg/day
  - Verapamil (sustained release): 120 to 480 mg/day

ARBs
  - Losartan: 25 to 100 mg in 1 or 2 doses; has unique but modest uricosuric effect
  - Valsartan: 80 to 320 mg daily
  - Irbesartan: 75 to 300 mg daily
  - Candesartan: 4 to 32 mg daily
  - Renin inhibitor: aliskiren 150 to 300 mg daily

Contraindications
- Thiazide diuretics may worsen gout.
- β-Blockers (relative) in asthma, heart block, diabetes, and peripheral vascular disease; probably should be avoided in patients with metabolic syndrome or insulin-requiring diabetes
- Diltiazem or verapamil: Do not use with systolic dysfunction or heart block. Amlodipine may cause peripheral edema.

**Second Line**

- Before escalating therapy, ensure that patient is adherent to prescribed regimen.
- Many may be combined. Choose additional medications with complementary effects (i.e., ACE inhibitors/ARBs with diuretic or a vasodilator with a diuretic or β-blocker). Don’t combine ACE inhibitor and ARB.
- Medication-refractory HTN (see Secondary and Resistant Hypertension): Spironolactone 25 to 100 mg/day or eplerenone 50 mg once to twice daily are especially effective.
- Centrally acting α-2 agonists: clonidine 0.1 to 1.2 mg BID or weekly patch 0.1 to 0.3 mg/day, guanfacine 1 to 3 mg daily, or methyldopa 250 to 2,000 mg BID
- α-Adrenergic antagonists: prazosin 1 to 10 mg BID, terazosin 1 to 20 mg/day, or doxazosin 1 to 16 mg/day
- Vasodilators
  - Hydralazine: 10 to 25 mg QID; risk of tachycardia, so generally combined with β-blocker; also drug-induced systemic lupus erythematosus (SLE)
  - Minoxidil: rarely used due to adverse effects; may be more effective than other medications in renal failure and refractory HTN
- Metololzone and loop diuretics may be used with more severe renal impairment, but outcomes data are absent; loop diuretics (for volume overload): furosemide 20 to 320 mg/day or bumetanide 0.5 to 2 mg/day
- K⁺-sparing diuretics in patients with hypokalemia while taking thiazides: amiloride 5 to 10 mg/day or triamterene 50 to 150 mg/day

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Biofeedback and relaxation exercise
- Dietary supplements such as garlic have been suggested for lowering BP, but evidence is lacking.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Reevaluate patients q3–6mo until stable and then q6–12mo. Consider use of home BP self-monitoring; quality-of-life issues including sexual function should be considered.
- Poor medication adherence is a leading cause of apparent medication failure.
- At least annual creatinine and potassium for patients on diuretics, ACE inhibitors, and ARBs

**DIET**

- ~20% of patients will respond to reduced-salt diet (<100 mmol/day; <6 g NaCl or <2.4 g Na).
- Consider Dietary Approaches to Stop HTN (DASH) diet:
Limit alcohol consumption to <1 oz/day.

PATIENT EDUCATION
Counsel for aerobic exercise 5 days a week

COMPLICATIONS
Heart failure, renal failure, LVH, myocardial infarction, retinal hemorrhage, stroke, hypertensive heart disease, drug side effects, erectile dysfunction

CODES
ICD10
I10 Essential (primary) hypertension

CLINICAL PEARLS
- Treatment of HTN reduces risk with NNT to prevent one serious Major Adverse CV Events (MACE).
- Treatment decisions should be informed by BP measured by proper technique; measures outside the clinical office more predictive of CV risk.
- Overly aggressive treatment may cause significant harms, more likely and often more significant in the elderly.
HYPERTENSION, SECONDARY AND RESISTANT
George Maxted, MD

BASICS

DESCRIPTION
Uncontrolled hypertension (HTN) comprises the following entities (see “Alert” below):

- Resistant HTN: defined as blood pressure (BP) that remains above goal in spite of the concurrent use of three antihypertensive agents of different classes. Ideally, one of the three agents should be a diuretic, and all agents should be prescribed at optimal dose amounts (1) [C].
- Secondary HTN: elevated BP that results from an identifiable underlying mechanism (1)
- The 2017 revised American College of Cardiology (ACC)/American Heart Association (AHA) guideline recommends a change in the classification of HTN. For the purposes of this chapter, we will be considering stage 2 HTN: systolic blood pressure (SBP) ≥140 mm Hg or diastolic blood pressure (DBP) ≥90 mm Hg. The guideline is quite controversial (2). See chapter on Hypertension, Essential. Many experts still adhere to the JNC 8 guideline, which allows for a goal of <150/90 mm Hg for patients age >60 years, and disagree with classification of hypertension diagnosis for pressures below 140/90 mm Hg (3)[C].

Geriatric Considerations
- Onset of HTN in adults >60 years of age is a strong indicator of secondary HTN.
- In patients >80 years of age, consider a higher target SBP of ≥150 mm Hg. Be cautious to avoid excessive diastolic lowering.
- Elderly may be particularly responsive to diuretics and dihydropyridine calcium channel blockers.
- Systolic HTN is particularly problematic in the elderly.
- Secondary causes more common in the elderly include sleep apnea, renal disease, renal artery stenosis, and primary aldosteronism (PA).
- Noncompressible arteries (Osler phenomenon)—mostly in elderly with arteriosclerosis: Brachial and radial artery pulsations are present at high cuff pressures.

ALERT
Pseudoresistance:

- Inaccurate measurement of BP
  - Cuff too small
  - Patient not at rest; sitting quietly for 5 minutes
- Poor adherence: In primary care settings, this has been estimated to occur in 40–60% of patients with HTN.
- White coat effect: prevalence 20–40%. Do not make clinical decisions about HTN based solely on measurement in the clinic setting. Home BP monitoring and/or ambulatory BP monitoring is more reliable. See U.S. Preventive Services Task Force (USPSTF) and AHA recommendations (4).
  - Automated office blood pressure (AOBP) is the preferred method of measurement. If AOBP is not possible, home blood pressure measurement (HBPM) is preferred when
making decisions about treatment.

● Inadequate treatment

**EPIDEMIOLOGY**

● Predominant age: In general, HTN has its onset between ages 30 and 50 years. Patients with resistant HTN are more likely to experience the combined outcomes of death, myocardial infarction, congestive heart failure (CHF), stroke, or chronic kidney disease.

● Depending on etiology, age of onset can vary. Age of onset <20 or >50 years increases likelihood of a secondary cause for HTN.

● The strongest predictors for resistant HTN are age (>75 years), presence of left ventricular hypertrophy (LVH), obesity (body mass index [BMI] >30), and high baseline SBP. Other predictors include chronic kidney disease, diabetes, living in the southeastern United States, African American race (especially women), and excessive salt intake.

**Prevalence**

● Prevalence of resistant HTN is unknown. National Health and Nutrition Examination Survey analysis indicates only 53% of adults are controlled to a BP of <140/90 mm Hg. The most common cause of apparently resistant hypertension is likely medication nonadherence.

● Secondary HTN occurs in about 5–10% of adults with chronic HTN.

**ETIOLOGY AND PATHOPHYSIOLOGY**

● Obstructive sleep apnea (25–50%)—results of interventions have been mixed

● Primary hyperaldosteronism (8–20% of resistant HTN cases)

● Chronic renal disease (1–2% of hypertensives)

● Renovascular disease (0.2–0.7%, up to 35% of elderly, 20% of patients undergoing cardiac catheterization)

● Cushing syndrome (<0.1%)

● Pheochromocytoma (0.04–0.1% of hypertensives)

● Other rare causes: hyperthyroidism, hyperparathyroidism, aortic coarctation, intracranial tumor

● Drug-related causes
  – Medications, especially nonsteroidal anti-inflammatory drugs (NSAIDs) (may also blunt effectiveness of angiotensin-converting enzyme inhibitors), decongestants, stimulants (e.g., amphetamines, attention deficit hyperactivity disorder [ADHD] medications), anorectic agents (e.g., modafinil, ephedra, guarana, ma huang, bitter orange), erythropoietin, natural licorice (in some chewing tobacco), yohimbine, glucocorticoids
  – Oral contraceptives: unclear association; mainly epidemiologic and with higher estrogen pills
  – Cocaine, amphetamines, other illicit drugs; drug and alcohol withdrawal syndromes

● Lifestyle factors: Obesity and dietary salt may negate the beneficial effect of diuretics. Excessive alcohol may cause or exacerbate HTN. Physical inactivity also contributes.

**RISK FACTORS**

A recent large cohort study revealed that those with resistant HTN (16.2%) were more likely to be male, Caucasian, older, and diabetic. They were also more likely to be taking β-blockers, calcium channel blockers, and α-adrenergic blockers compared with other drug classes. Factors predictive of resistant or secondary HTN: female sex, African American race, obesity, diabetes, worsening of control in previously stable hypertensive patient, onset in patients age <20 years or >50 years, lack of family history of HTN, significant target end-organ damage, stage 2 HTN
(SBP >160 mm Hg or DBP >100 mm Hg), renal disease, and alcohol or drug use

**GENERAL PREVENTION**
The prevention of resistant and secondary HTN is thought to be the same as for primary or essential HTN: Adopting a Dietary Approaches to Stop Hypertension (DASH) diet, a low-sodium diet, weight loss in obese patients, exercise, limitation of alcohol intake, and smoking cessation may all be of benefit. Relaxation techniques may be of help, but data are limited.

**DIAGNOSIS**

**HISTORY**
- Ask or review at every visit: SANS mnemonic: (i) Salt intake, (ii) Alcohol intake, (iii) NSAID use, (iv) Sleep (author’s suggestion, based on reference listed) (2)
- Review home BP readings; consider ambulatory BP monitoring.
- History will vary with etiology of HTN.
  - OSA: loud snoring while asleep, daytime somnolence
  - Pheochromocytoma: episodes of headache, palpitations, sweating
  - Cushing syndrome: weight gain, fatigue, weakness, easy bruising, amenorrhea
  - Increased intravascular volume: swelling

**PHYSICAL EXAM**
- Ensure that the BP is measured correctly. The patient should be sitting quietly with back supported for at least 5 minutes before measurement. Proper cuff size: bladder encircling at least 80% of the arm. Support arm at heart level. Minimum of two readings at least 1 minute apart. Check BP in both arms. Also check standing BP for orthostasis.
- The USPSTF recommends “obtaining measurements outside of the clinical setting for diagnostic confirmation.” Attention to findings related to possible etiologies: renovascular HTN: systolic/diastolic abdominal bruit; pheochromocytoma: diaphoresis, tachycardia; Cushing syndrome: hirsutism, moon facies, dorsal hump, purple striae, truncal obesity; thyroid disease: enlarged thyroid, tremor, exophthalmos, tachycardia; coarctation of the aorta: upper limb HTN with decreased or delayed femoral pulses
- Check pulses, heart auscultation, legs for edema

**DIFFERENTIAL DIAGNOSIS**
Pseudoresistance

**DIAGNOSTIC TESTS & INTERPRETATION**
- ECG performed as part of the initial workup; LVH is an important marker of resistant HTN.
- Sleep study if history and physical indicate. The Epworth Sleepiness Scale is recommended.
- Home-based polysomnography has been shown to be accurate in screening for OSA. Overnight oximetry is not helpful.

**Initial Tests (lab, imaging)**
Initial limited diagnostic testing should include urinalysis, CBC, potassium, sodium, glucose, creatinine, lipids, thyroid-stimulating hormone (TSH), and calcium. 50% of patients with hyperaldosteronism may have normal potassium levels.
- Imaging tests listed are necessary only if history, physical, or lab data indicate.
Abdominal US: if renal disease is suspected
- Duplex ultrasonography may be the preferred test for renovascular disease. MR angiography (MRA) of renal vasculature is sensitive but has low specificity and potentially more harmful. Conventional catheter angiography or CT angiography may be required to confirm the diagnosis.
- Adrenal “incidentaloma” frequently arises in this era of multiple CT studies. If present in the setting of resistant HTN, consider hyperaldosteronism or hyperadrenal corticoid states.

Follow-Up Tests & Special Considerations
Further testing for PA may be considered.
- Empiric treatment with an aldosterone inhibitor may be preferable and more clinically relevant: spironolactone or eplerenone. Amiloride may be more effective in African Americans.
- Plasma aldosterone-to-renin ratio (ARR) is the preferred lab test, but the test is difficult to perform and interpret properly. Consult your reference lab and interpret results with caution.
  - Further testing for pheochromocytoma: plasma metanephrines
  - Other tests to consider for resistant or secondary HTN: 24-hour urine for free cortisol, calcium, parathyroid hormone (PTH), overnight 1-mg dexamethasone suppression test, urine toxicology screen

Diagnostic Procedures/Other
Consider 24-hour ambulatory BP monitoring (ABPM), especially if white coat effect is suspected. Home BP monitor results predict mortality, stroke, and other target organ damage better than office BP. Optimal protocol involves two paired measurements: morning and evening (four measurements) over 4 to 7 days.
- Oscillometric, electronic, upper arm, fully automatic device with memory: average multiple readings over several days
- See http://www.dableducational.org/ for validated monitors.

TREATMENT
- Treatment modality depends on etiology of HTN. Please see each etiology listed for information on proper treatment.
- Emphasize adherence to JNC 8 and/or AHA/ACC guidelines, with emphasis on lifestyle modification (2,3)[C].
  - Obese patients, African Americans, and elderly may be particularly responsive to diuretics.
  - Tolerance to diuretics may occur: long-term adaptation to thiazides or the “braking effect.” Consider increasing the dose of thiazide or adding an aldosterone inhibitor.
- Treatment specific to certain secondary etiologies
  - PA: aldosterone receptor antagonist: spironolactone or eplerenone
  - Cushing syndrome: aldosterone receptor antagonist
  - OSA: continuous positive airway pressure (CPAP) ± oxygen, surgery, weight loss
    - Mandibular advancement devices may be equally effective in some patients.
  - Nocturnal hypoxia: oxygen supplementation
  - Renal sympathetic denervation is controversial as current approaches have largely failed to demonstrate clinical benefit. New techniques/approaches are under study.
The treatment of atherosclerotic renal artery stenosis (ARAS) is controversial. A recent meta-analysis again questions the value of percutaneous stenting (5)[B].

**MEDICATION**
- Follow treatment guidelines and algorithms by JNC 8 and AHA/ACC/CDC, understanding the differences between them (2,3)[C].
- Adding a medication to the regimen may have greater efficacy than increasing the dose of medications (see JNC 8 management algorithm option B) (3).
- Aldosterone antagonists may offer significant benefit (6)[B].
- Central-acting agents (e.g., clonidine) are effective at reducing BP, but outcome data are lacking.

**ALERT**
- Agents specific for treatment of HTN emergencies should be initiated in those situations, in which immediate BP reduction will prevent or limit end-organ damage (see “Hypertensive Emergencies”).
- Renovascular HTN: Angioplasty is the treatment of choice for fibromuscular dysplasia of a renal artery.
- The recent CORAL study concluded that in patients with atherosclerotic renovascular disease and HTN, renal artery stenting did not improve outcomes over medical therapy alone.
- Referral to an HTN specialist or clinic: Retrospective studies indicate improved control rates for patients with resistant HTN referred to special HTN clinics.

**First Line**
- For non-black patients: thiazide diuretics, ACEi or angiotensin receptor blocker (ARB) (not both), calcium channel blocker (CCB)
- For black patients: thiazide diuretics, CCBs. Hydralazine and isosorbide mononitrate or dinitrate are options.

**Second Line**
Combine thiazide diuretic with ACEi, ARB, or CCB or add a K⁺-sparing diuretic. β-Blockers—especially if compelling indication such as ischemic heart disease or CHF—migraine and tachyarrhythmias may also be indications.

**Third Line**
Add agent not used in second line; if this does not adequately lower BP, initiate workup for secondary causes (chronic NSAID use, alcohol abuse, recurrent aphthous stomatitis, etc.).

**ADDITIONAL TREATMENT**
Nondrug interventions, other than standard lifestyle modifications, may be helpful.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
The University of Wisconsin Integrative Medicine program has an excellent handout and patient information.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Hospitalization may be necessary for hypertensive urgency or emergency general measures.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Encourage aerobic activity of 30 min/day, depending on patient’s condition.

DIET
- Reduced salt may lower BP in some patients.
- Recommend the Mediterranean diet or DASH.

PATIENT EDUCATION
Home BP monitoring is recommended.

CODES
ICD10
- I15.9 Secondary hypertension, unspecified
- I15.8 Other secondary hypertension
- I15.0 Renovascular hypertension

CLINICAL PEARLS
- Onset of HTN in adults >60 years of age is a strong indicator of secondary HTN.
- Common causes of resistant HTN: OSA, excessive salt intake, medication nonadherence, alcohol, NSAIDs
- Common secondary causes include sleep apnea, renal disease, renal artery stenosis, and PA.
- Aldosterone inhibitors should be considered in all cases of resistant HTN.
- Home BP monitoring predicts outcomes better than office monitoring of BP.
HYPERTHYROIDISM
Anup Sabharwal, MD, MBA, FACE

BASICS
- Hyperthyroidism or thyrotoxicosis is composed of a spectrum of clinical findings consistent with thyroid hormone excess. The former describes excess from the thyroid gland, whereas the latter can also be produced from another source.
- In general, patients with thyrotoxicosis have hyperthyroidism. However, this is not always the case. Patients could suffer from thyrotoxicosis subacute thyroiditis, exogenous thyrotoxicosis, and radiation-induced thyroiditis.
- Also, medications (such as amiodarone and interferon-α) have cytotoxic effects on thyroid cells resulting in thyrotoxicosis from preformed thyroid hormones.

DESCRIPTION
- Graves disease (GD): the most common form; diffuse goiter and thyrotoxicosis are common characteristics. Infiltrative orbitopathy is seen in up to 50% of patients. Infiltrative dermopathy is rare (1). Autoantibodies are directed at the thyroid-stimulating hormone (TSH) receptors.
- Toxic multinodular goiter (TMNG): second most common; most common cause of hyperthyroidism in patients age >65 years; patients >40 years, insidious onset, frequent in iodine-deficient areas.
- Toxic adenoma (Plummer disease): younger patients, autonomously functioning nodules.
- Iodine-induced hyperthyroidism.
- Thyroiditis: transient autoimmune process:
  - Subacute thyroiditis/de Quervain: granulomatous giant cell thyroiditis, benign course; viral infections have been involved.
  - Postpartum thyroiditis.
  - Drug-induced thyroiditis: amiodarone, interferon-α, interleukin-2, lithium.
  - Miscellaneous: thyrotoxicosis factitia, TSH-secreting pituitary tumors, and functioning trophoblastic tumors (2)[B]
- Subclinical hyperthyroidism: suppressed TSH with normal thyroxine (T₄); may be associated with osteoporosis and atrial fibrillation.
- Thyroid storm: rare hyperthyroidism; fever, tachycardia, gastrointestinal (GI) symptoms, central nervous system dysfunction (e.g., coma); up to 50% mortality.

Geriatric Considerations
- Characteristic symptoms and signs may be absent.
- Atrial fibrillation is common when TSH <0.1 mIU/L (3)[A].

Pediatric Considerations
- Neonates and children are treated with antithyroid medications for 12 to 24 months.
- Radioactive iodine treatment is controversial in patients <15 to 18 years.

Pregnancy Considerations
Propylthiouracil is currently the drug of choice during 1st trimester of pregnancy, and methimazole is preferred in the 2nd and 3rd trimester (4)[A]. Treat with lowest effective dose.
Avoid treatment-induced hypothyroidism. Radioiodine therapy is contraindicated.

**EPIDEMIOLOGY**
- 1.3% of population
- Predominant sex: female > male (7 to 10:1)
- Predominant age: autoimmune thyroid disease (GD) in 2nd and 3rd decades; TMNG more common in patients >40 years

**Incidence**
- Female: 1/1,000
- Male: 1/3,000

**Prevalence**
The prevalence of hyperthyroidism is 1.3% and can increase in older women to 4–5%.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- GD: autoimmune disease
- TMNG: 60% TSH receptor gene abnormality; 40% unknown
- Toxic adenoma: point mutation in TSH receptor gene with increased hormone production
- Thyroiditis:
  - Hashitoxicosis: autoimmune destruction of the thyroid; antimicrosomal antibodies present
  - Subacute/de Quervain thyroiditis: granulomatous reaction; genetic predisposition in specific human leukocyte antigens; viruses, such as coxsackievirus, adenovirus, echovirus, and influenza virus, have been implicated; self-limited course, 6 to 12 months
  - Suppurative: infectious
  - Drug-induced thyroiditis: Amiodarone produces an autoimmune reaction and a destructive process. Lithium, interferon-α, and interleukin-2 cause an autoimmune thyroiditis.
  - Postpartum thyroiditis: autoimmune thyroiditis that lasts up to 8 weeks, and in 60% of patients, hypothyroidism manifests in the future

**Genetics**
Concordance rate for GD among monozygotic twins is 35%.

**RISK FACTORS**
- Positive family history, especially in maternal relatives
- Female
- Other autoimmune disorders
- Iodide repletion after iodide deprivation, especially in TMNG

**COMMONLY ASSOCIATED CONDITIONS**
- Autoimmune diseases
- Down syndrome
- Iodine deficiency

**DIAGNOSIS**

**HISTORY**
- Thyrotoxicosis is a hypermetabolic state in which energy production exceeds needs, causing
increased heat production, diaphoresis, and even fever.

- Thyrotoxicosis affects several different systems:
  - Constitutional: fatigue, weakness, increased appetite, weight loss
  - Neuropsychiatric: agitation, anxiety, emotional lability, psychosis, coma, and poor concentration and memory
  - GI: increased appetite, hyperdefecation
  - Gynecologic: oligomenorrhea, amenorrhea
  - Cardiovascular: tachycardia (most common) and chest discomfort that mimics angina

**Geriatric Considerations**
Apathetic hyperthyroidism in the elderly

**PHYSICAL EXAM**

- Adults:
  - Skin: warm, moist, pretibial myxedema (GD only)
  - Head, eye, ear, nose, throat (HEENT): exophthalmos, lid lag
  - Endocrine: hyperhidrosis, heat intolerance, goiter, gynecomastia, and spider angiomata (males)
  - Cardiovascular: tachycardia, atrial fibrillation, cardiomegaly
  - Musculoskeletal: fractures
  - Neurologic: tremor, proximal muscle weakness, anxiety and lability, brisk deep tendon reflexes
  - Rarely: thyroid acropachy (clubbing), localized dermopathy

- Children:
  - Linear growth acceleration
  - Ophthalmic abnormalities more common

**DIFFERENTIAL DIAGNOSIS**

- Anxiety
- Malignancy
- Diabetes mellitus
- Pregnancy
- Menopause
- Pheochromocytoma
- Depression
- Carcinoid syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

- 95% have suppressed TSH and elevated free T4. Total T4 and triiodothyronine (T3) represent the bound hormone and can be affected by pregnancy and hepatitis (2)[A].

- T3: elevated, especially in T3 toxicity or amiodarone-induced thyrotoxicosis (AIT): Presence of TSH receptor antibody or thyroid-stimulating immunoglobulin is diagnostic of GD.

- Free thyroxine index (FTI): calculated from T4 and thyroid hormone–binding ratio; corrects for misleading results caused by pregnancy and estrogens

- Inappropriately normal or elevated TSH with high T4 suspicious for pituitary tumor or thyroid hormone resistance

- Drugs may alter lab results: estrogens, heparin, iodine-containing compounds (including
amiodarone and contrast agents), phenytoin, salicylates, and steroids (e.g., androgens, corticosteroids).

- Exogenous biotin supplements can interfere with immunoassays for thyroid hormones, TSH, thyroglobulin, and TSH receptor binding inhibiting antibody (5)[B].
- Drug precautions: Amiodarone and lithium may induce hyperthyroidism; methimazole may cause warfarin resistance.
- Other findings that can occur: anemia, granulocytosis, lymphocytosis, hypercalcemia, transaminase, and alkaline phosphate elevations

**Initial Tests (lab, imaging)**

- TSH, free $T_4$, total $T_4$, and $T_3$ will establish the hyperthyroid diagnosis (6)[A].
- Thyrotropin receptor antibody (TRAb) (7)[A]
- TSH receptor antibodies (TSH-R Abs): The routine assay is the TSH-binding inhibitor immunoglobulin assay (TBII). TSH-R Abs are useful in the prediction of postpartum Graves thyrotoxicosis and neonatal thyrotoxicosis (6)[A].
- Thyroxine/triiodothyronine ratio: The $T_4$-to-$T_3$ ratio may be a useful tool when the iodine uptake testing is not available/contraindicated. ~2% of thyrotoxic patients have “$T_3$ toxicosis.”
- Nuclear medicine uptake and scanning ($^{123}$I or $^{131}$I): The reference-range value for 24-hour radioiodine uptake is between 5% and 25%.
- Increased thyroid iodine uptake is seen with TMNG, toxic solitary nodule, and GD.
- GD shows a diffuse uptake and can have a paradoxical finding of high uptake at 4 to 6 hours but normal uptake at 24 hours because of the rapid clearance.
- TMNG will show a heterogeneous uptake, whereas solitary toxic nodule will show a warm or “hot” nodule.
- In iodine-deficient areas, an increased uptake is associated with low urine iodine levels.
- Causes of thyrotoxicosis with low iodine uptake:
  - Acute thyroiditis, thyrotoxicosis factitia, and iodine intoxication with amiodarone or contrast material can cause low-uptake transient thyrotoxicosis. After thyroiditis resolves, the patient can become euthyroid or hypothyroid.
  - Iodine loading can cause iodine trapping and decreased iodine uptake (Wolff-Chaikoff effect).
  - Thyrotoxicosis factitia: Thyroglobulin levels are low in exogenous intake and high in endogenous production.
  - Other extrathyroidal causes include struma ovarii and metastatic thyroid carcinoma.
  - Technetium-99m scintigraphy: controversial because it has a 33% discordance rate with radioactive iodine scanning

**Follow-Up Tests & Special Considerations**

In severe cases, such as thyroid storm, hospitalize until stable, especially if >60 years of age, because of the risk of atrial fibrillation.

**Diagnostic Procedures/Other**

Neck ultrasound will show increased diffuse vascularity in GD.

**Test Interpretation**

- GD: hyperplasia
- Toxic nodule: nodule formation
TREATMENT

- Decision of which patients to treat and how to treat should be individualized.
- Observation may be appropriate for patients with mild hyperthyroidism (TSH >0.1 or with no symptoms) especially those who are young and with low risk of complications (atrial fibrillation, osteoporosis).
- Antithyroid medication is contraindicated in patients with thyroiditis. Treatment for subacute thyroiditis is supportive with NSAIDs and β-blockers. Steroids can be used for 2 to 3 weeks (4). GD or TMNG can be managed by either antithyroid medication, radioactive iodine therapy (RAIT), or thyroidectomy.
- RAIT: most common definitive treatment used in United States for GD and TMNG
- Pretreatment with antithyroid drugs is preferred to avoid worsening thyrotoxicosis after RAIT. Methimazole is preferred over propylthiouracil as pretreatment because of decreased relapse, but it is held 3 to 5 days before therapy (4)[A].
- Usually, patients become hypothyroid 2 to 3 months after RAIT; therefore, antithyroid medications are continued after ablation.
- Glucocorticoids: reduce the conversion of active T$_4$ to the more active T$_3$. In Graves ophthalmopathy, the use of prednisone before and after RAIT prevents worsening ophthalmopathy (4)[B].
- Smoking in GD patients is a risk factor for ophthalmopathy, especially after RAIT.
- For GD, due to the chance of remission, 12- to 18-month trial of antithyroid medications may be considered prior to offering RAIT.
- For TMNG, the treatment of choice is RAIT. Medical therapy with antithyroid medications has shown a high recurrence rate. Surgery is considered only in special cases (4)[B].
- For AIT type I, the treatment is antithyroid drugs and β-blockers. Thyroidectomy is the last option. AIT type II is self-limited but may use glucocorticoids.

MEDICATION

First Line

- Antithyroid drugs: Methimazole and propylthiouracil are thioamides that inhibit iodine oxidation, organification, and iodotyrosine coupling. Propylthiouracil can block peripheral conversion of T$_4$ to active T$_3$. Both can be used as primary treatment for GD and prior to RAIT or surgery (2)[A].
- Duration of treatment: 12 to 18 months; 50–60% relapse after stopping; treatment beyond 18 months did not show any further benefit on remission rate. The most serious side effects are hepatitis (0.1–0.2%), vasculitis, and agranulocytosis; baseline CBC recommended:
  - Methimazole (preferred): adults: 10 to 15 mg q12–24h; children aged 6 to 10 years: 0.4 mg/kg/day PO once daily
  - Propylthiouracil: adults (preferred in thyroid storm and 1st trimester of pregnancy): 100 to 150 mg PO q8h, not to exceed 200 mg/day during pregnancy
- β-Adrenergic blocker: Propranolol in high doses (>160 mg/day) inhibits T$_3$ activation by up to 30%. Atenolol, metoprolol, and nadolol can be used and are also useful in relieving palpitations and in slowing the heart rate in patients with sinus tachycardia (1)[A].
- Glucocorticoids: reduce the conversion of active T$_4$ to the more active T$_3$
- Cholestyramine: anion exchange resin that decreases thyroid hormone reabsorption in the
enterohepatic circulation; dose: 4 g QID (2)[B]

Other agents:
- Lithium: inhibits thyroid hormone secretion and iodotyrosine coupling; use is limited by toxicity.
- Lugol solution or saturated solution of potassium iodide (SSKI); blocks release of hormone from the gland but should be administered at least 1 hour after thioamide was given; otherwise, acts as a substrate for hormone production (Jod-Basedow effect)
- RAIT: See “Treatment” section.

ISSUES FOR REFERRAL
Patients with Graves ophthalmopathy should be referred to an experienced ophthalmologist.

SURGERY/OTHER PROCEDURES
Thyroidectomy for compressive symptoms, masses, and thyroid malignancy may be performed in the 2nd trimester of pregnancy only.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Repeat thyroid tests q3mo, CBC, and liver function tests (LFTs) on thioamide therapy; continue therapy with thioamides for 12 to 18 months.
- After RAIT, thyroid function tests at 6 weeks, 12 weeks, 6 months, and annually thereafter if euthyroid; TSH may remain undetectable for months even after patient is euthyroid; follow \( T_3 \) and \( T_4 \).

DIET
Sufficient calories to prevent weight loss

PROGNOSIS
Good (with early diagnosis and treatment)

COMPLICATIONS
- Surgery: hypoparathyroidism, recurrent laryngeal nerve damage, and hypothyroidism
- RAIT: postablation hypothyroidism
- GD: high relapse rate with antithyroid drug as primary therapy
- Graves ophthalmopathy, worsening heart failure if cardiac condition, atrial fibrillation, muscle wasting, proximal muscle weakness, increased risk of cerebrovascular accident (CVA), and cardiovascular mortality

REFERENCES
2. Bahn Chair RS, Burch HB, Cooper DS, et al; for American Thyroid Association, American

**CODES**

**ICD10**

- E05.90 Thyrotoxicosis, unspecified without thyrotoxic crisis or storm
- E05.20 Thyrotoxicosis w toxic multinod goiter w/o thyrotoxic crisis
- E06.1 Subacute thyroiditis

**CLINICAL PEARLS**

- Not all thyrotoxicoses are secondary to hyperthyroidism.
- GD presents with hyperthyroidism, ophthalmopathy, and goiter.
- Medical treatment for GD has a high relapse rate after stopping medications.
- Thyroid storm is a medical emergency that needs hospitalization and aggressive treatment.
- Serum TSH level may be misleading and remain low in the early period after initiating treatment, even when T_4 and T_3 levels have decreased.
HYPERTTRIGLYCERIDEMIA
S. Lindsey Clarke, MD, FAAFP

BASICS

DESCRIPTION
- Hypertriglyceridemia (HTG) is a common form of dyslipidemia characterized by an excess fasting plasma concentration of triglycerides (TGs).
  - TGs are fatty molecules that occur naturally in vegetable oils and animal fats and are major sources of dietary energy.
  - Absorbed TGs are packaged into very low-density lipoproteins (VLDL) and chylomicrons.
- HTG is independently associated with cardiovascular disease at levels ≥175 mg/dL.
  - The degree to which excess TGs cause atherosclerosis is debatable.
  - The American Heart Association (AHA) and the American College of Cardiology (ACC) consider persistent HTG a risk-enhancing factor.
  - A large Danish population study in 2018 showed that TG ≥264 mg/dL conferred a 10-year risk of major adverse cardiovascular events comparable to that of statin eligible individuals.
  - However, lowering TG has not been proven to reduce cardiovascular risk.
- HTG also is a risk factor for acute pancreatitis at levels ≥500 mg/dL and especially ≥1,000 mg/dL.
  - Risk is 10–20% at these TG levels.
  - Third leading cause of acute pancreatitis
- American Heart Association (AHA) and American College of Cardiology (ACC) classify HTG into two categories:
  - Moderate: 175 to 499 mg/dL (2.0 to 5.6 mmol/L), characterized mainly by excess VLDL
  - Severe: ≥500 mg/dL (≥5.6 mmol/L), characterized by excess VLDL and chylomicrons

EPIDEMIOLOGY
- Predominant gender: male > female
- Predominant race: Hispanic, white > black

Prevalence
- 33% of U.S. population has TG levels ≥150 mg/dL.
- 1.7% has TG levels ≥500 mg/dL.
- Highest prevalence at age 50 to 70 years
- The most common genetic syndromes with HTG, familial combined hyperlipidemia and familial HTG, each affect ≤1% of general population.

ETIOLOGY AND PATHOPHYSIOLOGY
- Primary
  - Familial
  - Acquired (sporadic)
- Secondary
  - Lifestyle factors
    - Obesity and overweight
    - Metabolic syndrome/insulin resistance
- Physical inactivity
- Cigarette smoking
- Excess alcohol intake
- Very high carbohydrate diets (>60% of total caloric intake)

- Medical conditions
  - Type 2 diabetes mellitus
  - Hypothyroidism
  - Chronic liver disease
  - Chronic kidney disease, nephrotic syndrome
  - Autoimmune disorders (e.g., systemic lupus erythematosus)
  - Paraproteinemias (e.g., macroglobulinemia, myeloma, lymphoma, lymphocytic leukemia)
  - Pregnancy (usually physiologic and transient)

- Certain medications
  - Atypical antipsychotics (e.g., quetiapine)
  - β-Blockers other than carvedilol
  - Bile acid sequestrants
  - Cyclophosphamide
  - Cyclosporine
  - Glucocorticoids
  - Interferon
  - Oral estrogens
  - Protease inhibitors (e.g., ritonavir, darunavir)
  - Retinoids
  - Rosiglitazone
  - Tamoxifen and raloxifene
  - Thiazides

Genetics
- Familial chylomicronemia (type 1 dyslipidemia): autosomal recessive inheritance of lipoprotein lipase deficiency; 0.0001% population prevalence
- Familial combined hyperlipidemia (type IIb): usually autosomal dominant, caused by overproduction of apolipoprotein (APO) B-100; approximately 1% prevalence
- Familial dysbetalipoproteinemia (type III): usually autosomal recessive, caused by lipoprotein overproduction due to inheritance of two APOE2 variants; 0.01% prevalence
- Familial HTG (type IV): autosomal dominant, caused by an inactivating mutation of the lipoprotein lipase gene; 1% prevalence
- Primary mixed HTG (type V)

RISK FACTORS
- Genetic susceptibility
- Obesity, overweight
- Lack of exercise
- Diabetes
- Alcoholism
- Certain medical conditions and drugs (see “Etiology and Pathophysiology”)

GENERAL PREVENTION
• Maintain healthy body weight
• Moderation of dietary fat and refined carbohydrates
• Regular aerobic exercise
• Avoid excess alcohol

COMMONLY ASSOCIATED CONDITIONS
• Coronary artery disease
• Diabetes mellitus type 2 and insulin resistance
• Dyslipidemias
  – Decreased high-density lipoprotein (HDL) cholesterol
  – Increased low-density lipoprotein (LDL), non-HDL, and total cholesterol
  – Small, dense LDL particles
• Metabolic syndrome (three of the following):
  – Abdominal obesity (waist circumference >40 inches in men, >35 inches in women)
  – TG ≥150 mg/dL
  – Low levels of HDL cholesterol (<40 mg/dL in men, <50 mg/dL in women)
  – BP ≥130/85 mm Hg
  – Fasting glucose ≥100 mg/dL
• Nonalcoholic steatohepatitis
• Pancreatitis
• Polycystic ovary syndrome

DIAGNOSIS

HISTORY
• Usually asymptomatic
• Patients with chylomicronemia syndrome can have memory loss, headache, vertigo, dyspnea, and paresthesias.
• Pancreatitis: epigastric pain, nausea, and vomiting
• Assess for other cardiac risk factors.
• Family history of coronary artery disease

PHYSICAL EXAM
• Obesity, overweight (body mass index ≥25 kg/m²)
• Eruptive cutaneous, tuberous, and striate palmar xanthomas
• Lipemia retinalis
• Epigastric tenderness in pancreatitis
• Hepatomegaly in nonalcoholic steatohepatitis and chylomicronemia

DIFFERENTIAL DIAGNOSIS
Primary and secondary HTG

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Serum: turbid with milky supernatant
• Fasting (12 hours) or nonfasting lipid profile
  – American Academy of Pediatrics recommends screening all children for high cholesterol at
9 to 11 years of age, a controversial recommendation.

- U.S. Preventive Services Task Force recommends screening adults aged 40 to 75 years to identify dyslipidemia and to calculate 10-year atherosclerotic cardiovascular disease (ASCVD) risk; repeat every 5 years.
- Note that statin therapy may be indicated for LDL and ASCVD risk reduction in some adults (e.g., clinical ASCVD, diabetes) regardless of lipid levels.
- Confirm severe HTG with fasting measurement.
- For interpretation, see “Description.”

● Evaluation for secondary causes
  - Glycosylated hemoglobin, fasting or postprandial glucose for type 2 diabetes mellitus
  - Creatinine, urinary protein measurement for nephrotic syndrome, renal failure
  - Thyroid-stimulating hormone for hypothyroidism
  - Human chorionic gonadotropin for pregnancy

● Atherosclerosis: cardiac stress imaging, coronary angiography, computed tomography (CT) arteriography

● Pancreatitis: serum lipase; CT scan, ultrasound of pancreas

**Follow-Up Tests & Special Considerations**

- Repeat lipid panel after 2 months of therapy.
- High levels of apoB (>130 mg/dL) are a strong predictor of coronary death in patients whose LDL cannot be calculated because of very high TGs. Consider if TG ≥200 mg/dL. However, evidence for routine clinical use is lacking.

**TREATMENT**

**GENERAL MEASURES**

- Cardiovascular risk reduction through LDL lowering should be prioritized over TG lowering unless patient is at risk for pancreatitis because of very high TG (≥500 mg/dL) (1)[C].
- Therapeutic lifestyle changes are first-line interventions for all patients and can reduce TG by as much as 50%:
  - Dietary modification (by decreasing carbohydrate intake to <50% of calories and limiting alcohol intake)
  - Moderate-intensity physical activity can reduce TG by 20–30%.
  - Weight loss of 5–10% can reduce TG by 20%.
  - Persons with very high TG should abstain from alcohol.
- Search for correctable secondary causes, treat underlying illness, or remove offending drug.
- Improve glycemic control if diabetic.
- Control other cardiac risk factors, such as hypertension, diabetes mellitus, and smoking.
- Primary HTG: Screen other family members.

**MEDICATION**

**First Line**

- Statins: the most effective agents for reducing cardiovascular risk; primarily affect LDL but also may lower TG 15–30% (2)[A]; dosing depends on intensity of statin desired based on 10-year ASCVD risk; 2018 ACC/AHA guidelines recommend initiating therapy for 10-year ASCVD risk ≥7.5% and other clinical factors (1)[C]. Other U.S. and European guidelines
favor initiation at higher risk levels. See Coronary Artery Disease and Stable Angina: and Hypercholesterolemia.

- Rosuvastatin: 5 to 40 mg/day
- Atorvastatin: 10 to 80 mg/day
- Adverse reactions: myalgias, myopathy, rhabdomyolysis (especially if combined with fibrates); contraindicated in pregnancy and lactation

- Fibrates: the most effective agents for reducing TG up to 50%; used primarily to reduce risk of pancreatitis in severe HTG; have been shown to decrease nonfatal myocardial infarction but not all-cause mortality (3)[A]:
  - Fenofibrate: 30 to 200 mg daily
  - Gemfibrozil: 600 mg BID
  - Adverse reactions: GI upset, hepatotoxicity, cholelithiasis, myalgias, rhabdomyolysis (when combined with a statin), gemfibrozil-warfarin interaction (enhanced anticoagulation)
  - Gemfibrozil should be avoided in combination with statins due to high risk of muscle injury. If combination therapy is needed, cautiously use fenofibrate.

Second Line
Omega-3 fatty acids
- Lovaza, Vascepa, others: 4 g daily or 2 g BID
- May lower TG 30–50%
- Limited tolerability due to adverse GI effects (diarrhea in up to 15%; also nausea, abdominal pain, dysgeusia, eructation, dyspepsia)
- Conflicting outcomes data (4)[A],(5)[A]

ISSUES FOR REFERRAL
- HTG refractory to treatment
- Familial HTG syndromes

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Acute pancreatitis
- Acute coronary syndrome
- In acute hypertriglyceridemic pancreatitis with TG >1,000 mg/dL, the following interventions can be used to lower TG rapidly and safely to <500 mg/dL:
  - Apheresis (therapeutic plasma exchange) for 1 to 3 days
  - Insulin infusion
    - Regular insulin 0.1 to 0.3 U/kg/hr IV for 2 to 4 days
    - Administer separate infusion of dextrose 5% if blood glucose <200 mg/dL.
- Discharge criteria: stabilization of acute complicating illness

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
2 months after initiation or modification of therapy (repeat fasting lipid profile)

Patient Monitoring
- Fasting lipid profile q6–12mo
- Maintain TG <500 to 1,000 mg/dL to reduce risk of acute pancreatitis.
• Hepatic transaminases
• Creatine phosphokinase if patient has myalgias

**DIET**

• Restrict dietary fat to 30% of total caloric intake; restrict further to 15% of caloric intake if TG ≥1,000 mg/dL.
• Limit carbohydrates (especially simple carbohydrates and sugars) to 60% of total caloric intake.
• Mediterranean-style diet reduces TG 10–15% more than a low-fat diet.
• Increase marine-derived omega-3 polyunsaturated fatty acids (4 g/day reduces TG by 25–30%, dose–response relationship). Eat fatty fish.
• Eliminate trans fatty acids.
• Increase dietary fiber.
• Avoid refined carbohydrates.
• Moderate alcohol intake (<1 oz/day) or complete abstinence if TGs are very high

**PATIENT EDUCATION**

Smoking cessation for cardiovascular risk reduction

**PROGNOSIS**

• Good with correction of TG levels
• Patients with primary HTG usually require lifelong treatment.

**COMPLICATIONS**

• Atherosclerosis
• Chylomicronemia syndrome
• Pancreatitis

**REFERENCES**

**ADDITIONAL READING**

SEE ALSO
- Hypercholesterolemia; Pancreatitis, Acute
- Algorithm: Hypertriglyceridemia

CODES

ICD10
E78.1 Pure hyperglyceridemia

CLINICAL PEARLS
- HTG is a risk factor for atherosclerosis at levels ≥175 mg/dL and for acute pancreatitis at levels ≥500 to 1,000 mg/dL.
- Therapeutic lifestyle interventions (diet and exercise) are recommended for all patients who have HTG and for all patients at risk for ASCVD.
- Address reversible secondary causes of HTG.
- In patients with TG levels <500 mg/dL, the primary pharmacologic strategy for cardiovascular risk management is statins.
- For patients with TG levels ≥500 mg/dL, the greatest amount of TG lowering is achieved with fibrates; however, the magnitude of clinical benefit is uncertain.
HYPOGLYCEMIA, DIABETIC
Joseph A. Florence, MD • Emily K. Flores, PharmD, BCPS

BASICS

DESCRIPTION
- Abnormally low concentration of glucose in circulating blood of a patient with diabetes mellitus (DM); often referred to as an insulin reaction
- Classification of hypoglycemia (1):
  - Level 1: hypoglycemia alert value. <70 mg/dL (3.9 mmol/L): may or may not be accompanied by symptoms; asymptomatic hypoglycemia if symptoms not present
  - Level 2: clinically significant hypoglycemia. <54 mg/dL (3.0 mmol/L)
  - Level 3: severe hypoglycemia. No specific glucose threshold: hypoglycemia associated with severe cognitive impairment requiring external assistance for recovery
- Probable symptomatic hypoglycemia: event with symptoms but glucose not tested
- Pseudohypoglycemia: an event with typical symptoms but glucose ≥70 mg/dL (3.9 mmol/L)
- Hypoglycemia is the leading limiting factor in the glycemic management of type 1 DM (T1DM) and type 2 DM (T2DM). Severe or frequent hypoglycemia requires modification of treatment regimens, including higher treatment goals.

ALERT
Severe hypoglycemia associated with increased mortality
- Hypoglycemia unawareness
  - Major risk factor for severe hypoglycemic reactions
  - Most commonly found in patients with long-standing T1DM and children age <7 years

EPIDEMIOLOGY
Incidence
- From the ACCORD study, the annual incidence of hypoglycemia was the following:
  - 3.14% in the intensive treatment group
  - 1.03% in the standard group
  - Increased risk among women, African Americans, those with less than high school education, aged participants, and those who used insulin at trial entry
- From the RECAP-DM study: Hypoglycemia was reported in 35.8% of patients with T2DM who added a sulfonylurea or thiazolidinedione to metformin therapy during the past year.

ETIOLOGY AND PATHOPHYSIOLOGY
- Loss of hormonal counterregulatory mechanism in glucose metabolism
- Too little food (skipping or delaying meals), decreased CHO intake
- Too much insulin or oral hypoglycemic agent (improper dose, timing, or erratic absorption)
- Unplanned or excessive exercise/physical activity
- Alcohol consumption
- Vomiting or diarrhea

RISK FACTORS
Nearly 3/4 of severe hypoglycemic episodes occur during sleep.

Severe hypoglycemia is associated with comorbid conditions in patients age ≥65 years and in users of a long-acting sulfonylurea.

Intensive insulin therapy (further lowering HgbA1C from 7% to 6%) is associated with higher rate of hypoglycemia.

Comorbidities: renal/liver disease, congestive heart failure (CHF), hypothyroidism, hypoadrenalism, gastroenteritis, gastroparesis (unpredictable CHO delivery), autonomic neuropathy, pregnancy, anxiety, depression, disordered eating behavior, illness/stress, and unplanned life events.

Duration of DM >5 years

Young children with type 1 diabetes

Advanced age

Reduced cognitive function, dementia

Starvation, prolonged fasting, weight loss, or food insecurity

Current smokers with T1DM

Alcoholism: Alcohol consumption may increase risk of delayed hypoglycemia, especially if on insulin or insulin secretagogues. Evening consumption of alcohol is associated with an increased risk of nocturnal and fasting hypoglycemia, especially in patients with T1DM.

Insulin secretagogues: Sulfonylureas (e.g., glyburide, glimepiride, glipizide) and glinide derivatives (repaglinide, nateglinide) stimulate insulin secretion.

Hypoglycemia is rare in diabetics not treated with insulin or insulin secretagogues.

Other antidiabetes medications such as dipeptidyl peptidase 4 (DPP-4) inhibitors, glucagon-like peptide-1 (GLP-1) agonists, and sodium-glucose contransporter-2 (SGLT-2) agents carry a lower but present risk of hypoglycemia, which may increase when combining agents from different categories.

**Geriatric Considerations**

- American Geriatric Society Beers Criteria recommend avoiding glyburide and chlorpropamide due to their prolonged half-life in older adults and risk for prolonged hypoglycemic episodes. Medications should be dosed for age and renal function.

- Individualize pharmacologic therapy in older adults to reduce the risk of hypoglycemia, avoid overtreatment, and simplify complex regimens if possible while maintaining the HgbA1C target (1)[A].

**Pediatric Considerations**

Children may not realize when they have hypoglycemia, needing increased supervision during times of higher activity. Children may have higher glycemic goals for this reason. Caregivers should be instructed in use of glucagon (1,2)[A].

**Pregnancy Considerations**

Hypoglycemia management and avoidance education should be reemphasized and blood glucose monitoring increased due to more stringent glycemic goals and increased risk in early pregnancy (1)[A].

**GENERAL PREVENTION**

- Maintain routine schedule of diet (consistent CHO intake), medication, and exercise (1)[A].

- Regular self-monitoring of blood glucose (SMBG) or continuous glucose monitoring (CGM) – Particularly helpful for asymptomatic hypoglycemia
– Use if taking insulin or secretagogue.
– Utilize ≥3 times daily testing if multiple injections of insulin, insulin pump therapy, or pregnant diabetic; frequency and timing dictated by needs and treatment goals

- Diabetes treatment and teaching programs (DTTPs), especially for high-risk type 1 patients, that teach flexible insulin therapy to enable dietary freedom
- Hypoglycemia may be decreased with use of insulin analogs, continuous SC insulin infusion (CSII) pumps, and CGM systems (1)[A].

**COMMONLY ASSOCIATED CONDITIONS**
- Autonomic neuropathy
- Neuropathies
- Cardiomyopathies

**DIAGNOSIS**

**HISTORY**
- Discuss timing of episodes, awareness, frequency, and causes (1).
- Symptoms vary considerably between individuals.
- Adrenergic symptoms
  – Hunger, trembling, pallor, sweating, shaking, pounding heart, anxiety, urinary incontinence
- Neurologic symptoms
  – Dizziness, poor concentration, drowsiness, weakness, confusion, light-headedness, slurred speech, blurred vision, double vision, unsteadiness, poor coordination
  – Hypoglycemia causes a significant deterioration in reading span and subject–verb agreement, demonstrating that language processing is impaired during moderate hypoglycemia (3).
- Behavioral symptoms
  – Tearfulness, confusion, fatigue, irritability, aggressiveness
- If altered cognition, consider hypoglycemia.

**PHYSICAL EXAM**
- General: confusion, lethargy
- HEENT: diplopia
- Coronary: tachycardia
- Neurologic: tremulousness, weakness, paresthesia, stupor, seizure, or coma
- Mental status: irritability, anxiety, inability to concentrate, or short-term memory loss
- Skin: pale, diaphoresis
- End-organ damage: microvascular, macrovascular, ophthalmologic, neurologic, renal

**DIFFERENTIAL DIAGNOSIS**
Hypoglycemia not associated with DM may be seen in:
- Chronic alcoholics and binge drinkers
- GI dysfunction causing postprandial hypoglycemia or alimentary reactive hypoglycemia
- Hormonal deficiency states (hormonal reactive hypoglycemia)
- Hypoglycemia of sepsis
- Islet cell tumors
- Factitious hypoglycemia from surreptitious injection of insulin
## DIAGNOSTIC TESTS & INTERPRETATION
- Plasma, serum, or whole-blood glucose
- SMBG and CGM are especially useful for asymptomatic hypoglycemia (2)[A].
- A hypoglycemic reading from a CGM sensor should be verified by SMBG fingerstick glucose testing prior to treatment, unless specific device is approved otherwise (1)[A].
- Low HgbA1c level may be due to chronic hypoglycemia.
- Disorders that may alter lab results
  - Conditions that affect erythrocyte turnover, such as hemolysis or blood loss, and hemoglobin variants may alter HgbA1c (1)[A].

## TREATMENT
### GENERAL MEASURES
- Glucose: pure glucose preferred; any form of CHO that contains glucose should be effective (see "Medication" section below) (1)[A].
- Glucagon should be prescribed proactively to patients at significant risk of clinically significant hypoglycemia. People in close contact with these individuals should be instructed in using an emergency glucagon kit (1)[A].
- Insulin-treated patients with hypoglycemia unawareness or an episode of clinically significant hypoglycemia should have glycemic targets raised to strictly avoid hypoglycemia (1)[A].
- α-Glucosidase inhibitors (acarbose) prevent digestion of complex CHOs; therefore, hypoglycemia must be treated with monosaccharides, such as glucose tablets.
- Patients with T1DM should use insulin analogs to reduce hypoglycemia risk (1)[A].
- Address medications (i.e., insulin, sulfonylureas, GLP-1 agonists, thiazolidinediones) that may induce hypoglycemia.
- CGM-augmented CSII with automated insulin suspension when blood glucose falls below a threshold value reduces the combined rate of severe and moderate hypoglycemia in T1DM and reduces nocturnal hypoglycemia without increasing HgbA1c levels in patients >16 years old (1,4)[A].

### MEDICATION
- Conscious patients (1)[A]:
  - Glucose (15 to 20 g) is preferred, although any form of CHO may be used.
    - Any sugar-containing food or beverage that can be rapidly absorbed: juice or nondiet soda (4 to 5 oz), candy (5 to 6 pieces of hard candy), or OTC glucose tablets (4 tablets = 16 g CHO)
    - Takes ~15 minutes for CHOs to be digested and enter bloodstream as glucose
    - Blood glucose value may correct prior to symptoms resolving.
    - “Rule of 15”: 15 to 20 g CHO (~60 to 80 calories simple CHO) repeated q15min until blood sugar is ≥70 mg/dL
  - Once sugar has normalized, a meal or snack may need to be consumed to prevent recurrence of hypoglycemia.
- Loss of consciousness at home (4)[A]:
  - Administer glucagon.
  - IM or SC in the deltoid or anterior thigh
Age <6 years and/or weight <20 to 25 kg: 0.50 mg
Age ≥6 years and/or weight >20 to 25 kg: 1 mg
May repeat dose in 15 minutes if needed

In unconscious, with emergency medical personnel present or patient hospitalized (4)[A]:
  – Give 25 g IV 50% dextrose every 5 to 10 minutes until patient awakens.
  – Then, feed orally and/or administer 5% dextrose IV at level that will maintain blood glucose >100 mg/dL.
  – Patients with hypoglycemia secondary to oral hypoglycemics should be monitored for 24 to 48 hours because hypoglycemia may recur after apparent clinical recovery.

Significant possible interactions:
  – Overtreatment may cause hyperglycemia.
  – Clearance of certain oral hypoglycemics may be prolonged in persons with renal or liver disease.

ISSUES FOR REFERRAL
Frequent or recurring episodes that do not readily respond to treatment. If anxiety and fear of hypoglycemia are uncontrolled, refer to mental health provider.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
  • A hypoglycemia prevention and management protocol should be adopted and implemented by each hospital or hospital system (1)[A].
  • Admission criteria/initial stabilization
    – Any doubt of cause
    – Expectation of prolonged hypoglycemia (e.g., caused by sulfonylurea drug)
    – Inability to drink
    – Treatment has not resulted in prompt sensory recovery.
    – Seizures, coma, or altered behavior (e.g., ataxia, disorientation, unstable motor coordination, dysphasia) secondary to documented or suspected hypoglycemia
  • Discharge criteria: Normoglycemia and risk of severe hypoglycemia are negligible.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Rest until glucose is normal. Individuals with poor cognitive function or severe hypoglycemia should have their glycemic therapy tailored to avoid significant hypoglycemia (1)[A]. Patients with hypoglycemia unawareness or unexplained severe hypoglycemia should raise their glycemic targets to avoid further hypoglycemia for several weeks to partially reverse hypoglycemia unawareness and reduce risk of additional episodes (1)[A]. Less stringent HgbA1c goals should be used in patients with history of severe hypoglycemia or frequent hypoglycemia (1)[A].

Patient Monitoring
SMBG

DIET
  • Alcohol consumption may place patients with diabetes at increased risk for delayed hypoglycemia (1)[A].
CHO sources high in protein should not be used to treat or prevent hypoglycemia (1)[A].
Fats may slow absorption of CHOs and may retard and then prolong the acute glycemic response (1)[A].
Food insecurity increases risk of hypoglycemia due to inadequate or erratic carbohydrate consumptions following administration of sulfonylureas or insulin (1)[A].

PATIENT EDUCATION
- Always have access to quick-acting CHO.
- For exercise, consider ingestion of added CHO if preexercise blood sugar <100 mg/dL or a reduced insulin dose.
- Educate patients and their relatives, close friends, teachers, and supervisors to be aware of DM diagnosis and signs/symptoms of hypoglycemia and treatment.
- Teach SMBG and self-adjustment for insulin therapy, diet control, and exercise regimen.
- Wear medical alert identification bracelet or necklace.

PROGNOSIS
Full recovery usually depends on rapidity of diagnosis and treatment.

COMPLICATIONS
- Coma, seizure, myocardial infarction, stroke (especially in elderly)
- Prolonged or severe hypoglycemia may cause permanent neurologic damage and/or cognitive impairment.
- Children with T1DM have a greater vulnerability to neurologic manifestations of hypoglycemia.

ALERT
The ACCORD trial (adults with T2DM) demonstrated that intensively lowering blood glucose below current recommendations increased the risk of death versus standard treatment strategy.

SEE ALSO
- Diabetes Mellitus, Type 1
- Algorithm: Hypoglycemia

CODES
ICD10
- E11.649 Type 2 diabetes mellitus with hypoglycemia without coma
- E10.649 Type 1 diabetes mellitus with hypoglycemia without coma
- E13.649 Oth diabetes mellitus with hypoglycemia without coma

CLINICAL PEARLS
- Best treatment includes:
  - Address hypoglycemia in every visit with patients at risk.
  - Patient education and empowerment
  - Frequent SMBG or CGM
  - Flexible insulin (or other drug) regimens
  - Individualized glycemic goals based in part on the risk of hypoglycemia
- Hypoglycemia unawareness should be recognized and addressed by less aggressive glycemic goals.
- Any form of CHO that contains glucose should be effective, such as sugar-containing food or beverage that can be rapidly absorbed:
  - Using the “rule of 15” is an easy way to teach patients to manage hypoglycemia at home.
    “Rule of 15”: 15 to 20 g CHO (~60 to 80 calories simple CHO) SMBG and repeated q15min until blood sugar is ≥70 mg/dL
HYPOGLYCEMIA, NONDIABETIC
Matthew A. Silva, PharmD, RPh, BCPS • Pablo I. Hernandez Itriago, MD, MHCM, FAAFP

BASICS
DESCRIPTION
- Hypoglycemia defined by the Whipple triad
  - Low plasma glucose level (≤60 mg/dL) with hypoglycemic symptoms that are relieved when glucose is corrected
  - Occurs commonly in patients with diabetes receiving sulfonylurea or insulins; less commonly in patients without diabetes
- Post-prandial or reactive hypoglycemia occurs in response to a meal, drugs, herbal substances, or nutrients and may occur 2 to 3 hours postprandially or later. This is non-congenital, beta-islet dysregulation with or without hyperplasia and insulin secretion.
  - Symptoms are generally observed with serum glucose ≤60 mg/dL, lower in patients with hypoglycemic unawareness.
  - Also seen after GI surgery (in association with dumping syndrome in some patients)
- Spontaneous (fasting) hypoglycemia may be associated with primary conditions including hypopituitarism, Addison disease, myxedema, or disorders related to hepatic dysfunction or renal failure (1,2).
  - If hypoglycemia presents as a primary disorder, consider hyperinsulinism and extrapancreatic tumors.

EPIDEMIOLOGY
Incidence
- True incidence is unknown.
- 0.5–8.6% of hospitalized patients ≥65 years (3,4,5)
  - Asymptomatic in 25% of cases

Prevalence
True prevalence is unknown:
- Predominant age: older adult
- Predominant sex: female > male

ETIOLOGY AND PATHOPHYSIOLOGY
- Reactive, postprandial
  - Alimentary hyperinsulinism
  - Meals high in refined carbohydrate
  - Certain nutrients, including fructose, galactose, leucine
  - Glucose intolerance (prediabetes)
  - GI surgery, especially gastric bypass
  - Idiopathic (unknown cause)
- Spontaneous
  - Fasting
– Alcohol or prescription medication–associated (6) (insulin, sulfonylureas, thiazolidinediones, incretin mimetics, DPP-IV inhibitors, β-blockers, salicylates, quinine, hydroxychloroquine, fluoroquinolones, doxycycline, sertraline, disopyramide, pentamidine, gabapentin, tramadol)
– Nonprescription over-the-counter (OTC) agents, including performance-enhancing agents. Adulterated versions of phosphodiesterase inhibitors and performance-enhancing agents are routinely imported and may contain sulfonylureas and other hypoglycemic agents.
– Consider medication errors as a source of unexplained hypoglycemia even in patients without diabetes.
– Consider accidental, surreptitious, or malicious use of insulin or oral hypoglycemics.
– Natural medicines or herbs (bitter melon, caffeine, cassia cinnamon, chromium, fenugreek, ginseng, guarana, mate, stevia, vanadium)
– Postsurgical (e.g., bariatric surgery, gastrectomy, Roux-en-Y) hypoglycemia/dumping syndrome
– Islet cell hyperplasia or tumor (insulinoma)
– Extrapancreatic insulin-secreting tumor
– Autoimmune hypoglycemia (Hirata disease)
– Hepatic disease
– Glucagon deficiency
– Adrenal insufficiency
– Catecholamine deficiency
– Hypopituitarism
– Hypothyroidism
– Eating disorders
– Exercise
– Fever
– Pregnancy
– Renal glycosuria
– Large tumors
– Ketotic hypoglycemia of childhood
– Enzyme deficiencies or defects
– Severe malnutrition
– Sepsis
– Total parenteral nutrition therapy
– Hemodialysis

Genetics
Some aspects may involve genetics (e.g., hereditary fructose intolerance).

RISK FACTORS
Refer to “Etiology and Pathophysiology.”

GENERAL PREVENTION
● Follow dietary and exercise guidelines.
● Patient recognition of early symptoms and knowledge of corrective action

Pediatric Considerations
● Usually divided into two syndromes
– Transient neonatal hypoglycemia
– Hypoglycemia of infancy and childhood
• Screening infants for hypoglycemia is appropriate when pregnancy was complicated by maternal diabetes.
• Cases of hypoglycemia observed in children taking propranolol for infantile hemangioma
• Associated with indomethacin when treating patent ductus arteriosus

Geriatric Considerations
• More likely to have underlying disorders or be caused by medications
• Iatrogenic hypoglycemia is common in the hospitalized elderly with renal insufficiency.

COMMONLY ASSOCIATED CONDITIONS
• Severe liver disease; alcoholism
• Addison disease; adrenocortical insufficiency
• Myxedema
• Malnutrition (patients with renal failure)
• GI surgery
• Panhypopituitarism
• Insulinoma

DIAGNOSIS

HISTORY
• CNS (neuroglycopenic) symptoms predominate with gradual glucose reduction:
  – Headache
  – Confusion
  – Light-headedness
  – Fatigue and weakness
  – Visual disturbances
  – Changes in personality
• Adrenergic symptoms: more prominent in acute drop in glucose
  – Anxiety
  – Tremulousness
  – Dizziness
  – Diaphoresis
  – Warmth/flushing
  – Heart palpitations
• GI symptoms
  – Hunger
  – Nausea
  – Belching

PHYSICAL EXAM
• CNS (neuroglycopenic) symptoms predominate with gradual glucose reduction:
  – Convulsions
  – Coma
  – Hypotension
Adrenergic symptoms: more prominent in acute drop in glucose
  – Tremulousness
  – Diaphoresis
  – Warmth/flushing
  – Heart palpitations

DIFFERENTIAL DIAGNOSIS
CNS disorders
  – Psychogenic
  – Pseudohypoglycemia: symptoms of hypoglycemia or self-diagnosis in patients in whom low blood glucose may not be detectable and may be impossible to convince that they do not suffer from hypoglycemia after all tests are found to be normal

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
  – Blood glucose ≤45 mg/dL (≤2.5 mmol/L) when symptomatic followed by symptom resolution with feeding (2)[C]
  – Plasma glucose overnight fasting: ≤60 mg/dL (≤3.33 mmol/L); confirm on ≥2 occasions (2)[C].
  – Plasma glucose 72-hour fasting: ≤45 mg/dL (≤2.5 mmol/L) for females; ≤55 mg/dL (≤3.05 mmol/L) for males; fasting may be ended when Whipple triad is achieved or hypoglycemia is demonstrated (2)[C].
  – Abdominal CT to rule out abdominal tumor

Follow-Up Tests & Special Considerations
  – Misinterpretation of glucose tolerance tests may lead to misdiagnosis of hypoglycemia; ≥1/3 of normal patients have hypoglycemia, with or without symptoms, during the 4-hour glucose tolerance test. These patients may be at future risk for type 2 diabetes.
  – C-peptide measurement (2)[C]
  – Check liver studies, serum insulin, adrenocorticotropic hormone (ACTH), and cortisol. Serum insulin should be suppressed when glucose is <60 mg/dL.
  – Serum β-hydroxybutyrate (2)[C]
  – Insulin radioimmunoassay: Elevated insulin levels suggest islet cell hyperplasia or tumor.
  – Drugs that may alter lab results: Many drugs can affect glucose levels; review drugs individually and refer to drug or laboratory reference.

Diagnostic Procedures/Other
  – For definitive diagnosis, patient should have
    – Documented low glucose levels
    – Symptoms when glucose levels are low
    – Evidence that symptoms are relieved specifically by ingestion of sugar or other food
    – Identification of the specific type of hypoglycemia
  – Serum β-hydroxybutyrate <2.7 mg/dL in the presence of high-serum insulin, C-peptide, and low-serum glucose suggests excessive insulin production (2)[C].

TREATMENT
GENERAL MEASURES
- Outpatient except for severe cases; may also be inpatient for testing
- Oral carbohydrate for alert patient without drug overdose (2 to 3 tbsp of sugar in glass of water or fruit juice, 1 to 2 cups of milk, piece of fruit, or several soda crackers)
- If unable to swallow: Use glucagon IM or SC.
- If caused by medication or nutrients: Avoid or control causative agents.
- If triggered by meals: Try high-protein diet with carbohydrate restriction.
- Nonhypoglycemic hypoglycemia or pseudohypoglycemia
  - Many patients (often women ages 20 to 45 years) present with diagnosis of reactive or post-prandial hypoglycemia (self-diagnosed or misinterpretation of tests).
  - Symptoms may pertain to chronic fatigue and somatic complaints (stress often plays a role in these symptoms).
  - Management difficult; listening is important. Try 120-g carbohydrate diet.
  - Counseling may be useful for stress and other problems.

MEDICATION
- Once diagnosis is established, begin therapy appropriate for underlying disorder.
- If unable to swallow: glucagon 1 mg (1 unit) IM or SC. If no response, give IV bolus of 25 to 50 g of 50% glucose solution followed by continuous infusion until patient able to take by mouth.
- Postsurgical gastrectomy patients unresponsive to dietary changes may benefit from propantheline, psyllium, fiber, or oat bran to delay gastric emptying.

SURGERY/OTHER PROCEDURES
If islet cell tumor (insulinoma) or other insulin-secreting tumor, surgery is treatment of choice; if inoperable, diazoxide may relieve symptoms (1)\[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Hypoglycemia unresponsive to oral intake

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Exercise routine or daily activity may need to be reevaluated and readjusted.
- Patients with recurrent hypoglycemia should have glucose source at hand for immediate ingestion during symptoms.

Patient Monitoring
- Depends on type and severity of symptoms and treatment of underlying cause
- Hypoglycemia from sulfonylureas can last for hours to days depending on half-life and renal function.

DIET
- High protein, high fiber, complex carbohydrates from multigrain, and whole foods in moderation
- Frequent small feedings (six daily)
- Avoid fasting
PATIENT EDUCATION
- Dietary instruction
- Counseling for stress, if appropriate
- Recognition of early symptoms of hypoglycemia and how to take corrective action

PROGNOSIS
Favorable, with appropriate treatment

COMPLICATIONS
- Insulinoma: If tumor identified and removed, some surgical risk is involved.
- Organic brain syndrome: may occur with extensive, prolonged hypoglycemia

REFERENCES

ADDITIONAL READING

SEE ALSO
- Hypoglycemia, Diabetic; Insulinoma
- Algorithm: Hypoglycemia

CODES
ICD10
- E16.2 Hypoglycemia, unspecified
- E16.1 Other hypoglycemia
- P70.4 Other neonatal hypoglycemia
CLINICAL PEARLS

- Symptoms coincide with low blood glucose levels and resolve with PO/IV glucose or glucagon.
- Avoid known agents/nutrients that trigger hypoglycemia.
- Treat underlying cause.
HYPOKALEMIA
James Auteri Ferguson, MD, MPH, CPH • Jason Chao, MD, MS • Abirami Raveendran, MD, MSc

BASICS
DESCRIPTION
Hypokalemia is defined as a serum potassium concentration <3.5 mEq/L (normal range, 3.5 to 5.0 mEq/L).
- Mild hypokalemia (serum potassium 3.0 to 3.5 mEq/L)
- Moderate hypokalemia (serum potassium 2.5 to 3.0 mEq/L)
- Severe hypokalemia (serum potassium <2.5 mEq/L)

EPIDEMIOLOGY
Predominant sex: male = female

Incidence
- Electrolyte abnormality is commonly encountered in clinical practice and in the elderly.
- Found in >20% of hospitalized patients (when defined as potassium <3.6 mEq/L)
- Higher incidence (5–20%) in individuals with eating disorders
- >10% of inpatients with alcoholism
- Higher incidence in patients with AIDS
- Higher incidence in patients receiving diuretics
- 12–18% in patients with CKD
- Associated risk after bariatric surgery

ETIOLOGY AND PATHOPHYSIOLOGY
Most common causes:
- Decreased intake: deficient diet in alcoholics and elderly; anorexia nervosa
- GI loss: vomiting, diarrhea, nasogastric tubes, laxative abuse, fistulas, villous adenoma, ureterosigmoidostomy, malabsorption, chemotherapy, radiation enteropathy, bulimia
- Intracellular shift of potassium: metabolic alkalosis, insulin excess, β-adrenergic catecholamine excess (acute stress, β2-agonists), hypokalemic periodic paralysis, intoxications (theophylline, caffeine, barium, toluene), refeeding syndrome (1)[C]
- Renal potassium loss
  - Drugs: diuretics (especially loop and thiazides), amphotericin B, aminoglycosides
  - Mineralocorticoid excess states: primary hyperaldosteronism; secondary hyperaldosteronism (congestive heart failure [CHF], cirrhosis, nephrotic syndrome, malignant hypertension, renin-producing tumors); renovascular hypertension; Bartter syndrome; Gitelman syndrome; congenital adrenogenital syndromes; exogenous mineralocorticoids (glycyrrhizic acid in licorice, carbenoxolone, steroids in nasal sprays); Liddle syndrome; vasculitis
  - Osmotic diuresis (e.g., poorly controlled diabetes)
  - Renal tubular acidosis (type I and II)
  - Magnesium depletion
Glucocorticoid excess states: Cushing syndrome, exogenous steroids, ectopic adrenocorticotropic hormone production, 11-β-hydroxysteroid dehydrogenase deficiency, refeeding syndrome

Genetics
Some rare, familial disorders can cause hypokalemia.
- Familial hypokalemic periodic paralysis: hypokalemia after a high-carbohydrate or high-sodium meal or after exercise
- Congenital adrenogenital syndromes
- Liddle syndrome: increases K+ secretion
- Familial interstitial nephritis

GENERAL PREVENTION
When initiating a diuretic, especially loop and thiazide diuretics, advise patients to increase their dietary potassium intake (see “Diet”).

COMMONLY ASSOCIATED CONDITIONS
- Acute GI illnesses with severe vomiting or diarrhea
- Increased risk of cardiac arrhythmias; atrial fibrillation
- Hypokalemia is a predictor of development of severe alcohol withdrawal syndrome.

DIAGNOSIS
- Patients with hypokalemia often have no symptoms, especially if the hypokalemia is mild (serum potassium 3.0 to 3.5 mEq/L).
- Neuromuscular (most prominent manifestations)
  - Easy fatigability, cramping, myalgias
  - Skeletal muscle weakness (proximal > distal muscles, lower limbs > upper limbs) may range from mild weakness to total paralysis, including respiratory muscles; it may lead to rhabdomyolysis and/or respiratory acidosis/arrest in severe cases.
  - Smooth muscle involvement may lead to GI hypomotility, producing ileus and constipation.
- Cardiovascular
  - Ventricular arrhythmias; higher risk if underlying CHF, left ventricular failure (LVF), cardiac ischemia
  - Increased risk of atrial fibrillation
  - Hypotension
  - Cardiac arrest
- Renal: polyuria, polydipsia, nocturia owing to impaired ability to concentrate, myoglobinuria
- Metabolic: hyperglycemia, alkalosis

HISTORY
Muscle weakness, hypotension, vomiting, diarrhea, polyuria, polydipsia

PHYSICAL EXAM
Decreased skin turgor in dehydration, hypotension, orthostasis, pulmonary congestion/rales, peripheral edema in heart failure

DIFFERENTIAL DIAGNOSIS
Spurious hypokalemia occurs when blood with high WBC count (>100,000/mm³) is allowed to stand at room temperature (WBCs extract potassium from plasma).

**Thyrotoxicosis**

**DIAGNOSTIC TESTS & INTERPRETATION**

- Serum potassium <3.5 mEq/L (<3.5 mmol/L)
- Disorders that may alter lab results: leukemia and other conditions with high WBCs

**Initial Tests (lab, imaging)**

- ECG
- If source of potassium loss not likely to be medications or GI tract: serum electrolytes, urinary potassium
- Calculate plasma anion gap (anion gap = Na − [Cl + HCO₃⁻]); normal values, 12 ± 4 mEq/L. Must correct calculated anion gap for hypoalbuminemia. Increase calculated anion gap by 2.5 mEq/L for each 1 g/dL decrease in albumin <4 g/dL.
- CT scan of adrenal glands if there is evidence of mineralocorticoid excess

**Follow-Up Tests & Special Considerations**

- If excessive renal potassium loss (>20 mEq/day) and hypertension, plasma renin and aldosterone levels should be determined to differentiate adrenal from nonadrenal causes of hyperaldosteronism. If hypertension is absent and the patient is acidotic, renal tubular acidosis should be considered.
- In severe hypokalemia, rhabdomyolosis may result.
- Hypokalemia increases the myocyte resting potential, which increases the refractory period; this can lead to cardiac arrhythmias.

**Test Interpretation**

- If hypertension is absent and serum pH is normal to alkalotic
  - High urine chloride (>10 mEq/day [>10 mmol/day])—diuretics or Bartter and Gitelman syndromes
  - Low urine chloride (<10 mEq/day [<10 mmol/day])—GI losses likely
- ECG
  - Flattening or inversion of T waves
  - Increased prominence of U waves (small, positive deflection after T wave, best seen in V₂ and V₃)
  - Depression of ST segment
  - Ventricular ectopia

**TREATMENT**

**GENERAL MEASURES**

- Underlying cause of hypokalemia should be identified.
- For asymptomatic patients treated with oral replacement, outpatient follow-up is sufficient.
- Patients with cardiac manifestations require IV replacement with cardiac monitoring in an intensive care setting.

**MEDICATION**
Nonemergent conditions (serum potassium >2.5 mEq/L [>2.5 mmol/L], no cardiac manifestations)
- Oral therapy preferred: 40 to 120 mEq/day (40 to 120 mmol/day) in divided doses usually is adequate.
- IV potassium should be given only when oral administration is not feasible (e.g., vomiting, postoperative state). Rate should not exceed 10 mEq/hr, and concentration should not exceed 40 mEq/L. Up to 40 mEq in 100 mL over 1 hour can be given safely through a central venous line. The patient’s cardiac rhythm should be closely monitored.
- Potassium chloride is suitable for all forms of hypokalemia.
- Other potassium salts may be indicated if a coexisting disorder is present: potassium bicarbonate or bicarbonate precursor (gluconate, acetate, or citrate) in metabolic acidosis or phosphate in phosphate deficiency (2)[C].

Emergent situations (serum potassium <2.5 mEq/L [<2.5 mmol/L], arrhythmias), IV replacement: Rate of administration should not exceed 20 mEq/hr (20 mmol/hr); maximum recommended concentration, 60 mEq/L (60 mmol/L) of saline for peripheral administration; administration through central venous lines preferred for rates >20 mEq/hr
- Check serum magnesium and replace, if needed; cannot adequately replace potassium in a setting of low magnesium

Precautions
- Any form of potassium replacement carries the risk of hyperkalemia.
- Serum potassium should be checked more frequently in groups at higher risk: the elderly, diabetic patients, and patients with renal insufficiency.
- Patients receiving digitalis and patients with diabetic ketoacidosis in whom intracellular shift in potassium is expected after insulin therapy is initiated must have more aggressive replacement.

Significant possible interactions: Concomitant administration of potassium-sparing diuretics (spironolactone, triamterene, amiloride, ACE inhibitors) magnifies risk of hyperkalemia.

Geriatric Considerations
May need to correct magnesium depletion

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Patients receiving IV therapy should have cardiac monitoring and serum potassium level checked frequently (q4–6h).
- Patients requiring potassium supplements should have serum potassium studied at intervals and magnesium level dictated by clinical judgment and patient compliance (3)[C].

DIET
In patients with mild hypokalemia (potassium, 3.0 to 3.5 mEq/L [3.0 to 3.5 mmol/L]) not caused by GI losses, dietary supplementation may be sufficient; potassium-rich foods include oranges, bananas, cantaloupes, prunes, raisins, dried beans, dried apricots, and squash.

PATIENT EDUCATION
Instructions for appropriate diet
If potassium supplementation is necessary, stress the need for compliance.

PROGNOSIS
- Associated with higher morbidity and mortality because of cardiac arrhythmias
- Ease of correction of hypokalemia and need for prolonged treatment rest on the primary cause; if it can be eliminated (e.g., resolution of diarrhea, discontinuation of diuretics, removal of adrenal tumor), hypokalemia can be expected to resolve, and no further treatment is indicated.

COMPLICATIONS
- Hyperkalemia can occur during the course of treatment.
- Increased risk of digoxin toxicity
- Increased risk of atrial fibrillation (4)[B]

REFERENCES

ADDITIONAL READING

SEE ALSO
- Hyperkalemia
- Algorithm: Hypokalemia

CODES
ICD10
E87.6 Hypokalemia
**CLINICAL PEARLS**

- In patients without heart disease, a mildly low potassium level will rarely cause cardiac disturbances. In an otherwise healthy patient, gentle repletion using oral potassium or an increase in potassium-rich foods should be adequate.
- In patients with cardiac ischemia, heart failure, or left ventricular hypertrophy, even mild to moderate hypokalemia can cause arrhythmias. These patients should receive potassium repletion as well as cardiac monitoring.
- To safely prevent hypokalemia in diabetic and renal insufficiency patients, ensure adequate dietary potassium intake with foods rich in potassium, including spinach, tomatoes, broccoli, squash, potatoes, bananas, cantaloupe, and oranges. Avoid potassium-wasting diuretics, if possible.
- Uncorrected hypomagnesemia can hinder the correction of hypokalemia. Check magnesium levels and replete as necessary.
- Hypokalemia in an otherwise healthy young woman should prompt evaluation for bulimia nervosa.
HYPONATREMIA
Caitlin E. Jones, MD ● Patricia Martinez Quinones, MD ● Cassandra Q. White, MD, FACS

BASICS

DESCRIPTION
• Hyponatremia is a plasma sodium (Na⁺) concentration of ≤135 mEq/L.
• Hyponatremia itself does not provide information about the “total body water (TBW)” state of the patient. Patients with hyponatremia may be hypervolemic, hypovolemic, or euvolemic.
• System(s) affected: endocrine/metabolic, renal, cardiovascular, central nervous system (CNS)

EPIDEMIOLOGY

Incidence
• Most common electrolyte disorder seen in the general hospital population
• Predominant age: all ages
• Predominant sex: male = female

Prevalence
• 2.5% of hospitalized patients
• 20–30% in hospitalized patients (1)
• 7.7% outpatients (1)

Geriatric Considerations
The elderly have lower TBW, a decreased thirst mechanism, and decreased urinary concentrating ability; their kidneys are less responsive to antidiuretic hormone (ADH), and they show decreased renal mass, renal blood flow, and glomerular filtration rate, putting them at higher risk for hyponatremia. Presenting symptoms may be frequent falls and gait disturbances.

Pediatric Considerations
Children <16 years of age have less intracranial space and are at increased risk of brain herniation from cerebral edema.

ETIOLOGY AND PATHOPHYSIOLOGY
• Assess serum osmolality and volume status to determine etiology. The etiology directs the management.
• Hypertonic hyponatremia: serum osmolarity (Osm) >295 mOsm
  – Shift of water from intracellular fluid (ICF) to extracellular fluid (ECF), resulting in dilution
    – Unchanged TBW and Na⁺
    – Causes: hyperglycemia, mannitol, sorbitol, radiologic contrast
• Isotonic hyponatremia (“pseudohyponatremia”): serum Osm 275 to 295 mOsm
  – Excessive osmoles leading to dilution
  – Unchanged TBW and Na⁺
  – Causes: hyperlipidemia, hyperproteinemia (e.g., multiple myeloma), laboratory artifact, irrigant solutions
Hypotonic hyponatremia: serum Osm <275 mOsm
- Subdivided by volume status into hypovolemic, euvoletic, or hypervolemic
  - Hypovolemic hyponatremia: subtype of hypotonic hyponatremia with decreased TBW and Na⁺
    - Signs include orthostatic hypotension, decreased skin turgor, dry mucous membranes.
    - Urine Na⁺ <20 mmol/L; indicates extrarenal loss
      - Causes include GI loss (vomiting, diarrhea), third spacing (pancreatitis, peritonitis, burns, rhabdomyolysis), skin loss (burns, cystic fibrosis, sweating), and heat-related illnesses.
    - Urine Na⁺ >20 mmol/L; indicates renal loss
      - Causes include cerebral salt-wasting syndrome, adrenal insufficiency, diuretics, and osmotic diuresis.
- Euvolemic hyponatremia: most common subtype of hypotonic hyponatremia with increased TBW and normal Na⁺
  - Signs include a nonedematous state.
  - Urine Osm >100 mOsm/kg
    - Causes include syndrome of inappropriate antidiuretic hormone (SIADH), hypothyroidism, adrenal insufficiency, medications (e.g., thiazide diuretics, loop diuretics, carbamazepine, clofibrate, cyclosporine, levetiracetam, oxcarbazepine, SSRIs, TCAs, vincristine).
  - Urine Osm <100 mOsm/kg
    - Causes include primary polydipsia, beer potomania (massive consumption of beer, which is poor in solutes and electrolytes), and exercise-induced.
- Hypervolemic hyponatremia: subtype of hypotonic hyponatremia with increased TBW and Na⁺
  - Signs include edematous state.
  - Urine Na⁺ <20 mmol/L
    - Causes include congestive heart failure (CHF), cirrhosis, nephrotic syndrome, hypoalbuminemia, psychogenic polydipsia.
  - Urine Na⁺ >20 mmol/L
    - Causes include CHF, liver cirrhosis, nephrotic syndrome, and chronic renal failure.

Genetics
- Polymorphisms have been demonstrated.
- Mutations have been associated with nephrogenic syndrome of inappropriate antidiuresis (NSIAD; SIADH).

GENERAL PREVENTION
Depends on underlying etiology

COMMONLY ASSOCIATED CONDITIONS
- Hypothyroidism
- Hypopituitarism
- Cirrhosis
- CHF
- Nephrotic syndrome
- Adrenocortical hormone deficiency
- HIV patients
DIAGNOSIS

Symptoms related to the rate of fall in serum Na\(^+\), onset and degree of hyponatremia (2)
Acute (≤48 hours): no time for full adaptation, more likely to present with moderate or severe symptoms
Chronic: develops gradually, organ systems adapt to Na\(^+\) concentration, associated with minimal symptoms
Mild (serum Na\(^+\) 130 to 135 mEq/L): usually asymptomatic, fatigue, loss of appetite
Moderate (serum Na\(^+\) 120 to 130 mEq/L): nausea, vomiting, lethargy
Severe (serum Na\(^+\) 115 to 120 mEq/L): headache, lethargy, restlessness, disorientation
Severe/rapid decrease in serum Na\(^+\) can cause seizures, coma, brain herniation, respiratory arrest, and may be fatal.
Other signs and symptoms: weakness, muscle cramps, anorexia, hiccups, depressed deep tendon reflexes, hypothermia, positive Babinski responses, cranial nerve palsies, orthostatic hypotension

ALERT

Low Na\(^+\) creates an osmotic gradient between plasma and cells, resulting in fluid shift into cells. This causes cerebral edema and increased intracranial pressure; eventually, this can lead to hyponatremic encephalopathy and brain herniation.

HISTORY

Symptoms include headache, nausea, vomiting, muscle cramps.
Can progress to lethargy or restlessness and disorientation

PHYSICAL EXAM

Volume status: skin turgor, jugular venous pressure, heart rate, orthostatic blood pressure measurement
Evaluate for underlying illness: signs of CHF, cirrhosis, hypothyroidism.
Decreased reflexes may be seen.

DIFFERENTIAL DIAGNOSIS
See “Etiology and Pathophysiology.”

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Comprehensive metabolic profile (BUN, creatinine, glucose, electrolytes, liver function studies, etc.)
• Thyroid-stimulating hormone (TSH)
• Lipid panel
• Serum osmolality
• Urine Na⁺ and osmolality
• Chest x-ray to rule out pulmonary pathology if SIADH is diagnosed

Follow-Up Tests & Special Considerations
CT scan of head if pituitary problem is suspected or if SIADH from CNS problem is suspected

TREATMENT

GENERAL MEASURES
• Assess all medications patient is taking.
• Institute seizure precautions.
• Institute fluid restriction.
• Indications for 3% hypertonic saline versus normal saline solution: acute hyponatremia, symptomatic hyponatremia, association with intracranial pathology already at risk for cerebral edema

MEDICATION

ALERT
Rapid correction of severe symptomatic hyponatremia has been associated with central pontine myelinolysis, a neurologic disorder of loss of myelin and supportive structures in pons and occasionally in other areas of the brain (3). This results in irreversible injury. Symptoms are apparent 2 to 6 days after injury and include seizure, coma, spastic paraparesis, dysarthria, and dysphagia. Patients at increased risk are those with Na⁺ <105, alcoholism, hypokalemia, malnutrition, and advanced liver disease liver transplant recipients. MRI is not required for diagnosis because it may not be positive until 4 weeks after symptom onset.

• Treatment is tailored to etiology, degree of hyponatremia, onset, and symptomatology.
• Some general principles apply:
  – Expected change in serum Na⁺ with selected infusate: ΔNa = [(infusate Na⁺ + infusate K⁺-serum Na⁺) / (TBW + 1)]
  – TBW = a coefficient × weight (kg) as in the following table:

<table>
<thead>
<tr>
<th>Total Body Water</th>
<th></th>
</tr>
</thead>
</table>
| Children                | 0.6 × weight
| Women                   | 0.5 × weight
| Men                     | 0.6 × weight
| Elderly women           | 0.45 × weight
| Elderly men             | 0.5 × weight |

– Formula to determine correction available at http://www.medcalc.com/sodium.html
• Asymptomatic, euvolemic patients can be treated with fluid restriction; etiology must be addressed.
• For severely hyponatremic/symptomatic patients, administer 3% hypertonic saline, 2 mL/kg up
to 100 mL, over a 20-minute period. Check serum Na\(^+\) levels after infusion. Repeat as necessary until a 5 mmol/L increase in serum Na\(^+\) is seen. Admit to ICU and check Na\(^+\) every 2 hours.

- If symptoms improve after a 5 mmol/L increase, discontinue the hypertonic saline and switch to 0.9% isotonic saline solution. Increase serum Na\(^+\) with a limit of 10 mmol/L during the first 24 hours and then 8 mmol/L every day afterward until serum Na\(^+\) is 130 mmol/L.
- If symptoms do not improve after a 5 mmol/L increase, continue the hypertonic saline infusion until 1 mmol/L/hr increase in serum Na\(^+\) is achieved. Discontinue infusion if symptoms improve, serum Na\(^+\) increases by 10 mmol/L, or serum Na\(^+\) is 130 mmol/L.

For mild to moderate hyponatremia, use isotonic saline solution (0.9%). For moderate to severe hyponatremia, consider specialist consultation for use of hypertonic saline (3%) via central venous access at a rate of 1 to 2 mL/kg/hr; increasing serum Na\(^+\) levels by 0.5 mmol/L/hr and monitoring frequently the plasma Na\(^+\) level (approximately every 2 hours).

- In patients with severe hyponatremia (euvoletic and hypervolemic state) who do not respond to the aforementioned approach, consider the use of vasopressin V2-receptor antagonists, such as tolvaptan or conivaptan (4)[A].

- Treat underlying etiology.
- Chronic hyponatremia resulting from SIADH (5): demeclocycline (inhibits ADH action at the collecting duct) if fluid restriction alone is not effective
  - Contraindications: drug allergy, pregnancy, children <8 years old; caution in renal and hepatic disease
  - In doses of 600 to 1,200 mg/day, the drug produces nephrogenic diabetes insipidus.
  - Significant possible interactions: oral anticoagulants, oral contraceptives, penicillin
  - In case of overcorrection, relower Na\(^+\) concentration. Begin with infusion of 3 mL/kg of 5% dextrose in water over 1 hour. Repeat Na\(^+\) measurement. Be cautious, dextrose infusion rates >250 to 300 mL/hr can cause significant hyperglycemia in both diabetic and nondiabetic patients and may lead to osmotic diuresis and subsequent free water loss with increased serum Na\(^+\) concentration. Consider 2 to 4 μg IV desmopressin every 8 hours to prevent overcorrection.

**ALERT**

Caution: If severe, consider hypertonic saline (3% Na\(^+\) chloride) with central line access, exercise extreme caution, and monitor serum Na\(^+\) as frequently as every 1 to 2 hours.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Admission is mandatory if the patient has acute hyponatremia or is symptomatic; acute hyponatremia (developing over <48 hours) increases the risk of cerebral edema.
- Admission is advised if patient is asymptomatic and has a serum Na\(^+\) <125 mEq/dL.

**ONGOING CARE**

**DIET**

- Euvolemic hyponatremia: Restrict water to 1 L/day.
Hypervolemic hyponatremia: water and Na\textsuperscript{+} restriction

PROGNOSIS
- In hospitalized patients, hyponatremia is associated with an elevated risk of adverse clinical outcomes and higher mortality (1)[B].
- Recently, in community-dwelling, middle-aged, and elderly adults, mild hyponatremia has been shown to be an independent predictor of death.
- Associated with poor prognosis in patients with acute pulmonary embolism
- Associated with poor prognosis in patients with liver cirrhosis and those waiting for liver transplant; it is associated with significant postoperative risk and short-term graft loss.

COMPLICATIONS
- Occult tumor may be present if SIADH is identified.
- Hypervolemia if isotonic saline solution is used
- Osmotic demyelination (central pontine and extrapontine irreversible myelinolysis) (1)
- Hyponatremia is the cause of 30% new-onset seizures in intensive care settings.
- Can cause hyponatremic encephalopathy and brain herniation if severe and untreated, especially in young women and children (2)
- Chronic hyponatremia is associated with increased risk of osteoporosis, attention deficit, gait disturbances, falls, and fractures.

Algorithm: Hyponatremia

CODES
ICD10
E87.1 Hypo-osmolality and hyponatremia

CLINICAL PEARLS

- Assess all medications patient is taking because many are associated with hyponatremia.
- Alcohol-dependent individuals with vitamin deficiencies, elderly women taking thiazide diuretics, and people with hypokalemia or burns are at increased risk of central pontine myelinolysis from too rapid correction of hyponatremia. Chronic hyponatremia is also a risk factor.
- Bronchogenic carcinoma and pancreatic, duodenal, and prostate cancer, as well as thymoma, lymphoma, and mesothelioma, are neoplastic diseases associated with SIADH.
- Formulas have been developed (Adrogue and Madias) for safe correction of hyponatremia and are available online (see http://www.medcalc.com/sodium.html).
HYPOPARATHYROIDISM
Cherry Onaiwu, MD, MS ● Luay Sarsam, MD ● Carrie Valenta, MD, FACP, FHM

BASICS

DESCRIPTION
- Deficient or absent secretion of parathyroid hormone (PTH), a major hormone regulator of serum calcium and phosphorus levels in the body (1)
- Acute hypoparathyroidism: tetany that is mild (muscle cramps, perioral numbness, paresthesias of hands and feet) or severe (carpopedal spasm, laryngospasm, heart failure, seizures, stridor)
- Chronic: often asymptomatic; lethargy, anxiety/depression, urolithiasis and renal impairment, dementia, blurry vision from cataracts or keratoconjunctivitis, parkinsonism or other movement disorders, mental retardation, dental abnormalities, and dry, puffy, coarse skin
- System(s) affected: endocrine/metabolic, musculoskeletal, nervous, ophthalmologic, renal

Pediatric Considerations
- May occur in premature infants
- Neonates born to hypercalcemic mothers may experience suppression of developing parathyroid glands.
- Congenital absence of parathyroids
- May appear later in childhood as autoimmune

Geriatric Considerations
Hypocalcemia is fairly common in elderly, however, rarely secondary to hypoparathyroidism.

Pregnancy Considerations
- Use of magnesium as a tocolytic may induce functional hypoparathyroidism.
- For women with hypoparathyroidism, calcitriol requirements decrease during lactation.

EPIDEMIOLOGY
More common in women; affects all ages

Incidence
Most common after surgical procedure of the anterior neck (75% of all cases). Transient hyperparathyroidism is seen after 6.9–46% of thyroidectomies, whereas permanent hypoparathyroidism, 0.9–1.6% at experienced centers.

Prevalence
- Affects 24 to 37/100,000 persons per year (1)
- Autosomal dominant hypocalcemia with hypercalciuria (ADHH): 1/70,000 typically in infancy with hypocalcemic seizures

ETIOLOGY AND PATHOPHYSIOLOGY
- PTH aids in regulating calcium homeostasis:
  - Mobilizes calcium and phosphorus from bone stores
  - Increases calcium absorption from the intestine by stimulating formation of 1,25-dihydroxy
vitamin D
- Stimulates reabsorption of calcium in the distal convoluted tubule and phosphate excretion in proximal tubule

- Reduced or absent PTH action results in hypocalcemia, hyperphosphatemia, and hypercalciuria.

- Acquired hypoparathyroidism
  - Surgical: removal or damage to parathyroid glands or their blood supply; thyroid, parathyroid, or neck surgery for head and neck cancers (2)
  - Autoimmune: isolated or combined with other endocrine deficiencies in polyglandular autoimmune (PGA) syndrome
  - Deposition of heavy metals in gland: copper (Wilson disease) or iron (hemochromatosis, thalassemias), radiation-induced destruction, and metastatic infiltration
  - Functional hypoparathyroidism: may result from hypomagnesemia or hypermagnesemia because magnesium is crucial for PTH secretion and activation of the PTH receptor
  - Congenital
    - Calcium-sensing receptor (CaSR) abnormalities: hypocalcemia with hypercalciuria
    - HDR or Barakat syndrome: deafness, renal dysplasia
    - Familial: mutations of the TBCE gene; abnormal PTH secretions
    - 22q11.2 deletion syndrome

- Autoimmune: genetic gain-of-function mutation in CaSR
- Infiltrative: metastatic carcinoma, hemochromatosis, Wilson disease, granulomas
- Hypo- (patients with alcohol use disorder) or hypermagnesemia: chronic iron overloads

Genetics
- X-linked or in autosomal recessive mutations in the transcription factor glial cell missing B (GCMB)
- Mutations in transcription factors or regulators of parathyroid gland development
  - Component of a larger genetic syndrome (APS-1 or DiGeorge syndrome) or in isolation (X-linked hypoparathyroidism) (3)
  - May be autosomal dominant (DiGeorge), autosomal recessive (APS-1), or X-linked recessive (X-linked hypoparathyroidism) (3)
  - Congenital syndromes
    - 22q11.2 deletion syndrome, familial hypomagnesemia, hypoparathyroidism with lymphedema (3)
    - Hypoparathyroidism with sensorineural deafness
    - ADHH: mutations gain-of-function of the CaSR gene suppressing the parathyroid gland, without elevation of PTH
  - PGA syndrome type I: mucocutaneous candidiasis, hypoparathyroidism, and Addison disease

RISK FACTORS
Neck surgery and neck trauma, neck malignancies, family history of hypocalcemia, PGA syndrome

GENERAL PREVENTION
Intraoperative identification and preservation of parathyroid tissue

COMMONLY ASSOCIATED CONDITIONS
DiGeorge syndrome  
Barter syndrome  
PGA syndrome type I  
Multiple endocrine deficiency autoimmune candidiasis (MEDAC) syndrome  
Juvenile familial endocrinopathy  
Addison disease  
Moniliasis (HAM) syndrome: a polyglandular deficiency syndrome, possibly genetic, characterized by hypoparathyroidism

DIAGNOSIS

HISTORY
Often asymptomatic; ask about previous neck trauma or surgery, head or neck irradiation, family history of hypocalcemia, or presence of other autoimmune endocrinopathies.

Cardinal clinical feature: neuromuscular hyperexcitability

Also includes: fatigue, circumoral or distal extremity paresthesias, muscle spasm, seizures, neuropsychiatric symptoms

PHYSICAL EXAM

Surgical scar on neck

Chvostek sign: ipsilateral twitching of the upper lip on tapping the facial nerve on the cheek. 15% of normocalcemic people have positive sign (1).

Trousseau sign: painful carpal spasm after 3-minute occlusion of brachial artery with BP cuff. BP cuff inflation to above systolic BP for 3 minutes leads to carpal spasm (flexion of metacarpophalangeal [MCP] joints, extension of interphalangeal [IP] joints, adduction of fingers and thumb).

Tetany, laryngo- or bronchospasm, cardiac arrhythmias, refractory heart failure, dyspnea, edema

Dry, coarse, puffy hair; brittle nails

Loss of deep tendon reflexes

Dysrhythmias (secondary hypocalcemia)

Cataracts or ectopic calcifications

Tooth enamel defects

Vitiligo

DIFFERENTIAL DIAGNOSIS

Vitamin D deficiency/resistance

Pseudohypoparathyroidism, which presents in childhood; kidney and bone unresponsiveness to PTH; characterized by hypocalemia, hyperphosphatemia, and, in contrast to hypoparathyroidism, elevated rather than reduced PTH concentrations

Hypoalbuminemia, renal failure, malabsorption, familial hypocalcemia, hypomagnesemia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Calcium: ionized (low) and total (low) (correct serum calcium level for albumin)

Corrected serum calcium = total serum calcium + 0.8 (4 − serum albumin)
Phosphorus (high)
- Intact or “whole” PTH (low); how to distinguish from pseudohypoparathyroidism or secondary causes
- Magnesium (low may be cause of hypoparathyroidism; may also be normal)
- Blood urea nitrogen, creatinine, 25-OH vitamin D level (especially in elderly)
- Urinary calcium (normal or high)
- Calcium should be monitored after thyroid or parathyroid surgery.
- Radiographs may show absent tooth roots, calcification of cerebellum, choroid plexus, or cerebral basal ganglia.

Follow-Up Tests & Special Considerations
- ECG: prolongation of ST and QTc intervals, nonspecific repolarization changes, dysrhythmias
- Urine calcium: Creatinine ratio (normal 0.1 to 0.2) may be low before treatment but should be monitored to prevent stones due to hypercalciuria.
- Gene sequencing: Evaluation of other hormone levels may be required to diagnose APS-1.
- Hungry bone syndrome (transient hypoparathyroidism after parathyroid surgery)
  - Hypocalcemia due to hungry bone syndrome may persist despite recovery of PTH secretion from the remaining normal glands. Thus, serum PTH concentrations may be low, normal, or even elevated.
- Infiltrative: osteoblastic metastasis of prostate, breast, or lung cancer
- Metabolic/nutritional: renal failure, neonatal hypocalcemia, hypoalbuminemia, malabsorption, calcium (Ca\(^{++}\)) chelators, and hypomagnesemia
- Familial hypocalcemia, acute hyperphosphatemia (rare), vitamin D deficiency
- Autoantibodies against NACHT leucine-rich-repeat protein 5 (NALPS) found in 49% of 73 patients with APS-1 and hypoparathyroidism

**TREATMENT**

**GENERAL MEASURES**
- Monitor ECG during calcium repletion.
- Maintenance therapy: may require lifelong treatment with calcium and calcitriol
  - Maintain serum calcium in low normal range: 8 to 8.5 mg/dL (2.00 to 2.12 mmol/L).
- If hypercalcemia occurs, hold therapy until calcium returns to normal. Treat magnesium deficiency if present.
- Phosphate binders are required if high calcium-phosphate product.
- Thiazide diuretics combined with a low-salt diet may be used to prevent hypercalciuria, nephrocalcinosis, and nephrolithiasis.
- Oral calcium administration and vitamin D supplementation after thyroidectomy may reduce the risk for symptomatic hypocalcemia after surgery.

**MEDICATION**
- Acute hypoparathyroidism
  - Hypoparathyroid with severe symptoms (tetany, seizures, cardiac failure, laryngospasm, bronchospasm)
    - IV calcium gluconate: 1 or 2 g, each infused over a period of 10 minutes. Central venous catheter is preferred because calcium-containing solutions can irritate surrounding tissues.
Follow with infusion of 10 g calcium gluconate in 1 L 5% dextrose water at a rate of 1 to 3 mg calcium gluconate per kg body weight per hour (2)[B].

- Hypomagnesemia: acutely: 1 to 2 g IV q6h; long-term magnesium oxide tablets (600 mg) once or twice per day

- Chronic hypoparathyroidism

**First Line**

- **Adults**
  - Oral calcium carbonate: calcium salts: Start with 1 to 3 g/day PO but dose varies. For geriatric patients, those on a proton pump inhibitor or those who have constipation on the carbonate form, consider using calcium citrate instead (4)[B].
  - Calcitriol (vitamin D 1, 25-dihydroxycholecalciferol): 0.25 μg/day. Doses 0.5 to 2.0 μg/day are usually required (3)[A].
  - Either parental form of vitamin D (D<sub>2</sub> ergocalciferol or D<sub>3</sub> cholecalciferol) for tissues to generate their own 1,25 form
  - For hypercalciuria, consider a thiazide diuretic.
  - For phosphate level well above normal (>6.5 mg/dL), use low phosphate diet or phosphate binder.

- **Children**
  - Oral elemental calcium: 25 to 50 mg/kg daily
  - Calcitriol: 0.25 μg daily for age >1 year

**ISSUES FOR REFERRAL**
Endocrinologist, nephrologist, ophthalmologist

**ADDITIONAL THERAPIES**
PTH peptides 1–34 and 1–84 SC
- rhPTH 1–84— Food and Drug Administration (FDA) approved, 50 μg SC daily
- For patients with frequent episodes of hyper- and hypocalcemia, nephrolithiasis, nephrocalcinosis, glomerular filtration rate (GFR) <60 mL/min, persistently high phosphate (4)[B]
- Treatment goal: Eliminate use of active vitamin D<sub>3</sub>, reduce supplemental calcium to 500 mg daily; maintain consistent Ca level in low normal range.
- Improved well-being and increased bone mineral density have been shown for these patients.

**SURGERY/OTHER PROCEDURES**
Autotransplantation of cryopreserved parathyroid tissue: restores normocalcemia in 23% of cases

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission criteria/initial stabilization: laryngospasm, seizures, tetany, QT prolongation
- Discharge criteria: resolution of hypocalcemic symptoms, patient educated on hypoparathyroidism and treatment

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Patient Monitoring

- Goal is a total corrected serum calcium level in low normal range (8.0 to 8.5 mg/dL or 2.0 to 2.12 mmol/L), 24-hour urine calcium <300 mg, and calcium-phosphate product <55. If Ca <2.0 mmol/L or <8.0 mg/dL, then treat even if asymptomatic [4][B].
- Outpatient measurement of serum calcium, phosphate, magnesium, and creatinine weekly to monthly during initial management; for changes in medication, check weekly or every other week; when stable, measure every 6 months [4][B].
- 24-hour urine for calcium and Cr secretion yearly
- If symptoms of renal stone disease or increasing Cr, get renal imaging every 5 years [4][B].
- Annual slit-lamp and ophthalmologic evaluations are recommended.
- Dual energy x-ray absorptiometry scan: standard monitoring recommended [4][B]

DIET
Low-phosphate diet in patients with hyperphosphatemia

PATIENT EDUCATION
https://www.hypopara.org/

PROGNOSIS
Hypoparathyroidism following neck surgery is often transient. Length of required treatment may vary depending on origin.

COMPLICATIONS
- Reversible: due to low calcium levels, most likely to improve with adequate treatment
  - Neuromuscular symptoms: Paresthesias (circumoral, fingers, toes), tetany, seizures, parkinsonian symptoms; pseudotumor cerebri has been described.
  - Renal: hypercalciuria, nephrocalcinosis, nephrolithiasis
  - Cardiovascular: heart failure, arrhythmias
- Irreversible: when condition starts early in childhood and will not improve with calcium and vitamin D treatment
  - Stunting of growth
  - Enamel defects and hypoplasia of teeth
  - Atrophy, brittleness, and ridging of nails
  - Cataracts and basal ganglia calcifications

REFERENCES
ADDITIONAL READING

CODES

ICD10
- E20.9 Hypoparathyroidism, unspecified
- P71.4 Transitory neonatal hypoparathyroidism
- E89.2 Postprocedural hypoparathyroidism

CLINICAL PEARLS

Often asymptomatic; consider if hypocalcemic with fatigue and circumoral or distal extremity paresthesias.
- Correct the serum calcium level for albumin level.
- Monitor calcium after thyroid or parathyroid surgery.
- Distinguish hypoparathyroidism from pseudohypoparathyroidism and secondary causes by PTH level.
- Not much clinical difference between 2nd- and 3rd-generation PTH assays
- Serum levels of magnesium and 25-OH should be measured to rule out deficiency that could contribute to reduced serum calcium levels.
BASICS

DESCRIPTION
- Accidental hypothermia is the result of an unanticipated environmental exposure to cold temperatures. It is manifested as a core temperature of <35°C (95°F).
- May take several hours to days to develop.
- Patients with cold-water immersion may appear dead but can sometimes still be resuscitated.
- System(s) affected: all body systems
- Synonym(s): accidental hypothermia

EPIDEMIOLOGY
- Predominant age: very young and the elderly
- Predominant sex: male > female

Geriatric Considerations
More common in elderly due to lower metabolic rate, impaired ability to maintain normal body temperature, and impaired ability to detect temperature changes

Incidence
From 1999–2011, the Centers for Disease Control and Prevention reported 16,911 deaths due to hypothermia.

Prevalence
Estimates vary widely; typically a secondary issue

ETIOLOGY AND PATHOPHYSIOLOGY
Core temperature is typically tightly maintained between 36.5°C and 37.5°C. Accidental hypothermia is most often the result of overwhelming environmental cold stress. Other contributing factors include:
- Decreased heat production (e.g., hypopituitarism; hypothyroidism; adrenal insufficiency)
- Increased heat loss (e.g., immersion—this is the most commonly encountered form of hypothermia in emergency situations—or burns)
- Impaired thermoregulation (e.g., stroke, central nervous system [CNS] tumors)

RISK FACTORS
- Alcohol consumption
- Bronchopneumonia
- Cardiovascular disease
- Cold-water immersion
- Dermal dysfunction (burns, erythrodermas)
- Drug intoxication
- Endocrinopathies (myxedema, severe hypoglycemia)
- Excessive fluid loss
- Hepatic failure
Hypothalamic and CNS dysfunction
- Malnutrition
- Mental illness; Alzheimer disease
- Prolonged cardiac arrest
- Prolonged environmental exposure
- Renal failure
- Sepsis
- Trauma (especially head)
- Uremia

**GENERAL PREVENTION**
- Appropriate clothing, with particular attention to head, feet, and hands
- For outdoor activities, carry survival bags with rescue foil blanket for use if stranded or injured
- Avoid alcohol
- Alertness to early symptoms and initiating preventive steps (e.g., drinking warm fluids)
- Identify medications that may predispose to hypothermia (e.g., neuroleptics, sedatives, hypnotics, tranquilizers)

**COMMONLY ASSOCIATED CONDITIONS**
- Addison disease
- CNS dysfunction
- Congestive heart failure
- Diabetes
- Hypopituitarism
- Hypothyroidism
- Ketoacidosis
- Pulmonary infection
- Sepsis
- Uremia

**DIAGNOSIS**

**HISTORY**
- Presentation varies with the temperature of the patient at the time of presentation.
- The history is often apparent in the setting of outdoor environmental exposures. It may be less clear with cold indoor environments. Patients can present with confusion, dizziness, dyspnea, alterations in judgment. Taking a careful history is particularly important in cases of “indoor hypothermia.”

**ALERT**
History of prolonged exposure to cold may make the diagnosis obvious, but hypothermia may be overlooked in other situations, especially in comatose patients. Always obtain a core temperature if hypothermia is suspected.

**PHYSICAL EXAM**
- Esophageal temperature is most accurate, minimally invasive method of assessing core temperature (1)[C]
Must have secure airway
Probe inserted into lower 3rd of esophagus
Peripheral thermometers (tympanic membrane, temporal artery, axillary, or oral) associated with reduced accuracy

Exam findings vary with the temperature of the patient at the time of presentation.

- Mild (32–35°C)
  - Lethargy and mild confusion
  - Shivering
  - Tachypnea
  - Tachycardia
  - Loss of fine motor coordination
  - Increased BP
  - Peripheral vasoconstriction
  - Hyperactive reflexes
- Moderate (28–32°C)
  - Delirium
  - Bradycardia
  - Hypotension
  - Hypoventilation
  - Cyanosis
  - Arrhythmias (prolonged PR interval, AV junctional rhythm, accelerated idioventricular rhythm, prolonged QT interval, altered T waves)
  - Semicoma and coma
  - Muscular rigidity
  - Generalized edema
  - Slowed reflexes
- Severe (<28°C)
  - Very cold skin
  - Rigidity
  - Apnea
  - Bradycardia
  - No pulse: ventricular fibrillation or asystole
  - Areflexia
  - Unresponsive
  - Pupils (dilated <27°C; fixed and dilated <27°C)

**ALERT**
Use specially designed thermometers that can record low temperatures and measure core temperatures.

**Pediatric Considerations**
- Infants may present with bright red, cold skin and very low energy.
- A child’s body temperature drops faster than an adult’s does when immersed in cold water.
- Altered mental status is the most important clue to significant hypothermia in children.

**DIFFERENTIAL DIAGNOSIS**
- Cerebrovascular accidents
Intoxication
Drug overdose
Complications of diabetes, hypothyroidism, hypopituitarism

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Arterial blood gases (corrected for temperature)
- CBC and platelet counts
- Serum electrolytes; blood urea nitrogen/creatinine; glucose; calcium; magnesium
- Urinalysis
- Coagulation studies; fibrinogen level
- Blood culture
- Liver function studies; amylase
- Cardiac enzymes
- Alcohol level and toxicology screen
- Cervical spine, chest, and abdomen x-rays, if appropriate
- Bedside ultrasound to assess hemodynamics
- CT of the head for any concern regarding mental status

**Follow-Up Tests & Special Considerations**
Serum cortisol and thyroid-stimulating hormone if underlying endocrine dysfunction (hypothalamus stimulates release of hormones in response to hypothermia)

**Diagnostic Procedures/Other**
ECG

**Test Interpretation**
Serum potassium >12 mmol/L associated with nonsurvival

**TREATMENT**

**GENERAL MEASURES**
- Prehospital (1)[C]
  - Factors to guide treatment
    o Level of consciousness
    o Shivering intensity
    o Cardiovascular stability based on blood pressure and cardiac rhythm
  - Treatment
    o ABCs of basic life support
    o Remove wet garments.
      ■ Dry patient.
    o Protect against heat loss and wind chill.
      o If mildly hypothermic, with significant endogenous heat production from shivering, will likely be able to rewarm themselves with insulation and a vapor barrier; active rewarming will provide comfort and an energy-saving benefit (2)[A].
      o For colder, nonshivering patients, the addition of active warming is indicated as a nonshivering patient will not rewarm spontaneously (2)[A].
All intravenous fluids must be reliably warmed before infusion. Give warm humidified oxygen if available. If far from definitive care, begin active rewarming but do not delay transport.

See “Admission, Inpatient, and Nursing Considerations”

**MEDICATION**

- For sepsis or bacterial infections: antibiotics based on site and etiology of underlying infection
- For hypoglycemia: D50W at a dose of 1 mg/kg
- Thiamine: 100 mg, if alcoholic or cachectic
- Naloxone: 2 mg if opioid use suspected
- Levothyroxine: 150 to 500 μg for myxedema
- For severe acidosis: consider sodium bicarbonate

**Precautions**

- Medications including epinephrine, lidocaine, and procainamide can accumulate to toxic levels if used repeatedly; avoid until core temperature is >30°C:
  - When temperature reaches >30°C, IV medications are indicated. Administer slowly.
- Consider vasopressors according to standard advanced cardiovascular life support algorithm with concurrent rewarming in setting of cardiac arrest.

**Significant possible interactions:**

- Use all drugs cautiously due to impaired metabolism and renal elimination.
- Once rewarming has occurred, there is mobilization of depot stores.
- Routine use of steroids or antibiotics does not increase survival or decrease postresuscitative damage.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Rewarming depends on severity of hypothermia and presence of cardiac arrest.
  - If no cardiac arrest, consider active external rewarming.
  - If cardiac arrest is present, consider active internal rewarming (3)[B].

**Warm center of body first (4)[C]**

- Don’t rewarm frostbitten extremities until core temperature is >34°C.

**The rate of rewarming is determined by whether a perfusing cardiac output is present.**

- If a perfusing cardiac output is present, 1–2°C/hr is appropriate.
- If not, then a faster rate of >2°C/hr should be used.

- Monitor core temperature; use a consistent method.
- Monitor BP and cardiac rhythm.
- Correct metabolic acidosis.
- Evaluate for frostbite and other trauma.

**Mild hypothermia**

- Passive rewarming
- Administration of heated IV solutions
- Provide warm fluids by mouth if fully alert.

**Moderate hypothermia**

- Active external rewarming
- Administration of heated IV solutions

**Severe hypothermia (active internal [core] rewarming)**

- Heated IV fluids
- Heated humidified oxygen
- Extracorporeal life support (preferred method in cardiac arrest (5)[C])
  - Cardiopulmonary bypass
  - Extracorporeal membrane oxygenation
- Body cavity lavage (second options)
  - Thoracic cavity lavage (40–45°C)
  - Peritoneal lavage (40–45°C)
  - Continuous arteriovenous rewarming
  - Hemodialysis and hemofiltration

- Cardiac arrhythmias
  - Atrial fibrillation and sinus bradycardia are common—patients usually convert to normal sinus rhythm with rewarming.
  - If ventricular fibrillation is present, treat with one shock. If patient does not respond, consider deferring further attempts until rewarm has occurred.
  - Do not treat transient ventricular arrhythmias.
  - If cardiac pacing required, preferable to use external noninvasive pacemaker
- Admit patients, preferably to the ICU, with underlying disease, physiologic abnormalities, or core temperature <32°C.
- Normal saline is preferred as fluid of choice (1)[C].
- Heat IVs from 40°C to 45°C if possible—should at least be no colder than patient core temperature.

**ALERT**
- Avoid fluid overload.
- Avoid overheating dextrose solutions; dextrose caramelizes at 60°C.
- Avoid lactated Ringer solution because of decreased lactate metabolism.
- Heart is irritable and susceptible to arrhythmias; take care transporting.
- Electrolytes may fluctuate with rewarming, check electrolytes (particularly potassium) frequently.
- Discharge from emergency department once normothermic, if mild hypothermia and no predisposing conditions or complications and has suitable place to go. All others require admission.

---

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- During acute episode
  - Monitor cardiac rhythm.
  - Monitor electrolytes and glucose frequently.
  - Monitor urinary output.
  - Follow blood gases.
- Following acute episode
  - Continued therapy for any underlying disorder

**DIET**
Warm fluids only if alert and able to swallow
• Alcohol intake increases risk of becoming hypothermic in cold conditions.
• Encourage persons with cardiovascular disease to avoid outdoor exercise in cold weather.
• Refer to social service agency for help with adequate housing, heat, and/or clothing, if appropriate.

PROGNOSIS
• Mortality rates are decreasing due to increased recognition and advanced therapy.
• Mortality usually depends on age and the severity of underlying cause and comorbidities.
  – Mortality rate in healthy patients is <5%.
  – Mortality rate with coexisting illness is >50%.
  – Alcohol or drug poisoning seen in 10% of deaths

Geriatric Considerations
Mortality rates increase with increasing age. Over half of deaths are seen in patients >65 years.

COMPLICATIONS
• Core temperature after drop
• Cardiac arrhythmias
• Hypotension
• Hyperkalemia, hypoglycemia
• Rhabdomyolysis
• Sepsis
• Pneumonia (aspiration and bronchopneumonia), pulmonary edema
• Acute respiratory distress syndrome
• Pancreatitis, peritonitis, GI bleeding, ileus
• Acute tubular necrosis, bladder atony
• Intravascular thromboses/disseminated intravascular coagulation
• Metabolic acidosis
• Gangrene of extremities
• Compartment syndromes
• Seizures, cerebral ischemia, delirium

SEE ALSO

- Frostbite; Nonfatal Drowning
- Algorithm: Hypothermia

CODES

ICD10

- T68.XXXA Hypothermia, initial encounter
- T68.XXXD Hypothermia, subsequent encounter
- T68.XXXXS Hypothermia, sequela

CLINICAL PEARLS

- The most common cause of hypothermia in the United States is cold exposure due to alcohol intoxication.
- With a severely decreased core temperature, begin resuscitation (if possible) unless there are obvious lethal injuries. Continue resuscitation and rewarm to 33–35°C (“not dead until warm and dead”).
- ECG changes associated with hypothermia: slowing of sinus rate with T-wave inversion; QT, QRS, and PR interval prolongation; atrial and ventricular arrhythmias; J waves (Osborn waves)
- Hypothermia, coagulopathy, and acidosis are the trauma triad associated with higher rates of death.
HYPOTHYROIDISM, ADULT
Faraz Ahmad, MD, MPH ● Hiba Ahmad, PharmD ● Christen D. Johnson, MD, MPH

BASICS

DESCRIPTION
- Clinical and metabolic state resulting from decreased levels of free thyroid hormone or from resistance to hormone action
- Primary (intrinsic thyroid disease) or central (secondary or tertiary resulting from hypothalamic-pituitary disease)
- Subclinical: serum thyroid-stimulating hormone (TSH) above the upper reference limit with a normal free thyroxine (T4) and normal hypothalamic-pituitary-thyroid axis (1)
- Overt: elevated TSH, usually >10 mIU/L with a subnormal free T4

EPIDEMIOLOGY

Incidence
- Women: 3.5/1,000 persons per year
- Men: 0.6/1,000 persons per year

Prevalence
- The National Health and Nutrition Examination Survey III (NHANES III), subclinical hypothyroidism 9.3%, overt 0.3–3.7% in an unselected U.S. population age >12 years, with upper limit TSH 4.5
- Framingham study, 5.9% of women and 2.3% of men age >60 years had a serum TSH >10 mIU/L.

ETIOLOGY AND PATHOPHYSIOLOGY

Primary: abnormality at the thyroid gland (>95% of cases)
- Most common cause worldwide: environmental iodine deficiency (1)[A]
- Most common cause in the United States: Hashimoto thyroiditis (chronic autoimmune thyroiditis)
  - Hashimoto is characterized by loss of thyroid function secondary to damage caused by the attrition of T lymphocytes by antithyroid antibodies.
  - Autoimmune antithyroid antibodies are the result of an inherited defect leading to the disruption in the immune system, which leads to the recognition of self-antigens as foreign (1).
- Postablative/posttherapeutic: follows radioactive iodine therapy or hemithyroidectomy for hyperthyroidism; radiotherapy or surgery for thyroid cancer, benign nodular thyroid disease, or neck malignancies
- Transient hypothyroidism: de Quervain syndrome (viral), postpartum, silent thyroiditis (2)
- Drug use: propylthiouracil, methimazole, lithium, amiodarone, antiepileptic drugs, and newer chemotherapeutic agents such as tyrosine kinase inhibitors (sunitinib), interleukin-2, or interferon-α
- Central: hypothyroidism due to insufficient stimulation by TSH of an otherwise normal thyroid
gland
- Can be secondary (level of the pituitary) or tertiary (level of the hypothalamus)
- Consumptive: T3 and T4 consumed by type 3 iodothyronine deiodinase produced by a tumor causing low circulating hormone levels
- Etiology involves genetic defects, tumors, vascular, empty sella syndrome, inflammatory, infiltrative, iatrogenic, posttrauma, or drug related.

**RISK FACTORS**
- Women >60 years of age
- Personal or family history of autoimmune diseases
- Pregnant women or those with previous postpartum thyroiditis
- Previous head or neck irradiation
- Past history of thyroid dysfunction or thyroid surgery
- Abnormal thyroid examination, presence of goiter and/or TPOAb positivity
- Treatment with amiodarone, lithium, interferon-α, sunitinib, or sorafenib
- Down syndrome or Turner syndrome
- Diagnosis of other autoimmune diseases

**COMMONLY ASSOCIATED CONDITIONS**
- Diabetes mellitus type 1 and 2
- Pernicious anemia
- Primary adrenal failure (Addison disease)
- Myasthenia gravis
- Celiac disease
- Rheumatoid arthritis
- Systemic lupus erythematosus
- Vitiligo
- Depression
- Genetic syndromes that have multiple autoimmune endocrinopathies (MAE) such as type 1 MAE and type 2 MAE

**DIAGNOSIS**

**HISTORY**
Symptoms can vary and can be nonspecific.
- Lethargy
- Fatigue
- Cold intolerance
- Slowed thinking
- Hearing impairment
- Constipation
- Dry skin
- Muscle cramps, arthralgias, paresthesias
- Modest weight gain (10 lb [4.5 kg])
- Menstrual disturbances
- Depression
- Change in voice (hoarseness)
- Sleep apnea
- Carpal tunnel syndrome

**PHYSICAL EXAM**
- Dry, coarse, thickened skin
- Hair loss/brittle hair
- Coarsening of voice
- Periorbital puffiness
- Swelling of hands and feet (nonpitting)
- Bradycardia
- Reduced systolic BP; increased diastolic BP
- Delayed relaxation of deep tendon reflexes
- Macroglossia
- Goiter (particularly in patients with Hashimoto thyroiditis)

**Geriatric Considerations**
- Characteristic signs and symptoms frequently nonspecific, changed, or absent
- Normal serum thyrotropin ranges are higher (in those >65 years of age).

**DIFFERENTIAL DIAGNOSIS**
- Chronic fatigue syndrome
- Depression
- Euthyroid sick syndrome
- Congestive heart failure
- Primary amyloidosis
- Dementia from other causes
- Primary adrenal insufficiency
- Thyrotropin-secreting pituitary adenoma

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Primary hypothyroidism
  - Elevated TSH (>4.5 mIU/L)
  - Decreased serum free T\textsubscript{4} (2)[A]
- Central (secondary or tertiary) hypothyroidism
  - Assess free T\textsubscript{4} or free T\textsubscript{4} index (1)[A].
  - Decreased serum free T\textsubscript{4}
  - Antithyroid antibodies absent
  - Thyrotropin-releasing hormone stimulation test, especially if free T\textsubscript{4} and/or TSH is low-normal and patient has hypothalamo-pituitary pathology
  - Imaging of the hypothalamus and pituitary gland
- Subclinical hypothyroidism
  - Elevated serum TSH (>4.5 mIU/L)
  - Normal serum free T\textsubscript{4} (3)[A]
  - Note: Serum free triiodothyronine (T\textsubscript{3}) or total T\textsubscript{3} should not be done to diagnose
hypothyroidism (1)[A].

Follow-Up Tests & Special Considerations

- Antithyroid antibodies may define the cause of primary hypothyroidism but are not necessary in all settings.
- Drugs that may alter lab results:
  - Drugs that decrease TSH:
    - Thyroid supplement, cortisone, dopamine, octreotide
  - Drugs that increase TSH:
    - Phenytoin, amiodarone, dopamine antagonist (metoclopramide/domperidone, salicylates, oral cholecystographic dyes [sodium ipodate]), or estrogen or androgen in excess
  - Drugs that increase free $T_4$:
    - Heparin, high intake of biotin
- Disorders that may alter lab results
  - Any severe illness, pregnancy, chronic protein malnutrition, hepatic failure, or nephrotic syndrome

Test Interpretation

Screening

- Patient with risks factors as described above (1)[A]
- Patient with laboratory or imaging abnormalities
  - Substantial hyperlipidemia or change in lipid pattern
  - Hyponatremia, often resulting from inappropriate production of antidiuretic hormone
  - High serum muscle enzyme concentrations
  - Macrocytic anemia
  - Pericardial or pleural effusion
  - Pituitary or hypothalamic disorder
- Pregnant women
  - Personal or family history of thyroid disease
  - Diabetes mellitus type 1
  - H/o recurrent miscarriage, morbid obesity, or infertility; TPOAb should be considered (1)[A].
  - Universal screening not recommended for patients pregnant or planning pregnancy

U.S. Preventive Services Task Force found insufficient evidence for or against screening nonpregnant, asymptomatic children or adults (2)[A].

Recommendations by expert groups:

- Anti-topoisomerase recommends screening in all adults at age 35 years and every 5 years thereafter (1)[C].
- AACE recommends screening older patients (age not specified), especially women.
- American Academy of Family Physicians recommends against routine screening in asymptomatic patients <60 years.
- American College of Obstetricians and Gynecologists recommends women with h/o autoimmune disease or strong family h/o thyroid disease should be screened at age 19 years.
MEDICATION

First Line

- Levothyroxine (Synthroid, Levothroid)
  - 1.5 to 1.8 μg/kg/day (use ideal body weight) [2][A]; titrate by 12.5 to 25.0 μg/day every 4 to 8 weeks until TSH in normal range.
  - Dosage requirements may vary with age, gender, residual secretory capacity of thyroid gland, other drugs being taken by patient, and intestinal function [1][A].
  - Use caution when changing between capsule, tablet, and injection because dose conversions are not a 1:1 ratio.
  - Elderly patients may require 2/3 of dose used in young adults because clearance is decreased.
  - Levothyroxine should be taken on an empty stomach, ideally an hour before breakfast. Administering at bedtime may result in higher levels than administering in the morning [4][A].
  - Medications that interfere with its absorption should be taken 4 hours after the T4 dose: ferrous sulfate, proton pump inhibitors, calcium carbonate, bile acid resins.

- Contraindications
  - Thyrotoxic heart disease
  - Uncorrected adrenocorticoid insufficiency
  - Myocardial infarction, acute
  - TSH suppression, preexisting

- Precautions
  - If elderly or known coronary artery disease, start with lower doses, such as 12.5 to 25.0 μg.
  - Diabetic patients may need readjustment of hypoglycemic agents with institution of T4.
  - Dosage of oral anticoagulants may need adjustment; monitor prothrombin time while initiating treatment.
  - Patients on digoxin may need close monitoring.
  - Elderly patients more susceptible to AFib and osteoporotic fracture with thyroid hormone excess
  - Patients requiring doses that are higher than expected should be evaluated for gastrointestinal disorders (Helicobacter pylori, celiac disease).

- Possible interactions with the following medications:
  - Oral anticoagulants, insulin, oral hypoglycemic, estrogen, oral contraceptive pill, proton pump inhibitor, cholestyramine
  - Ferrous sulfate, calcium carbonate, antacids, laxatives, colestipol, sucralfate, ciprofloxacin, and cholestyramine may decrease absorption.

- Controversy exists whether subclinical hypothyroidism should be treated. Cochrane Review found no improvement in survival, cardiovascular morbidity, or health-related quality of life. Some evidence indicates improvement in lipid profiles and left ventricular function. Subclinical hypothyroidism should be treated in patients with iron deficiency anemia and in patients with TSH >10 [3,5][B].

- If surgery is elective, render patient euthyroid prior to procedure.
- If surgery is urgent, proceed with individualized replacement therapy preoperatively and postoperatively.
- Brand and generic T4 formulations available. Questionable equivalent efficacy of preparation
when switching between manufactures; can measure serum TSH 6 weeks after changing manufactures

**Pregnancy Considerations**
- Replacement therapy may need adjustment; average dose increases from 25% to 50% (6)[A].
- TSH levels should be monitored monthly during 1st trimester; goal TSH of 2.0 to 2.5 mIU/L for 1st trimester, <3.0 mIU/L for 2nd trimester, and <3.5 mIU/L for 3rd trimester (6)[A]
- Postpartum: Check TSH levels at 6 weeks (6)[A].
- Painless subacute thyroiditis may occur in postpartum period, leading to transient hypothyroidism lasting 3 months. Treatment with replacement therapy may be warranted. Up to 30% of these individuals develop permanent hypothyroidism.

**Second Line**
- No benefit to adding T₃ to T₄ (6)[A]
- Desiccated thyroid hormone is not recommended for the treatment of hypothyroidism (1).
- Liothyronine (T₃) or desiccated thyroid hormone (T₃ and T₄) may be an alternative for patients who do not feel balanced on T₄ alone.

**ISSUES FOR REFERRAL**
- Children and infants
- Pregnancy or women planning conception
- Patient in whom it is difficult to maintain a euthyroid state
- Cardiac disease
- Presence of goiter, nodule, or other structural changes in the thyroid gland
- Presence of adrenal or pituitary disorders (1)[C]

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Myxedema coma (decompensated severe untreated hypothyroidism)
- True clinical emergency (requires ICU care)
- Profound hypothermia and unconscionness
- Increased risk of shock and potentially fatal arrhythmias
- Postponing surgery for initiating therapy for hypothyroidism is not indicated.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Monitor TSH and free T₄ every 4 to 8 weeks after initiating treatment or after change in dose. Once stabilized, periodic TSH level should be done after 6 months and then at 12-month intervals or more frequently if the clinical situation dictates otherwise (1)[B].
- Monitor cardiac function closely in older patients.
- Check TSH more frequently during pregnancy, initiation of estrogen supplementation, or after large changes in body weight.
- In central hypothyroidism, TSH is unreliable; must monitor free T₄ and T₃.
- Thyroid hormones should not be used to treat obesity in euthyroid patients (1)[A].
PATIENT EDUCATION
- Stress importance of compliance with thyroid replacement therapy.
- Explain need for lifelong treatment.
- Further education required for patients taking multiple medications that may interact
- Instruct to report to physician any signs of infection or heart problems.
- Describe signs of thyrotoxicity.
- High-bulk diet may help avoid constipation.

PROGNOSIS
- Return to normal state is the rule.
- Relapses will occur if treatment is interrupted.
- If untreated, may progress to myxedema coma

COMPlications
- Mortality and complication rates from surgery are similar between hypothyroid and euthyroid patients.
- Myxedema coma: mortality 30–60%
- Increased susceptibility to infection
- Megacolon
- Sexual dysfunction
- Organic psychosis with paranoia
- Infertility
- Hypersensitivity to opiates
- Treatment over long periods can lead to bone demineralization.
- Iatrogenic thyrotoxicosis can lead to AFib and osteoporosis.
- Can lead to adrenal crisis with vigorous treatment, especially in patients with undiagnosed polyendocrine syndromes
- Treatment-induced congestive heart failure in people with coronary artery disease

REFERENCES
CODES

ICD10
- E03.9 Hypothyroidism, unspecified
- E06.3 Autoimmune thyroiditis
- E89.0 Postprocedural hypothyroidism

CLINICAL PEARLS
- Screening test: TSH levels; Serum free T₃ or total T₃ should not be done to diagnose hypothyroidism (1)[A].
- Monitor TSH and free T₄ every 4 to 8 weeks after initiating treatment or after change in dose. Once stabilized, periodic TSH level should be done after 6 months and then at 12-month intervals or more frequently if the clinical situation dictates otherwise.
**ID REACTION**  
Sahil Mullick, MD

---

**BASICS**

**DESCRIPTION**
A generalized skin reaction associated with various infectious (fungal, bacterial, viral, or parasitic) or inflammatory cutaneous conditions distant from the primary disease site (1).  
- “Id” is often combined with a root to reflect the causative factor (i.e., bacterid, syphilid, and tuberculid). Dermatophytid is the most frequently referenced id reaction. A dermatophytid is an autosensitization reaction in which a secondary cutaneous reaction occurs at a site distant to a primary fungal infection. The eruption typically begins within 1 to 2 weeks of the onset of the main lesion or following exacerbation of the main lesion.  
- Most commonly localized vesicular lesions, erythema nodosum, and erythema multiforme  
- System(s) affected: skin/exocrine  
- Synonym(s): dermatophytid, trichophytid, autoeczematization

**EPIDEMIOLOGY**
- Predominant age: all ages  
- Predominant sex: male = female  
- Predominant race: all races

**Incidence**  
Unknown

**Prevalence**  
Common

**ETIOLOGY AND PATHOPHYSIOLOGY**
Precise pathophysiology is uncertain. Circulating antigens may react with antibodies at sensitized areas of the skin. An abnormal immune recognition of autologous skin antigens may also occur. Inflammation may lower the irritation threshold of the skin, and hematogenous spread of cytokines from the primary site of inflammation may also play a role (1).  
- Etiology  
  - Infectious  
    - Fungal infections: Trichophyton mentagrophytes, Trichophyton rubrum, Epidermophyton floccosum, and Candida spp.  
    - Bacterial infections: Streptococcus pyogenes, Staphylococcus aureus, and Mycobacterium tuberculosis  
    - Viral infections: HSV, Molluscum contagiosum, orf, and milker’s nodules  
    - Parasitic infections: Sarcopes scabiei and Leishmania spp.  
  - Allergic  
    - Id reactions occur in patients with nickel and aluminum allergy.  
  - Miscellaneous  
    - Id reaction rarely develops due to retained postoperative sutures, ionizing radiation, and blunt trauma.
Rarely, id reaction has been documented in patients receiving intravesical BCG live therapy for transitional cell carcinoma.

**RISK FACTORS**
- Fungal infection of the skin, especially tinea pedis
- Stasis dermatitis

**GENERAL PREVENTION**
- Good skin hygiene (particularly in intertriginous areas) to minimize risk of developing fungal infections
- Promptly treat any developing fungal infection.

**COMMONLY ASSOCIATED CONDITIONS**
- Primary fungal infection
- Stasis dermatitis

**DIAGNOSIS**

**HISTORY**
Itchy rash: Inquire about presence of lesions (typically fungal or bacterial) that could have incited the id reaction in the preceding days to weeks.

**PHYSICAL EXAM**
- Common
  - Symmetric, pruritic vesicles on the palms and, most commonly, on lateral aspects of fingers
  - Tinea infection on the feet; contact or other eczematosus dermatitis; bacterial, fungal, or viral infection of the skin
- Less common
  - Papules
  - Lichenoid eruption
- Eczematoid eruption

**DIFFERENTIAL DIAGNOSIS**
- Pompholyx (dyshidrotic eczema)
- Contact dermatitis
- Drug eruptions
- Pustular psoriasis
- Folliculitis
- Scabies

**DIAGNOSTIC TESTS & INTERPRETATION**
- Potassium hydroxide (KOH) or fungal culture of primary lesion
- No fungal elements are present at the site of the id reaction.
- Special tests: Skin shows a positive trichophyton reaction. A wheal >10 mm at 20 minutes and induration >5 mm at 72 hours is a positive response.

**Follow-Up Tests & Special Considerations**
- The id reaction resolves with successful eradication of the primary skin condition.
It is important to distinguish dermatophytids from drug-induced allergic reactions because continued treatment is essential to clear the underlying infection.

Test Interpretation

Histology
- Vesicles in the upper dermis
- Superficial perivascular lymphohistiocytic infiltrate with small numbers of eosinophils and increased granular cell layer
- No infectious agents present in biopsy specimen.

TREATMENT

GENERAL MEASURES
- Outpatient treatment of the underlying infection or eczematous dermatitis
- Symptomatic treatment of pruritus with antihistamines and/or topical steroids if needed (may require class 1 or 2 steroid)
- Treatment for secondary bacterial infection

MEDICATION

First Line
- PO antihistamines for pruritus (2)
  - Chlorpheniramine: 4 mg PO q4–6h PRN; max 24 mg/24 hr (pediatric: 6 to 11 years 2 mg PO q4–6h PRN; max 12 mg/24 hr; ≥12 years, refer to adult dosing)
  - Diphenhydramine: 25 to 50 mg PO q4–6h PRN; max 400 mg/24 hr (pediatric: 5 mg/kg/24 hr divided q6h PRN; 2 to 5 years max 37.5 mg/24 hr; 6 to 11 years max 150 mg/24 hr; ≥12 years, refer to adult dosing)
  - Hydroxyzine: 25 to 100 mg PO q6–8h PRN; max 600 mg/24 hr (pediatric: 2 mg/kg/24 hr divided q6h PRN)
- Topical treatments for pruritus
  - Triamcinolone 0.1% ointment TID
  - Hydrocortisone 0.5%, 1%, 2.5%: up to QID
  - Capsaicin 0.025%, 0.075% cream: Apply TID–QID; EMLA (2.5% lidocaine + 2.5% prilocaine) applied 30 to 60 minutes prior to capsaicin may minimize burning.
  - Doxepin 5% cream: Apply QID for up to 8 days (to max of 10% of the body).
- Permethrin 5% cream (for scabies)
  - Apply from neck down after bath.
  - Wash off thoroughly with water in 8 to 12 hours.
  - May repeat in 7 days
- Permethrin 1% cream rinse (for lice)
  - Shampoo, rinse, towel dry, saturate hair and scalp (or other affected area), leave on 10 minutes and then rinse.
  - May repeat in 7 days
- White petroleum emollients: Apply after short bath/shower in warm (not hot) water.

Second Line

Systemic steroids only if reaction is severe or generalized (e.g., prednisone 20 mg)
Topical and/or systemic antifungals for identified associated fungal infection (common)
  - Tinea cruris/corporis
    - Topical azole antifungal compounds econazole (Spectazole) and ketoconazole (Nizoral): usually applied BID for 2 to 4 weeks
    - Terbinafine (Lamisil): over-the-counter (OTC) compound; can be applied daily or BID for 1 to 2 weeks
    - Butenafine (Mentax): applied once daily for 2 weeks; also very effective
  - Tinea capitis
    - PO griseofulvin for Trichophyton and Microsporum sp.; microsized preparation available; dosage 20 to 25 mg/kg/day divided BID or as a single dose daily for 6 to 12 weeks
    - PO terbinafine can be used for Trichophyton sp. at 62.5 mg/day in patients weighing 10 to 20 kg, 125 mg/day if weight 20 to 40 kg, 250 mg/day if weight >40 kg, and use for 4 to 6 weeks.

Topical or systemic antibiotics for any secondary bacterial infection
Treatment with antiviral agents for erythema multiforme associated with HSV is required.

ONGOING CARE

PATIENT EDUCATION
Avoid hot, humid conditions that promote fungal growth. Aerate susceptible body areas (e.g., wear sandals or open footwear). If possible, wear loose-fitting clothing and undergarments, dry wet skin after bathing, and use powders and antiperspirants to discourage fungal growth. Treat primary dermatitis promptly.

PROGNOSIS
After appropriate treatment, complete resolution in days to weeks

COMPLICATIONS
- Secondary bacterial infection (cellulitis)
- After resolution of dermatophytid, postinflammatory hyperpigmentation is common and disappears without treatment in 1 month.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- L30.2 Cutaneous autosensitization
- B35.9 Dermatophytosis, unspecified

CLINICAL PEARLS
- When one skin eruption follows another closely in time, consider an id reaction.
- When assessing an itchy rash, inquire about potential fungal or bacterial lesions in the preceding days to weeks as a potential prelude to the id reaction.
BASICS

DESCRIPTION

- Immune thrombocytopenia (ITP) is a condition characterized by the immunologic destruction of normal platelets and/or impaired thrombopoiesis in response to an unknown stimulus.
- It is defined as a platelet count <100 × 10^9/L, once other causes of thrombocytopenia have been ruled out (1).
- ITP nomenclature:
  - Newly diagnosed (<3 months), persistent (3 to 12 months), and chronic (>12 months)
  - Primary when it presents in isolation; secondary when associated with other disorders
- ITP is a relatively common disease of childhood that typically follows a viral infection. Onset is within 1 week, and spontaneous resolution occurs within 2 months in >80% of patients.
- In adults, ITP is usually a chronic disease and spontaneous remission is rare.
- Synonym(s): idiopathic thrombocytopenic purpura; immune thrombocytopenic purpura; and Werlhof disease

EPIDEMIOLOGY

- Peak age
  - Pediatric ITP: 2 to 4 years
  - Chronic ITP: >50 years with incidence 2 times higher in persons 60 years than those <60 years of age
- Predominant gender
  - Pediatric ITP: male = female
  - Chronic ITP: female > male (1.2 to 1.7:1)

Incidence

- Pediatric acute ITP: 1.9 to 6.4/100,000 children per year (2)
- Adult ITP: 1.6/100,000 per year (1)

Prevalence

Limited data; in one population (in Oklahoma) (3):

- Overall prevalence of 11.2/100,000 persons
- In children (<16 years): 8.1/100,000 with average age of 6 years
- In adults (>16 years): 12.1/100,000 persons with average age of 55 years

ETIOLOGY AND PATHOPHYSIOLOGY

- Accelerated platelet uptake and destruction by reticuloendothelial phagocytes results from action of IgG autoantibodies against platelet membrane glycoproteins IIb/IIIa. There is also cell-mediated platelet destruction by CD8+ T cells.
- Autoantibodies interfere with megakaryocyte maturation, resulting in decreased production.
- Fc-independent desialylated platelet clearance has been proposed as the mechanism of
refractoriness to therapies that target the classic FC-dependent pathway.

**RISK FACTORS**
- Autoimmune thrombocytopenia (e.g., Evans syndrome)
- Common variable immunodeficiency (CVID)
- Drug side effect (e.g., quinidine, vancomycin, penicillin, sulfonamides)
- Infections: Helicobacter pylori, hepatitis C, HIV, CMV, varicella zoster, measles, rubella, influenza, EBV, Whipple disease
- Vaccination side effect. Live virus vaccinations carry a lower risk than natural viral infection: 2.6/100,000 cases MMR vaccine doses versus 6 to 1,200/100,000 cases of natural rubella or measles infections.
- Bone marrow transplantation side effect
- Connective tissue disease, such as systemic lupus erythematosus, antiphospholipid antibody syndrome
- Lymphoproliferative disorders

**DIAGNOSIS**
A careful history, physical exam, and review of CBC and peripheral blood smear remain the key components of the diagnosis of ITP.

**HISTORY**
- Often asymptomatic; found incidentally on routine CBC
- Posttraumatic bleeding occurs at counts of 40 to 60 × 10⁹/L.
- With counts <30 × 10⁹/L, bruising tendency, epistaxis, menorrhagia, and gingival bleeding are common.
- Spontaneous bleeding may occur with platelet count <20 × 10⁹/L.
- Intracerebral bleeding is rare and may occur with counts <20 × 10⁹/L and associated trauma or vascular lesions, resulting in neurologic symptoms.
- Female sex and exposure to NSAIDs have been associated with bleeding.

**PHYSICAL EXAM**
- Ecchymoses, petechiae, epistaxis, and gingivorrhagia are common.
- Abnormal uterine bleeding may be present.
- Hemorrhagic bullae on buccal mucosa reflect acute, severe thrombocytopenia.
- Absence of splenomegaly, hepatomegaly, lymphadenopathy, stigmata of congenital disease

**DIFFERENTIAL DIAGNOSIS**
- Acute leukemia
- Thrombotic thrombocytopenic purpura
- Hemolytic uremic syndrome
- Factitious: platelet clumping on peripheral smear
- Thrombocytopenia secondary to sepsis
- Myelodysplastic syndrome, particularly in older patients
- Decreased marrow production: malignancy, drugs, viruses, megaloblastic anemia
- Posttransfusion
- Gestational thrombocytopenia
Isoimmune neonatal purpura
- Congenital thrombocytopenias
- Disseminated intravascular coagulation
- Alcohol-induced thrombocytopenic purpura

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- CBC with differential and peripheral smear:
  - Isolated decreased platelet count <100 × 10^9/L
  - Giant platelets are usually present.
  - Normal red and white blood cell morphology
- For patients with history, exam, CBC, and peripheral smear typical of ITP, consider the following:
  - PT/PTT is normal.
  - In adults, serologies for hepatitis B, hepatitis C, and HIV infections are recommended (1)[B].
  - In pediatric ITP, immunoglobulin levels to exclude CVID are commonly obtained (1)[B].
  - Other tests are not necessary for patients with typical ITP presentation: antiplatelet, antinuclear, antiphospholipid antibodies; H. pylori testing; thrombopoietin; platelet parameters; direct antiglobulin test; reticulocyte count; urinalysis; and thyroid function tests (1)[C].
- Further studies should be considered if the patient with thrombocytopenia also presents with:
  - Fever
  - Arthralgia
  - Lymphadenopathy
  - Family history of bleeding disorder
  - Risk factors for HIV
  - Abnormalities in other cell lines

**Diagnostic Procedures/Other**
- Imaging is not necessary.
- Bone marrow aspiration/biopsy
  - Not necessary for diagnosis in children (1)[B] and adults (1,2)[C]
  - Can be considered for a patient with atypical symptoms, such as fever and weight loss and multiple abnormalities in blood count

**Test Interpretation**
- Peripheral smear: normal red and white cells with large or giant platelets but diminished in number
- Marrow reveals normal to abundant megakaryocytes with normal erythroid and myeloid precursors.

**TREATMENT**

**GENERAL MEASURES**
- Management is based on both platelet count and hemorrhagic manifestations.
Current evidence-based guidelines recommend treatment should be administered for newly diagnosed patients with a platelet count $<30 \times 10^9$/L (1,2)[C].

The main goal is to achieve a platelet count associated with adequate hemostasis, rather than a normal count (1).

Outpatient management unless patient has platelet count $<20 \times 10^9$/L and is at risk for bleeding

Admit patients with active bleeding.

**MEDICATION**

**First Line**

- **Pediatric**
  - First-line treatment:
    - For children with no or mild bleeding (bruising and petechiae only with no mucosal bleeding), observation alone regardless of platelet count (1)[B]
    - For children with significant bleeding
      - Single-dose intravenous immunoglobulin (IVIG) 0.8 to 1.0 g/kg, especially when a more rapid increase in platelet count is desired (1)[B]. Do not administer in patients with IgA deficiencies because of anaphylaxis risk.
      - A short course of corticosteroids (e.g., PO prednisone 2 mg/kg/day for 2 weeks with 3 weeks taper) (1)[B]
      - Single dose of anti-Rho(D) immunoglobulin (anti-D), 50 to 75 g/kg for nonsplenectomized children who are Rh-positive, with negative direct antiglobulin test (1),(2)[B]. Do not use in children with low hemoglobin or evidence of hemolysis (1) [C].
    - Second and other treatments for pediatric and adolescent with ITP
      - Splenectomy for chronic or persistent ITP (1)[B]
        - Rituximab (Rituxan) 375 mg/m$^2$ weekly for 4 weeks (1,2)[C]
        - High-dose dexamethasone 0.6 mg/kg/day for 4 days every 4 weeks (1,2)[C]
        - Others without adequate data: azathioprine, cyclosporin A, danazol, mycophenolate mofetil, anti-CD52 monoclonal antibody, and interferon
        - Phase 3 clinical trials have shown that thrombopoietin receptor agonists induce good response in children with chronic ITP (4).

- **Adult**
  - First line, adult ITP
    - Treatment is recommended for newly diagnosed patients with platelet count $<30 \times 10^9$/L (1,2)[C].
    - Longer courses of steroids are preferred over shorter courses of steroids or IVIG (5).
    - If corticosteroids are contraindicated:
      - IVIG: 1 to 2 g/kg once, repeating as necessary (1,2)[C] OR
      - Anti-D: 50 to 75 μg/kg once, repeating as necessary for Rh+, nonsplenectomized patients. Do not use anti-D in patients with low hemoglobin or evidence of hemolysis (1,2)[C].
  - Second line, adult ITP
    - Splenectomy for patients who failed corticosteroid therapy (1)[B]
    - For patients for whom splenectomy is contraindicated and have risk of bleeding, thrombopoietin receptor agonists (1)[B]: eltrombopag (Promacta), 50 mg/day PO OR romiplostim (Nplate), 1 μg/kg SC weekly
Rituximab, 375 mg/m² IV weekly for 4 weeks, for patients at high risk of bleeding who have failed one line of therapy or postsplenectomy (1,2)[C]
- Others to consider: azathioprine, cyclosporine A, cyclophosphamide, danazol, dapsone, mycophenolate mofetil, and vincristine
- Asymptomatic patients after splenectomy, with platelet counts >30 × 10⁹/L, do not require treatment (1)[C].
- FDA has approved avatrombopag and fostamatinib recently.

- **ITP in pregnancy**
  - Preeclampsia or gestational thrombocytopenia may cause thrombocytopenia unrelated to ITP.
  - Corticosteroids or IVIG are considered safe and are considered first line (1)[C].
  - Do not use danazol or cyclophosphamide.
  - ITP management at time of delivery is based on maternal bleeding risks, and mode of delivery should be based on obstetric indications (1,2)[C]. Platelet autoantibodies can cross the placenta and cause neonatal thrombocytopenia.
  - Cesarean section can be considered if platelet count >50 × 10⁹/L.
  - Prednisone and/or IVIG may be considered 2 to 3 weeks prior to delivery.

- **ITP secondary to HIV**
  - Antivirals should be considered before other treatment (1)[A].
  - If treatment is required, corticosteroids, IVIG, or anti-D are first-line options, and splenectomy is a second-line option (1,2)[C].

- **ITP secondary to HCV**
  - Antivirals should be considered before other treatment (1,2)[C].
  - If treatment required, IVIG is initial treatment (1,2)[C].
  - Based on recent studies, TPO mimetics are approved for HCV-related ITP because they increase platelets to a level required to initiate antiviral therapy (6).

- **ITP and H. pylori**
  - Screen for H. pylori in patients in whom eradication therapy would be considered if result is positive (1,2)[C].

- **Emergency treatment**
  - Patients with intracranial or GI bleeding, massive hematuria, internal hematoma, or who need emergent surgery
    - IV corticosteroids (e.g., IV methylprednisolone, 1 g/day for 3 doses) (1)[B] with caution in patients with GI bleeding and/or IVIG 1 g/kg; repeat following day for count <50 × 10⁹/L (1)[B].
    - Platelet transfusions with IVIG may also be considered for significant bleeding (1)[C].
    - Other agents that may be considered: Recombinant factor VIIa (1)[C] not only promotes hemostasis but also increases risk of thrombosis. Efficacy of antifibrinolytic agents, aminocaproic acid and tranexamic acid, is unproved in randomized trials; they may be used as adjunctive treatments only. Emergent splenectomy has been reported.

**ISSUES FOR REFERRAL**
Hematology consultation is recommended for acute bleeding or for those who fail to respond to first-line therapies.

**SURGERY/OTHER PROCEDURES**
Splenectomy
Mortality rate is very low (<1%) even in patients with severe thrombocytopenia.

Necessary vaccinations prior to splenectomy: polyvalent pneumococcal vaccine and quadrivalent meningococcal vaccine every 3 to 5 years and one-time Haemophilus influenzae B (Hib)

Consider lifelong prophylactic antibiotics with penicillin or erythromycin.

Should raise the platelet count to at least 20 × 10^9/L prior to surgery

Reported 5- to 10-year efficacy is ~65% for all patients.

Laparoscopic splenectomy has similar long-term outcomes compared to open splenectomy and has better short-term outcomes in medically suitable patients (1)[C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Platelet counts weekly for patients on prednisone and monthly for stable patients are reasonable.

**DIET**

- Evidence demonstrating benefit of an anti-inflammatory diet in ITP is lacking.
- The following foods and supplements can cause significant bleeding: garlic, ginger, Ginkgo biloba, and saw palmetto.
- Some foods and supplements that may inhibit platelets: evening primrose oil, fish oil, feverfew, ginseng, licorice, soy, vitamin C, vitamin E, and wintergreen
- Partial list of foods and supplements with coumarin or salicylate components: alfalfa, angelica, anise, asafetida, aspen bark, birch, black cohosh, celery, chamomile, cinnamon, dandelion, fenugreek, heartsease, horse chestnut, meadowsweet, poplar, prickly ash, Quassia, sarsaparilla, sweet birch, sweet clover, and willow bark

**PATIENT EDUCATION**

- Modified activity to prevent injury or bruising; avoid contact sports.
- Avoid anticoagulants, aspirin and other platelet-inhibiting drugs, and NSAIDs.

**PROGNOSIS**

- Acute ITP
  - ~80–85% of patients completely recover within 2 months.
  - 15% proceed to chronic ITP.
- Chronic ITP
  - ~10–20% of the patients recover spontaneously.
  - Remainder with diminished platelets for months to years
  - May see spontaneous remissions (5%) and relapses
  - ~10% are refractory (fail medical therapy and splenectomy).

**COMPLICATIONS**

- Related to thrombocytopenia: 1% mortality due to intracranial hemorrhage and severe blood loss
- Related to treatment: for example, corticosteroid adverse effects, anaphylaxis and renal failure with IVIG, hepatotoxicity with eltrombopag, reports of progressive multifocal
leukoencephalopathy with rituximab, hemolysis with anti-D, and septicemia for splenectomized patients

REFERENCES

CODES

ICD10
D69.3 Immune thrombocytopenic purpura

CLINICAL PEARLS

- ITP: platelet counts of <100 × 10⁹/L caused by accelerated destruction and/or impaired thrombopoiesis by antiplatelet antibodies
- Pediatric ITP: relatively common, with spontaneous remission in 2 months
- Adult ITP: usually persistent; requires treatment, with rare spontaneous remission
- Goal of treatment is to achieve adequate hemostasis.
IMPETIGO
Elisabeth L. Backer, MD

BASICS

DESCRIPTION
- A contagious, superficial, intraepidermal infection occurring prominently on exposed areas of the face and extremities, most often seen in children
- Primary impetigo (pyoderma): invasion of previously normal skin
- Secondary impetigo (impetiginization): invasion at sites of minor trauma (abrasions, insect bites, underlying eczema)
- Infected patients usually have multiple lesions.
- Cultures are positive in >80% cases for Staphylococcus aureus either alone or combined with group A β-hemolytic streptococci; S. aureus is the more common pathogen since the 1990s.
- Nonbullous impetigo: most common form of impetigo. Formation of vesiculopustules that rupture, leading to crusting with a characteristic golden appearance; local lymphadenopathy may occur.
- Bullous impetigo: staphylococcal impetigo that progresses from small to large flaccid bullae (newborns/young children) caused by epidermolytic toxin release; ruptured bullae leaving brown crust; less lymphadenopathy; trunk more often affected; <30% of patients
- Folliculitis: considered by some to be S. aureus impetigo of hair follicles
- Ecthyma: a deeper, ulcerated impetigo infection often with lymphadenitis
- System(s) affected: skin/exocrine
- Synonym(s): pyoderma; impetigo contagiosa; impetigo vulgaris

EPIDEMIOLOGY

Incidence
- Predominant sex: male = female
- Predominant age: children ages 2 to 5 years

Prevalence
In the United States: not reported but common

Pediatric Considerations
- Poststreptococcal glomerulonephritis may follow impetigo (in young children).
- Impetigo neonatorum may occur due to nursery contamination.

ETIOLOGY AND PATHOPHYSIOLOGY
- Coagulase-positive staphylococci: pure culture ~50–90%; more contagious via contact
- β-Hemolytic streptococci: pure culture only ~10% of the time (primarily group A)
- Mixed infections of streptococci and staphylococci are common; data suggest increasing importance of staphylococci over the past decades.
- Methicillin-resistant S. aureus (MRSA) detected in some cases
- Direct contact or insect vector
- Can result from contamination at trauma site
- Regional lymphadenopathy
RISK FACTORS
- Warm, humid environment
- Tropical or subtropical climate
- Summer or fall season
- Minor trauma, insect bites, breaches in skin
- Poor hygiene, poverty, crowding, epidemics, wartime
- Familial spread
- Poor health with anemia and malnutrition
- Complication of pediculosis, scabies, chickenpox, eczema/atopic dermatitis
- Contact dermatitis (Rhus spp.)
- Burns
- Contact sports
- Children in daycare
- Carriage of group A Streptococcus and Staphylococcus aureus

GENERAL PREVENTION
- Close attention to family hygiene, particularly hand washing among children
- Covering of wounds
- Avoidance of crowding and sharing of personal items
- Treatment of atopic dermatitis

COMMONLY ASSOCIATED CONDITIONS
- Malnutrition and anemia
- Crowded living conditions
- Poor hygiene
- Neglected minor trauma
- Any chronic/underlying dermatitis
- Can occur as coinfection with scabies

DIAGNOSIS

HISTORY
- Lesions are often described as painful.
- May be slow and indolent or rapidly spreading
- Most frequent on face around mouth and nose or at site of trauma

PHYSICAL EXAM
- Tender red macules or papules as early lesions (contact dermatitis presents with pruritic lesions)
- Thin-roofed vesicles to bullae: usually nontender
- Pustules
- Weeping, shallow, red ulcers
- Honey-colored crusts
- Satellite lesions
- Often multiple sites
- Bullae on buttocks, trunk, face
DIFFERENTIAL DIAGNOSIS
- Nonbullous
  - Contact dermatitis
  - Chickenpox
  - Herpes
  - Folliculitis
  - Erysipelas
  - Insect bites
  - Severe eczematous dermatitis
  - Scabies
  - Tinea corporis
- Bullous
  - Burns
  - Pemphigus vulgaris
  - Bullous pemphigoid
- Stevens-Johnson syndrome

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- None usually necessary in typical presentations; cultures of pus/bullae fluid may be helpful if no response to empiric therapy.
  - Culture: taken from the base of lesion after removal of crust; will grow both staphylococci and group A streptococci
  - Antistreptolysin-O (ASO) titer: can be weak positive for streptococci but overall not useful
  - Antideoxyribonuclease B (anti-DNase B) and antihyaluronidase (AHT) response more reliable than ASO response
  - Streptozyme: positive for streptococci
- Disorders that may alter lab results: Streptococcal pharyngitis will alter streptococcal enzyme tests.

Follow-Up Tests & Special Considerations
- Monitor for spread of disease and systemic manifestations.
- Serologic testing is helpful in context of impetigo with subsequent poststreptococcal glomerulonephritis.

TREATMENT
GENERAL MEASURES
- Treatment speeds healing, improves cosmetic appearance, and avoids spread of disease.
- Prevent with mupirocin ointment TID to sites of minor skin trauma.
- Remove crusts; clean with gentle washing 2 to 3 times daily; and clean with antibacterial soap, chlorhexidine, or Betadine.
- Washing of entire body may prevent recurrence at distant sites.

MEDICATION
- In 2014, the Infectious Diseases Society of America (IDSA) recommended topical treatment
for limited lesions and oral medication when the disease is more severe/extensive (1)[A]. A 2017 Canadian systematic review found that topical mupirocin is equally, or more effective than oral treatments for nonextensive impetigo (2)[A]. Penicillin and macrolide therapy is no longer recommended. Fluoroquinolones are not indicated due to resistance patterns.

- Consult the local hospital or health department for microbial resistance information.
- Nonbullous (minor spread, treat 7 days; widespread, treat 10 days); bullous (treat 10 days)
  - Mupirocin (Bactroban) 2% topical ointment applied TID for 5 to 7 days (nonbullous only); not as effective on scalp as around mouth
  - Retapamulin 1% ointment to be applied BID for 5 days (very expensive)
  - Dicloxacillin: adult 250 mg PO QID; pediatric <40 kg: 12 to 25 mg/kg/day divided q6h; >40 kg: 125 to 250 q6h
- Dicloxacillin, cephalaxin, topical mupirocin, and fusidic acid are effective, unless local staphylococcal strains are resistant. For MRSA infections, treatment options include clindamycin, tetracyclines, or trimethoprim-sulfamethoxazole. Oral doses given for 7 days are usually sufficient (3)[C].
- 1st-generation cephalosporins
  - Children
    - Cephalexin 25 to 50 mg/kg/day divided, q6–12h
    - Cefaclor 20 to 40 mg/kg/day divided q8h
    - Cephradine 25 to 50 mg/kg/day divided q6–12h
    - Cefadroxil 30 mg/kg/day divided BID
  - Adults
    - Cephalexin 250 mg up to QID
    - Cefaclor 250 mg TID
    - Cephradine 500 mg BID
    - Cefadroxil 1 g/day in divided doses
- Clindamycin 300 mg q6–8h
- Severe bullous disease may require IV therapy such as nafcillin or cefazolin.

ISSUES FOR REFERRAL
If resistant or extensive infections occur, especially in immunocompromised patients

ADDITIONAL THERAPIES
Monitor for microbial resistance patterns.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Athletes are restricted from contact sports.
- School and daycare contagious restrictions
- Children can return to school 24 hours after initiation of antimicrobial treatment.

Patient Monitoring
If not clear within 7 to 10 days, culture the lesions.

PATIENT EDUCATION
Avoidance of infection spread is the key; hand washing is vital, especially for reducing spread in
children.

**PROGNOSIS**
- Complete resolution in 7 to 10 days with treatment
- Antibiotic treatment will not prevent or halt glomerulonephritis, as it will in rheumatic fever.
- If not clear within 7 to 10 days, culture is necessary to find resistant organism.
- Recurrent impetigo: Evaluate for carriage of S. aureus in nares (also perineum, axillae, toe web). Apply mupirocin ointment to nares BID for 5 days for decolonization.

**COMPLICATIONS**
- Ecthyma
- Erysipelas
- Poststreptococcal acute glomerulonephritis
- Cellulitis
- Bacteremia
- Osteomyelitis
- Septic arthritis
- Pneumonia
- Lymphadenitis

Algorithm: Rash

CODES

ICD10
- L01.00 Impetigo, unspecified
- L01.01 Non-bullous impetigo
- L01.03 Bullous impetigo

CLINICAL PEARLS
- Superficial, intraepidermal infection
- Predominantly staphylococcal in origin
- Microbial resistance patterns need to be monitored.
- Topical treatment is recommended for limited lesions and oral medication only when the disease is more severe/extensive.
BASICS
Continuous or recurrent involuntary passage of fecal material through the anal canal for >1 month in an individual at least 4 years of age
- Involves recurrent, involuntary loss of solid/liquid stool
- Requires careful rectal exam to assess rectal tone, voluntary squeeze, and rule out overflow incontinence from fecal impaction
- Endorectal ultrasound (EUS) is the simplest, most reliable, and least invasive method to detect anatomic anal sphincter defects.
- The goal of treatment is to restore continence and/or improve quality of life.

DESCRIPTION
Major incontinence is the involuntary evacuation of feces. Minor incontinence (fecal soilage) includes incontinence to flatus and occasional seepage of liquid stool.

Geriatric Considerations
- The prevalence of fecal incontinence increases with age. It is an important cause for nursing home placement among the elderly.
- Idiopathic fecal incontinence is more common in older women.

EPIDEMIOLOGY
Incidence
Patients often do not report fecal incontinence unless specifically queried (“silent affliction”). The number of affected patients is likely significantly underestimated.

Prevalence
- Women > men
- 7% of adults; 15% of adults age >90 years
- 56–66% of hospitalized older patients and >50% of nursing home residents
- 50–70% of patients who have urinary incontinence also suffer from fecal incontinence.

Pregnancy Considerations
Obstetric injury to the pelvic floor may result in either temporary or persistent incontinence.

Geriatric Considerations
- Fecal impaction and overflow diarrhea leading to fecal incontinence is common in older patients.
- Surgical history—particularly anal surgery, including hemorrhoidectomy, anal fissure repair (sphincterotomy), anal dilatation, or prior pelvic floor surgeries

ETIOLOGY AND PATHOPHYSIOLOGY
- Continence requires the complex orchestration of pelvic musculature, nerves, and reflex arcs.
- Stool volume and consistency, colonic transit time, anorectal sensation, rectal compliance, anorectal reflexes, external and internal sphincter muscle tone, puborectalis muscle function,
and mental capacity each plays a role in maintaining fecal continence.

- Disease processes or structural defects impacting any of these factors may contribute to incontinence.
- Diabetes is the most common metabolic disorder leading to fecal incontinence through pudendal nerve neuropathy.
- Congenital: spina bifida and myelomeningocele with spinal cord damage
- Trauma: anal sphincter damage from vaginal delivery or surgical procedures
- Medical: diabetes mellitus, stroke, spinal cord trauma, degenerative disorders of the nervous system, inflammatory bowel disorders, rectal neoplasia

**RISK FACTORS**

- Poor functional status—older age, female sex, obesity, limited physical activity contributory
- Neuropsychiatric conditions (dementia, depression)
- Multiple sclerosis, spinal cord injury, stroke, diabetic neuropathy
- Prostatectomy, radiation
- Trauma: Risk factors for perineal trauma at the time of vaginal delivery include occipitoposterior presentation, prolonged second stage of labor, assisted vaginal delivery (forceps or vacuum-assist), and episiotomy.
- Diarrhea, inflammatory bowel disease (IBD), irritable bowel syndrome (IBS), menopause, smoking, constipation
- Potential association with child abuse and sexual abuse
- Congenital abnormalities, such as imperforate anus/rectal prolapse
- Fecal impaction

**GENERAL PREVENTION**

- Behavioral and lifestyle changes: Obesity, limited physical activity/exercise, poor diet, and smoking are modifiable risk factors.
- Postmeal bowel regimen—defecate regularly after meals to maximize effect of gastrocolic reflex.
- Pelvic floor muscle training during and after pregnancy and pelvic surgery
- Increase fiber intake (>30 g/day)

**COMMONLY ASSOCIATED CONDITIONS**

- Increasing age (>65 years)
- Urinary incontinence/pelvic organ prolapse
- Chronic medical conditions—diabetes mellitus, dementia, stroke, spinal cord compression, depression, immobility, chronic obstructive pulmonary disease, IBS, and IBD
- Perineal trauma (obstetric)
- Anorectal surgery
- History of pelvic/rectal irradiation

**DIAGNOSIS**

Diagnosis is based on history and physical findings.

**HISTORY**

- Patients seldom volunteer information about fecal incontinence. Direct questioning is
Problem-specific history includes (1)[C]:
- Severity of soiling by liquid stool or gross incontinence of solid stool
- Onset and duration (recent onset vs. chronic)
- Frequency, presence of constipation/diarrhea
- Medication review
- Review diet, medical and obstetric history, lifestyle, and mobility.
- Evaluate for social withdrawal and depression.

PHYSICAL EXAM
- Inspect the perineum for chemical dermatitis, hemorrhoids, fistula, surgical scars, skin tags, rectal prolapse, soiling, and ballooning of the perineum (sarcopenia of pelvic musculature).
- A patulous anal orifice may indicate myopathy or a neurologic disorder.
- Evaluate the external sphincter response to perineal skin stimulation (anal wink). Absence suggests neuropathy.
- Ask the patient to bear down, preferably in standing position, to assess for rectal prolapse.
- Digital rectal exam to assess anal canal pressure sphincter tone, rectal bleeding, hemorrhoids, neoplasm, fecal consistency, and diarrhea/distal fecal impaction
- General neurologic examination, including perianal sensation (1)[C]
- Evaluate mental status.

DIFFERENTIAL DIAGNOSIS
- Anorectal disorders
  - Inflammatory/infectious gastrointestinal disorders
  - Bowel neoplasms, radiation proctitis, ischemic colitis, fistulas
  - Prolapsed internal hemorrhoids; rectal prolapse
  - Trauma: obstetric, surgical, radiation, accidental, sexual
- Neurologic disorders
  - Stroke, dementia, neoplasms, spinal cord injury, and/or diseases causing altered level of consciousness
  - Pudendal neuropathy, neurosyphilis, multiple sclerosis, diabetes mellitus
- Miscellaneous causes
  - Infectious diarrhea, fecal impaction and overflow, IBS, laxative abuse, IBD, short bowel syndrome, myopathies, senescence and frailty, collagen vascular disease, psychological and behavioral problems

DIAGNOSTIC TESTS & INTERPRETATION
The approach to fecal incontinence in older patients should be individualized, minimally invasive, and practically feasible. History and physical examination are generally sufficient for diagnosis. If uncertainty remains, consider the following:
- EUS is the most reliable and least invasive test for defining anatomic defects in the external and internal anal sphincters, rectal wall, and the puborectalis muscle (1)[B]. EUS can reliably predict therapeutic response to sphincteroplasty.
- Plain abdominal x-ray (fecal impaction, constipation)
- Sigmoidoscopy/anoscopy/colonoscopy (hemorrhoids, colitis, neoplasm)

Initial Tests (lab, imaging)
- If history of travel, antibiotics, tube feedings, or signs and symptoms of sepsis, consider stool
studies:
  – Culture
  – Ova and parasites
  – Clostridium difficile toxin assay

• Thyroid-stimulating hormone (TSH), electrolytes, and blood urea nitrogen in elderly patients
• EUS may demonstrate structural abnormalities of the anal sphincters, rectal wall, or puborectalis muscle.
• EUS may detect a sphincter injury in over 1/3 of primiparous vaginal deliveries and nearly half of multiparous vaginal deliveries.

Follow-Up Tests & Special Considerations
• Defecography can measure the anorectal angle, evaluate pelvic descent, and detect occult/overt rectal prolapse.
• MRI defecography (dynamic MRI) can further define pelvic floor anatomy.
• Anorectal manometry measures parameters such as maximal resting anal pressure, amplitude and duration of squeeze pressure, the rectoanal inhibitory reflex, threshold of conscious rectal sensation, rectal compliance, and anorectal pressures during straining.
• Pudendal nerve terminal motor latency (PNTML) measures neuromuscular integrity between the pudendal nerve and the anal sphincter, is operator-dependent, and has poor correlation with clinical and histologic findings
• Electromyography can assess neurogenic/myopathic damage.

TREATMENT

GENERAL MEASURES
• In ambulatory patients, scheduled (or prompted) defecation is effective, particularly in those with overflow incontinence.
• Kegel exercises to strengthen pelvic floor
• If bed-bound, scheduled osmotic or stimulant laxatives for constipation
• Enemas, laxatives, and suppositories may help promote more complete bowel emptying in impacted patients and minimize postdefecation leakage.
• Use of stool deodorants (Peri-Wash, Derifil, Devrom)

MEDICATION

Limited evidence that antidiarrheals (loperamide, codeine) and drugs enhancing sphincter tone (phenylephrine gel, sodium valproate) are of benefit (2)[B]. Cholestyramine, colestipol useful in diarrhea following malabsorption or cholecystectomy; alosetron in diarrhea due to IBS, amitriptyline in idiopathic fecal incontinence

First Line
Specific treatment of underlying disorder (e.g., infectious diarrhea/IBD) may improve fecal continence.

Second Line
• Increasing dietary fiber in milder forms of fecal incontinence reduces symptoms (1)[B]. Stool-bulking agents include high-fiber diet, psyllium products, or methylcellulose.
• Antidiarrheal agents, such as adsorbents or opium derivatives, may reduce diarrhea-associated
Disimpacting patients with fecal impaction and overflow incontinence and treating with a bowel regimen to prevent recurrence

ADDITIONAL THERAPIES

- Biofeedback: initial treatment modality in motivated patients with some voluntary sphincter control (1)[C]; teaches patients to recognize rectal distension and contract the external anal sphincter while keeping intra-abdominal pressure low.
- Biofeedback plus electrical stimulation of the anal sphincters is more effective than either alone.
- Patients with systemic neurologic disorders, anal deformities, or frequent episodes of incontinence respond poorly.

SURGERY/OTHER PROCEDURES

- Surgery should be considered only when nonsurgical approaches have failed.
- Sphincter repair should be offered for highly symptomatic patients with well-defined defect of external anal sphincter (1)[A].
- Injectable therapy (tissue-bulking agent injected into the anorectal submucosa or the intersphincteric space) appears safe and effective (40% efficacy) for patients with internal anal sphincter dysfunction (3)[A].
- Artificial anal sphincter implantation/dynamic graciloplasty (where gracilis muscle transposed into anus as modified sphincter) considered in patients with severe fecal incontinence and irreparable sphincter damage (4)[B]
- Stoma (colostomy/ileostomy) creation may be appropriate in patients with disabling fecal incontinence when other available therapeutic options have failed or if preferred by patient (1) [B]. A continent stoma created using the appendix or the cecum as the point of entry is a less radical option and enables using antegrade continence enema to flush the colon in these patients.
- Anal plugs minimize fecal leakage in patients who do not benefit from other treatment modalities, especially immobilized, institutionalized, or neurologically disabled patients; plugs often poorly tolerated (1)[C]
- Sacral nerve stimulation (neuromodulation) via implantation of SC electrodes delivering low-amplitude electrical stimulation to sphincter muscles improves overall rectal tone, especially in patients with a coexistent sphincter defect (5)[B].
- SECCA procedure (radiofrequency anal sphincter remodeling)—temperature-controlled radiofrequency energy delivered to the anorectal junction distal to the dentate line causing tissue damage, scarring, and anal canal narrowing. Minimally invasive, ambulatory procedure useful in mild-to-moderate fecal incontinence (1)[C].
- Magnetic anal sphincter (MAS) devices—series of interlinked titanium beads (14 to 20) with internal magnetic cores placed to form a flexible ring that encircles the external anal sphincter 3 to 5 cm from the anal verge. During expulsion of feces, the beads separate allowing evacuation. After evacuation, the beads approximate closing the canal (5)[C]; useful in moderate and severe incontinence.
- A vaginally placed bowel control device that the patient inflates to control leakage and deflates to defecate is well tolerated and effective in 86% (5)[B].
- Percutaneous posterior tibial nerve stimulation at the ankle for 30 minutes weekly for 12 weeks (50% efficacy) and the TOPAS pelvic floor repair system (self-fixating polypropylene
mesh placed behind the anorectum to support the puborectalis) (55% efficacy) are other recent advances in controlling fecal incontinence (5)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- If secondary to fecal impaction, manual evacuation of fecal mass (after lubrication with lidocaine jelly)
- Avoid catharsis.
- No hot water, soap, or hydrogen peroxide enemas
- Outpatient care

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Periodic rectal exam

**Patient Monitoring**
Consider impaction if there is <1 bowel movement every other day in patients with fecal incontinence.

**DIET**
- High fiber (20 to 30 g/day) and at least 1.5 L fluid daily
- Avoid precipitants (caffeine).

**PATIENT EDUCATION**
Kegel/sphincter training exercises are helpful but not sufficient for treating fecal incontinence.

**PROGNOSIS**
- Reimpaction likely if bowel regimen discontinued
- 50% failure rate over 5 years following overlapping sphincteroplasty

**COMPLICATIONS**
- Depression and social isolation
- Skin ulcerations
- Artificial bowel sphincter: infection, erosion, mechanical failure

**REFERENCES**
ADDITIONAL READING

Menees SB. My approach to fecal incontinence: it’s all about consistency (stool, that is). Am J Gastroenterol. 2017;112(7):977–980.

CODES

ICD10

- R15.9 Full incontinence of feces
- R15.2 Fecal urgency
- R15.0 Incomplete defecation

CLINICAL PEARLS

- Scheduled defecation after meals, bulking agents, and scheduled enemas minimize impaction and are helpful in mild/moderate fecal incontinence.
- Differentiate true incontinence from pseudoincontinence (overflow or functional incontinence).
- New onset fecal incontinence may indicate spinal cord compression if accompanied by other neurologic signs or symptoms.
INCONTINENCE, URINARY ADULT FEMALE
Mariya Milko, DO, MS

BASICS

DESCRIPTION

● Urinary incontinence: involuntary loss of urine
● Stress incontinence: associated with increased intra-abdominal pressure, such as coughing, laughing, sneezing, or exertion
● Urge incontinence: sudden uncontrollable loss of urine, preceded or accompanied by urgency, or a sudden compelling desire to urinate that is difficult to delay. Urge incontinence may be associated with overactive bladder or detrusor overactivity.
● Mixed incontinence: loss of urine from a combination of stress and urge incontinence
● Overflow incontinence: high residual or chronic urinary retention leading to urinary spillage from an overdistended bladder
● Functional incontinence: loss of urine due to deficits of cognition and/or mobility
● Total incontinence: continuous leakage of urine; leakage without awareness

EPIDEMIOLOGY

● Overall prevalence—38% of women age >60 years. A 2012 survey showed stress incontinence affected 37.5% of women age 30 to 50 years (1).
● Prevalence in women >75 years is 75%, and 6% of nursing home admissions are directly attributable to incontinence (2).

ETIOLOGY AND PATHOPHYSIOLOGY

● Stress incontinence: occurs with increased intra-abdominal pressure. Two types:
  – Anatomic: due to urethral hypermobility from lack of pelvic support
  – Intrinsic sphincter deficiency (ISD): impaired closure of urethra. Urethral mucosal seal and inherent closure from collagen, fibroelastic tissue, and smooth and striated muscles may be lost secondary to surgical scarring, radiation, or hormonal and age-related changes.
● Urge incontinence: may be due to detrusor overactivity or may be idiopathic
● Overflow incontinence: urinary retention (usually from neurogenic bladder)
● Total incontinence: constant loss of urine. Ectopic ureters in females usually open in the urethra distal to the sphincter or in the vagina, causing continuous leakage; may also occur with fistulous connections between bladder, ureters, or urethra and vagina or uterus
● Women with urge urinary incontinence report poorer quality of life than those with stress incontinence (2).

RISK FACTORS

Advanced age, impaired functional status, obesity (BMI >30), history of gestational diabetes, pregnancy, vaginal childbirth, pelvic surgery or radiation, urethral diverticula, genital prolapse, smoking, chronic obstructive pulmonary disease (COPD), cognitive impairment, constipation, caffeine, and pelvic floor dysfunction

GENERAL PREVENTION

Obesity and caffeine avoidance, smoking cessation, high-fiber diet to reduce constipation
COMMONLY ASSOCIATED CONDITIONS
Pelvic organ prolapse, urinary tract infection (UTI), COPD, diabetes mellitus, neurologic disease, obesity, chronic constipation, depression, low libido, dyspareunia, and any disease that results in chronic cough

DIAGNOSIS

HISTORY
- Important to screen for symptoms because only 45% of women who reported at least twice weekly urine leakage on a U.S. survey sought care for their symptoms (2)
- Age: Stress incontinence is more common in women aged 19 to 64 years, whereas mixed incontinence is more common in women >65 years. Onset from childhood indicates congenital causes (e.g., ectopic ureter).
- Amount and frequency of leakage; pad usage
- Stress incontinence: occurs in small spurts; patients typically remain dry at night in bed.
- Urge incontinence: sudden urge followed by leakage of large amounts, usually associated with frequency and nocturia. Sensory stimuli may trigger (e.g., cold).
- Continuous slow leakage in between regular voiding indicates ectopic ureter or urinary fistula.
- Pain: Suprapubic pain with dysuria implies urinary infection or interstitial cystitis.
- Medical history
  - Neurologic conditions or suggestive symptomatology: cerebrovascular accident, parkinsonism, multiple sclerosis, myelodysplasia, diabetes, spinal cord injury
  - Radiation to pelvic and vaginal areas: causes ISD, overactive bladder, fibrotic changes of pelvic floor musculature, and low bladder compliance
  - Obstetric history: Weakness of the pelvic floor is more likely in multiparous women.
  - History of smoking and COPD with a chronic cough can aggravate incontinence.
  - Constipation can aggravate incontinence.
  - Surgical history: Pelvic surgery, including gynecologic and bowel surgery, can injure the pelvic floor musculature and affect neurologic function.
- Medications
  - Sympatholytic α-blockers (terazosin, prazosin, doxazosin, tamsulosin, alfuzosin, silodosin) can cause or worsen incontinence.
  - Sympathomimetic agents, tricyclic antidepressants, anticholinergics, and opioids can cause retention with overflow incontinence.
- International Consultation on Incontinence Questionnaire (ICIQ) is highly recommended for assessment of patient’s perspective of symptoms of incontinence and his or her impact on quality of life.
- Can use 3-day voiding diary to evaluate fluid intake, caffeine intake, timing of leakage, and patient habits

PHYSICAL EXAM
- General status
  - Obesity (BMI)
- General neurologic examination
  - Mental status, speech, intellectual performance
  - Motor status: gait, generalized or focal weakness, rigidity, tremor
Urologic examination
- Abdomen: masses, incisional scars of previous surgeries
- Suprapubic tenderness: may indicate cystitis
- Palpable, distended bladder: chronic urinary retention

Pelvic examination
- Examination of the perineum and external genitalia, including tissue quality and sensation
- Vaginal (half-speculum) examination for prolapse
- Bimanual pelvic and anorectal examination for pelvic masses, fecal impaction, pelvic floor function, and so forth
  - Assessment of pelvic floor resting tone and function (ability to isolate and contract pelvic floor musculature) (3); can use Oxford scale to grade strength
- Urethral mobility (cotton swab test): displacement angle of urethra-bladder neck at least 30 degrees from horizontal with Valsalva (2)
- Stress test: positive with involuntary loss of urine from urethral meatus with cough or Valsalva maneuver. If test is negative in supine position, can try in standing position. Ensure that patient has a comfortably full bladder (4). Test has 98% positive predictive value for SUI (3).
- Cystocele: if evident, should stage (grade 0 to 4)
- Rectocele: if evident, should stage (stage 0 to 4)

DIFFERENTIAL DIAGNOSIS
- Nocturnal enuresis: idiopathic, detrusor overactivity, neurogenic, cardiogenic, or sleep apnea
- Continuous leakage: ectopic ureter, urinary fistulas
- Postvoid dribbling: urethral diverticulum, idiopathic, iatrogenic, surgical
- Pelvic pain/dyspareunia: interstitial cystitis, sexually transmitted infection (STI)
- Pelvic organ prolapse
- Hematuria/recurrent UTI/pelvic mass: malignancy

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Urinalysis and urine culture
- Renal function assessment: recommended if renal impairment is suspected
- Imaging is unnecessary in uncomplicated patients.
- Bladder scan to evaluate postvoid residual (PVR) if overflow suspected (>100 mL) (5)
- TSH if constipation is present
- Upper tract imaging if upper tract involvement is suspected: renal ultrasound

Follow-Up Tests & Special Considerations
With a positive urine culture, initial treatment is reasonable. However, treatment of asymptomatic bacteriuria will not improve UI in the elderly (5)[B].

Diagnostic Procedures/Other
- Urodynamic studies and cystoscopy are not indicated in initial workup and should only be performed after failing conservative treatment; this includes cystometric study of detrusor function and pressure flow studies looking at bladder emptying (1,5)[B].
- Cystoscopy should be performed in women with microscopic hematuria and may be helpful in
evaluating recurrent UTIs (3).
- Results of urodynamic testing are not predictive of treatment success (2)[A] and are not necessary prior to surgery for uncomplicated patients with known SUI (3)[C].

**TREATMENT**

**GENERAL MEASURES**
- Treat correctable causes (e.g., UTI).
- Encourage weight loss in obese patients.
- Aggressively correct constipation.
- Treat mixed for primary symptom type (5)[C].

**MEDICATION**

**First Line**
- **Lifestyle changes:**
  - Reduce BMI to <25; can reduce weekly incontinence episodes by 28–47% (2)[A]. Even moderate weight loss (5–10%) can help (6)[A].
  - Bladder diaries (fluid intake, voids, leakage)
  - Decrease fluid intake before bedtime.
  - Reduce caffeine to <1 cup coffee per day (2)[B].
  - Aggressive treatment of constipation: Limit medications that may induce constipation. Treat constipation with polyethylene glycol 3350 (PEG 3350), increased fluid intake, and nutrition (5)[C].
  - Smoking cessation is strongly recommended. Urgency and frequency are 3x more common among current smokers compared to never smokers (7)[A].
- Pelvic floor muscle training with Kegel exercises may be used alone or in combination with bladder training, biofeedback, or electrical stimulation (2).
  - Proper technique should be confirmed on exam by trained physical therapists. Recommend 3 sets of 10 contractions held for 10 seconds each (1)[C].
  - Women who undergo pelvic floor muscle training are 8 times more likely to report cure than with no treatment (6)[A].
- **Bladder training:**
  - Scheduled voiding, urge suppression between voids
- No differences in treatment efficacy by type of incontinence, so reasonable to start with lifestyle changes in all types (2)[A]

**Second Line**
- Stress incontinence
  - Duloxetine (Cymbalta) 40 mg is effective but causes GI and central nervous system side effects; no differences between SUI and MUI (5)[A]
  - Estrogen may be beneficial in topical form for symptoms of urgency and frequency in postmenopausal women with vaginal atrophy, but transdermal or PO estrogen may worsen symptoms (1)[B],(2)[C].
  - Surgical management for stress incontinence
    - Mesh midurethral sling (most common, most studied surgical intervention) (2)[C],(4)[A]
    - Women with moderate to severe stress incontinence have better outcomes at 1 year with
midurethral slings than pelvic floor muscle training (2)[A].

- Main approaches with similar effectiveness: retropubic (more perioperative complications) versus transobturator (more groin pain) (2,4)[A]

- Autologous fascial bladder neck slings should be considered in severe incontinence and fixed urethra, urethral diverticula or fistula, or with complications from previously placed mesh (2)[C].

- Pelvic organ prolapse may unmask incontinence in up to 40% of women; consider repair of both during same surgery (2)[A].

- Periurethral bulking agents (silicone polymers, collagen) can increase periurethral resistance in women who have recurrent symptoms after surgery or who cannot tolerate surgery. However, they are 2 to 5 times less effective than surgery and often require repeat injections (2)[A].

- Occlusive and supportive devices (e.g., cones, pessaries) are a low risk alternative to surgery (4,5,6)[C].

**Urge incontinence: anticholinergic agents (inhibit involuntary detrusor contractions) (1)[A]**

- Tolterodine (Detrol LA): 2 to 4 mg/day PO
- Oxybutynin (Ditropan XL): 5 to 15 mg/day PO
- Solifenacin (VESIcare): 5 to 10 mg/day PO
- Darifenacin (Enablex): 7.5 to 15.0 mg/day PO
- Trospium chloride (Sanctura XR): 20 to 60 mg/day PO—does not cross blood–brain barrier (3)
- Transdermal oxybutynin gel (Gelnique): 10%, 1 g applied daily
- Transdermal oxybutynin patch (Oxytrol): twice weekly—available over the counter (OTC)
- Fesoterodine (Toviaz): 4 to 8 mg/day PO

- Fesoterodine may be more effective than tolterodine, at the expense of greater adverse effects (1)[B].

- No single agent has been shown to be overall superior (5).
- Extended-release and transdermal medications cause fewer side effects (1)[C].
- Dry mouth, dry eyes, constipation, impaired cognitive function, and other anticholinergic side effects can limit use.

- Higher doses are more effective but have higher risk of side effects (4)[B].
- Avoid with narrow-angle glaucoma, urinary retention (PVR >250 mL), impaired gastric emptying, frail elders (3); may worsen existing cardiac arrhythmias (1)

**Third Line**

- Stress incontinence
  - Acupuncture (1)[B]

- Urge incontinence
  - Intradetrusor onabotulinumtoxinA 100 to 200 U (urinary retention common, temporary selfcatheterization may be needed) (5)[A]
  - Sacral nerve stimulation: 61% of patients found this treatment effective and efficacy maintained at mean 30 months; invasive with frequent complications (3)[B]
  - Posterior tibial nerve stimulation: office-based therapy, requires frequent visits (3)[B]
  - Bladder augmentation: At average 6-year follow-up, only 53% were continent (5)[B].

**Geriatric Considerations**

- Anticholinergics (oxybutynin, in particular) can worsen cognition and delirium; the effects are
cumulative and increase with length of exposure (5).

- $\beta_3$ Agonist (leads to detrusor muscle relaxation and increased bladder capacity): mirabegron (Myrbetriq ER): 25 to 50 mg/day PO (1)[B]; onset of action delayed ~8 weeks; increases BP (avoid use in those with uncontrolled hypertension, end-stage renal disease, or significant liver impairment); safe in geriatric patients (5); recommend BP check 2 weeks after starting (3)[C].

- Can consider dual therapy with mirabegron and low-dose anticholinergics (3,5)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Periodic long-term follow-up with outcome-based questionnaire surveys

**PATIENT EDUCATION**

**PROGNOSIS**

Significant improvements are usually obtained with most patients.

**COMPLICATIONS**

- Prolonged exposure to urine causes skin breakdown and dermatitis, which may lead to ulceration and secondary infection.
- Inability to self-care (including toileting) is the precipitating factor for many nursing home admissions.
- Increased risk for falls
- Social isolation/depression
- Weight gain (due to self-limiting exercise from fear of leakage)
- Impaired sexual function
- Impaired quality of life

**REFERENCES**

ADDITIONAL READING

CODES

ICD10

- R32 Unspecified urinary incontinence
- N39.3 Stress incontinence (female) (male)
- N39.41 Urge incontinence

CLINICAL PEARLS

- Rule out infection (UTI or STI) and hematuria.
- Aggressively treat constipation.
- Try lifestyle changes first for all types of urinary incontinence.
- If lifestyle changes do not work for stress incontinence, mesh midurethral sling surgery has high success rates.
- If lifestyles changes do not work for urge incontinence, anticholinergic medications, and/or mirabegron should be trialed.
INCONTINENCE, URINARY ADULT MALE
William Dabbs, MD • Justin Jenkins, DO, MBA • Taylor Wright, MD

BASICS

DESCRIPTION
- Urinary incontinence (UI) is a pathologic condition of an acute or chronic nature that refers to the involuntary loss of urine leading to medical, financial, social, or hygienic problems. Five main types of UI have been described: stress, urge, mixed, overflow (urinary retention), and functional UI (1).
- Stress incontinence: involuntary urine leaks secondary to increased intra-abdominal pressure being greater than the sphincter can control; may be precipitated by sneezing, laughing, coughing, exertion.
- Urge incontinence: Involuntary leakage of urine associated with urgency is believed to be secondary to uncontrolled contraction of the urinary bladder. It is also called detrusor overactivity.
- Mixed incontinence: involuntary leakage of urine with urgency and with stress, such as sneezing, laughing, coughing, exertion.
- Overflow incontinence: also known as urinary retention; this occurs with bladder overdistention due to impaired detrusor contraction or bladder outlet obstruction (due to benign prostatic hyperplasia [BPH], bladder stones, bladder tumors, pelvic tumors, urethral strictures, or spasms).
- Functional UI: urine leakage variable, often due to environmental or physical barriers to toileting (i.e., reduced mobility)
- Polyuria is defined by excessive amounts of urine (≥2.5 to 3.0 L) >24 hours.
- Nocturnal polyuria is where >33% of total daily urine output occurs during sleeping hours.

EPIDEMIOLOGY
- Stress incontinence in men is rare and is often attributable to prostate surgery, neurologic disease, or trauma.
- Involuntary detrusor overactivity may be spontaneous or provoked and may be neurogenic or idiopathic in cause.
- Reported rates of incontinence range from 1% after transurethral resection to 2–66% after radical prostatectomy and 1–15% following transvesical prostatectomy, although rates decline with time (1).

Prevalence
- 12.4% prevalence of UI in community-dwelling adult men in the United States as based on the National Health and Nutrition Examination Survey (NHANES) as of 2008
- 4.5% reported moderate to severe UI, of which 48.6% experienced urge, 23.5% experienced other UI, 15.4% experienced mixed, and 12.5% experienced stress incontinence as per the NHANES report in 2010.
- UI is common in nursing home patients, with a prevalence of about 70% in the Southeastern United States from 1999 to 2002.
- Incontinence in men of all ages is approximately half as prevalent as it is in women; however,
after 80 years of age, both sexes are affected equally (1).

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Incontinence secondary to bladder abnormalities
  - Detrusor overactivity results in urge incontinence.
  - Detrusor overactivity commonly is associated with bladder outlet obstruction from BPH.
- Incontinence secondary to outlet abnormalities
  - Sphincteric damage secondary to pelvic surgery or radiation
  - Sphincteric dysfunction secondary to neurologic disease
  - Commonly associated with BPH due to compression of the urethra, affecting urinary flow
- Mixed incontinence is caused by abnormalities of both the bladder and the outlet overflow or by enlarged prostate/bladder neck contracture from prostate surgery.
- Stress incontinence is caused by weakened urethral sphincter and/or pelvic floor weakness.

**RISK FACTORS**

- Age
- Diabetes
- Hypertension (HTN)
- History of urinary tract infections
- Major depression
- Neurologic disease
- Pelvic trauma
- Polypharmacy
- Prostate surgery

**GENERAL PREVENTION**

Proper management of conditions, such as symptomatic bladder outlet obstruction caused by BPH early in the course, may prevent continence problems later in life; no evidence for screening in men unless patient is experiencing symptoms using the 3 Incontinence Questions tool to evaluate the type of UI (2).

**COMMONLY ASSOCIATED CONDITIONS**

- Benign prostatic hypertrophy
- Neurologic disease (cerebrovascular accident, parkinsonism, multiple sclerosis, myelodyplasia, spinal cord injury, normal pressure hydrocephalus, and cognitive impairment)
- Major depression
- Pelvic surgery, radiation, or trauma

**DIAGNOSIS**

**HISTORY**

- Voiding symptoms
  - Duration and characteristics of incontinence
  - Precipitants, severity, timing, and associated symptoms (BPH, fluid intake, etc.)
  - Use of pads, briefs, diapers
  - Alteration in bowel habits
  - Previous treatments and effect on incontinence
Associated conditions, such as diabetes mellitus, neurologic disease, cardiopulmonary disorders, renal disorders, sleep disturbance, mental health or cognitive impairment, erectile dysfunction

Transient causes: UTI, delirium, medications, constipation, immobility

Geriatric patients: Assess cognitive levels (dementia/delirium), psychological disorders, mobility problems.

Medication use: diuretics, drugs for BPH, opioids, muscle relaxants, anticholinergics, antidepressants

Alcohol and drug use, including caffeine

Surgery
- Pelvic surgery or radiation
- Bowel, back, genitourinary procedures
- Abdominoperineal resection
- Prostatectomy: radical for cancer, open/transurethral for benign disease

Red flag symptoms requiring rapid referral to specialist management
- Pain, hematuria, recurrent UTI, history of prostate irradiation, history of radical pelvic surgery (i.e., prostate surgery), constant leakage suggesting fistula, voiding difficulty, suspected neurologic disease

**PHYSICAL EXAM**

- Cardiovascular
  - Look for signs of volume overload.
- Abdominal examination
  - Suprapubic mass suggests retention.
  - Suprapubic tenderness suggests UTI.
  - Surgical scars suggesting prior pelvic surgery
  - Skin lesions associated with neurologic disease (e.g., neurofibromatosis and café au lait spots)
- Genitourinary examination
  - External genitalia
  - DRE (prostate)
- Musculoskeletal (look for neurogenic or functional causes)
  - Extremities and spine
  - Skeletal deformities
  - Scars from previous spinal surgery
  - Sacral abnormalities may be associated with neurogenic bladder dysfunction.
- Neurologic
  - Motor, sensory, reflexes

**DIFFERENTIAL DIAGNOSIS**

- Transient (infections, meds, constipation, etc.)
- Chronic
  - Urge incontinence
  - Stress incontinence
  - Mixed incontinence
  - Overflow incontinence
  - Functional UI
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Urinalysis and urine culture to check for glucosuria, pyuria, proteinuria, and/or blood
  - If UTI is present, treat and then reassess need for further workup as this frequently causes UI (3)[C]
- Voiding diary, the 3 Incontinence Questions (1)[C]
- Pad test if quantity of leakage or objective outcome measure is desired (low sensitivity) (3)
- Do not routinely perform urodynamics before conservative treatment for UI (4)[B].
- Postvoid residual (PVR) volume if difficulty voiding or other lower urinary tract symptoms using ultrasound (US) to measure PVR: PVR persistently ≥100 mL indicates voiding dysfunction (1)[C].
- Uroflowmetry
- PSA only if diagnosis of prostate cancer will influence treatment or if levels can help decision making for patients at risk for BPH
- Renal function if renal impairment or hydronephrosis is suspected or if considering surgical treatment for lower urinary tract symptoms
- Voiding cystogram in select cases

Diagnostic Procedures/Other
- Urodynamics is useful for confirming bladder outlet obstruction as a possible cause of detrusor overactivity (4)[B].
- Prostate US and biopsy if indicated by physical exam or PSA level
- Urethrocystoscopy to exclude suspected bladder or urethral pathology or before invasive therapies if findings might influence treatment
- Imaging of upper and lower urinary tract is not routinely indicated as part of UI assessment.
- Consider US (preferred) or MRI of lower urinary tract if indicated.
  - US is rarely required to diagnose or rule out BPH in patients with UI because DRE can diagnose and guide treatment in most patients.
  - Consider US of prostate if it assists with choice of drug therapy for lower urinary tract symptoms.
  - Consider US of prostate to assess for intravesical prostatic protrusion (IPP) if considering surgical treatment.
  - Consider US of upper urinary tract in patients with large PVR, hematuria, or history of urolithiasis.

TREATMENT

Conservative, nonmedication interventions, such as behavioral modification, timed voiding, bladder training, and pelvic floor muscle training, should be considered first-line therapies, prior to initiating any pharmacologic therapy.

GENERAL MEASURES
- Bladder diaries are invaluable in helping patients understand patterns of incontinence (2)[A].
- Bladder training and timed voiding are effective (4)[A].
- Pelvic floor muscle training speeds recovery of continence following radical prostatectomy (4) [B], and preoperative PFMT seems to confer benefit in men undergoing radical prostatectomy.
Obesity increases the risk of UI, and weight loss may improve UI symptoms (3)[C]. Patients with underlying or associated disease states should have appropriate medical therapy for those diseases (5)[A]. Constipation is associated with UI, but treatment for constipation has not been shown to improve UI (4)—patients with constipation should receive standard care for their constipation (3)[C]. Reduction in caffeine intake does not improve UI but may improve urgency and frequency (2)[B]. Stopping smoking has not been shown to reduce UI, but patients should all be counseled to quit (4)[A]. Pads may be used for urine containment in UI as well as external sheaths (1)[B]—external sheaths may have similar rates of UTIs with indwelling catheters but result in better QoL (1)[B]. Penile clamps may also be used, and hinge type clamps are more effective than circular clamps (3)[B].

**MEDICATION**

**First Line**
- Urge incontinence: There is no consistent evidence that drug therapy is better than behavioral therapy in UUI (1)[B], and behavioral therapy results in higher patient satisfaction (1)[B].
- Antimuscarinic agents are first-line drug therapy in UUI (1)[B], and there is no evidence that any one agent is superior for UUI (1)[A].
- Oxybutynin (Ditropan XL) 5 to 15 mg PO every day
- Tolterodine (Detrol LA) 2 to 4 mg PO every day
- Darifenacin (Enablex) 7.5 to 15.0 mg PO every day
- Solifenacin (VESIcare) 5 to 10 mg PO every day
- Trospium chloride (Sanctura XR) 60 mg PO every day
- Transdermal oxybutynin (Gelnique) 10% apply daily (EAU Grade B)—no dry mouth
- Fesoterodine (Toviaz) 4 to 8 mg PO every day
- Mirabegron, a β3-agonist, has been shown in some trials and systematic reviews to be as efficacious as antimuscarinics (3)[B].
- Mirabegron (Myrbetriq): 25 to 50 mg PO daily. Caution: HTN
- Review efficacy and side effects 4 to 6 weeks after treatment initiation.
- Most patients will stop antimuscarinic therapy within 3 months due to adverse effects, nonefficacy, or cost (2).
- Caution in those with bladder outlet obstruction and PVR >250 to 300 mL: In men with urgency associated with BPH, consider α-blockers (i.e., tamsulosin, alfuzosin, silodosin) as monotherapy or in combination with antimuscarinic for residual overactive bladder (5).
- Stress incontinence
  - No generally accepted drug therapy
  - Mixed stress and urge incontinence; ER formulations are preferred due to reduced side effects.

**Second Line**
- Urge incontinence
- Tricyclic antidepressants
  - Imipramine 10 to 25 mg PO BID/TID
• Desmopressin (DDAVP) for occasional short-term relief of UI  
  – 25 to 50 μg PO or intranasal at bedtime  
• Intradetrusor botulinum toxin injections 100 U intravesical injections (not FDA-approved)  
• Duloxetine for temporary improvements of incontinence with dose titration (mixed stress/urge)

**Geriatric Considerations**

• Anticholinergics and tricyclics may result in significant cognitive impairment in elderly patients.  
• DDAVP should be avoided in patients with known/potential cardiac disease.

**ADDITIONAL THERAPIES**

• Pelvic floor rehabilitation (Kegel exercises) may significantly reduce both stress and urge incontinence in male patients and should be considered a part of initial management for stress UI.  
• Overflow incontinence is usually caused by poor bladder contractility with urinary retention.  
  – Indwelling or intermittent catheterization  
  – Evaluate for outlet obstruction.

**SURGERY/OTHER PROCEDURES**

• Urge incontinence  
  – Sacral nerve stimulation with behavioral therapy  
  – Augmentation cystoplasty and urinary diversion  
  – Botulinum toxin injection via cystoscopy  
• Stress incontinence (4)[B]  
  – Urethral bulking agents: modest success rates with low cure rates  
  – Male sling procedures: promising short-term and intermediate results but no long-term studies  
  – Artificial urinary sphincter implant has excellent long-term continence rates and is considered gold standard (6).

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Alternative modalities such as acupuncture, chiropractic, are not effective.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Must monitor residual volume after voiding in patients taking anticholinergic medications; monitor side effects.

**PROGNOSIS**

Continence can be improved in almost all patients.

**COMPLICATIONS**

• Dermatitis  
• Candidiasis  
• Skin breakdown
- Social isolation
- Avoidance of sex
- Weight gain

REFERENCES

ADDITIONAL READING

CODES

ICD10
- R32 Unspecified urinary incontinence
- N39.3 Stress incontinence (female) (male)
- N39.41 Urge incontinence

CLINICAL PEARLS

- Think “outside” the lower urinary tract: Comorbid medical illness and impairments are independently associated with UI; treat contributing comorbidities and rule out secondary causes.
- Always check PVR to rule out overflow incontinence.
- Have patient complete the International Prostate Symptom Score and do uroflow, PSA if indicated.
Pelvic floor rehabilitation handouts may be a good alternative for male patients, rather than physical therapy–mediated pelvic floor rehabilitation.
INFECTIOUS MONONUCLEOSIS, EPSTEIN-BARR VIRUS INFECTIONS

Dennis E. Hughes, DO, FAAFP, FACEP

BASICS

DESCRIPTION
- Epstein-Barr virus (EBV) is a member of the herpes virus family; human herpes virus 4 (1)
  - Two subtypes: ST1 predominates in Western Hemisphere, Southeast Asia; ST1 and ST2 equally prevalent in Africa
- Primary infection typically occurs in childhood; responsible for infectious mononucleosis (IM) (most common); also linked to numerous cancers.
- World Health Organization classified EBV as “tumor virus” (group I carcinogen) due to cancer association (1).

EPIDEMIOLOGY

Incidence
- Military recruits, college students, and others living in cloistered and crowded populations have highest infection rate. Overall rate in United States is 500/100,000 (2).
- Predominant age of primary infection is 15 to 24 years; 200 to 800/100,000 affected (2)
  - Primary clinical manifestation is IM.
  - Early childhood infections are usually asymptomatic. 50% of children infected by age 5 (3).
- Seroconversion occurs later in childhood in developed countries; there is suggestion of race/ethnicity disparity in the United States with higher seroprevalence in non-Hispanic black, Asian, and Hispanic populations (2).

Prevalence
Worldwide, infects >90% of people (antibody positive) by early adulthood (3)

ETIOLOGY AND PATHOPHYSIOLOGY
- After inoculation, the virus replicates in the nasopharyngeal epithelium with resulting cell lysis, virion spread, and viremia. The reticuloendothelial system is affected, resulting in a host response and the appearance of atypical lymphocytes in the peripheral blood. Viral genome can be detected in the oral cavity 1 week prior to symptoms.
- A polyclonal B-cell proliferative response follows. Relatively few (<0.1%) of the circulating lymphocytes are infected by EBV in the acute illness.
- A persistent (asymptomatic) state ensues with the EBV genome invisible to the immune system.
- During this period, coinfection increases risk for an EBV-associated condition (e.g., malignancy).
- Either through B-cell stimulation or diminished EBV-specific immune modulation, the previously latent EBV-infected B cells replicate, allowing clinical expression of the EBV genome. The proteins produced may either modify host response to or contribute directly to subsequent malignancy (1).
- Immunosuppression (organ transplant/acquired immune deficiency) can result in
transformation and lymphoproliferative disorders.

RISK FACTORS
● Age (highest incidence in adolescent, young adults)
● Socio-hygienic level (“crowded conditions”)
● Geographic location
● Close, intimate contact; especially “deep kissing” in adolescents and young adults (4)
● Immunosuppression
● Possibly some risk of transmission by fomites (e.g., shared toys, etc.) (5)

GENERAL PREVENTION
● Avoid close physical contact with symptomatic EBV/IM patients.
● Meticulous hand washing and hygiene
● General precautions with potential blood exposure (EBV can be transmitted via blood contamination as well as hematopoietic cell and solid organ transplant)
● EBV vaccines under investigation (lack of intimate knowledge of mechanism of immune response has impaired ability to develop an effective vaccine) (5)

COMMONLY ASSOCIATED CONDITIONS
● IM: Symptomatic primary EBV infection is common in otherwise healthy adolescents and young adults.
  – Clinical features vary in severity and duration: In children age <10 years, generally mild; in adolescents and adults, symptoms can be more severe and protracted (are dependent on intensity of T-cell response) (3).
  – Incubation period is 30 to 50 days (extremely long for a viral infection).
● X-linked lymphoproliferative syndrome (XLP—rare, inherited extreme vulnerability to EBV infection)
● Lymphoproliferative syndromes due to EBV infections in transplant recipients
● Lymphomas (B-cell lymphoblastic, T cell)
● Lymphocytic interstitial pneumonitis
● Hairy leukoplakia of the tongue, leiomyosarcoma, and central nervous system (CNS) lymphomas in patients with AIDS
● Burkitt lymphoma (most common childhood tumor in Africa and Papua New Guinea where malaria is also endemic and may be a cofactor)
● Nasopharyngeal carcinoma (particularly in SE China)
● Parotid carcinoma
● Hodgkin lymphoma (most common EBV-associated malignancy in United States, European Union)
● Postulated to be associated with multiple sclerosis (2 to 3 times incidence in EBV-positive individuals)
● Chronic active Epstein-Barr virus (CAEBV) due to loss of host control of viral replication

DIAGNOSIS
HISTORY
● May be either abrupt or insidious in onset
● Syndrome of fatigue, malaise, and sore throat
In adults, temperature may rise to 103°F (39.4°C) and gradually fall over a variable period of 7 to 10 days; in severe cases, temperature elevations of 104–105°F (40.0–40.6°C) may persist for 2 weeks.

- Children typically have low-grade fever or are afebrile.
- Rash
- Chest pain (myocarditis and pericarditis)

**PHYSICAL EXAM**

- Fever, lymphadenopathy, pharyngitis in >50%, with palatal petechiae and hepatosplenomegaly in ~10%
- Diffuse hyperemia and hyperplasia of oropharyngeal lymphoid tissue
- Gelatinous, grayish-white exudative tonsillitis persists for 7 to 10 days in 50%.
- Petechiae at border of hard and soft palates in 60%
- Bilateral upper eyelid edema (Hoagland sign)
- Axillary, epitrochlear, popliteal, inguinal, mediastinal, and mesenteric lymphadenopathy (95% of patients)
- Lymph node enlargement subsides over days/weeks.
- Tender lymphadenopathy (cervical nodes are most commonly enlarged)
- Splenomegaly in 50%
- Skin manifestations in 3–16%
  - Erythematous macular/maculopapular rash
  - Petechial and purpuric exanthems reported
  - Rash typically on trunk and upper arms; occasionally, the face and forearms are involved.

**DIFFERENTIAL DIAGNOSIS**

- Streptococcal pharyngitis and tonsillitis
- Diphtheria
- Blood dyscrasias
- Rubella
- Measles
- Viral hepatitis
- Cytomegalovirus
- Toxoplasmosis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Complete blood count with differential
- Lymphocytes and atypical lymphocytes
  - Increased numbers of lymphocytes (especially atypical lymphocytes; may be up to 70% of leukocytes) in peripheral blood
  - In 1st week after onset, white blood cell count is normal/moderately decreased. Due to EBV-related neutrophil fragility, automated processing can result in pseudoneutropenia.
    - By week 2, atypical lymphocytosis develops.
  - During early illness, atypical lymphocytes are B cells transformed by the EBV; later, atypical cells are activated CD8 T lymphocytes (4).
- Antibodies
  - Heterophile antibodies in 80–90% of adults
Heterophile antibody is an IgM response, which appears during the first 2 weeks of illness; disappears in 4 to 6 weeks.
- In general, agglutinin titer is higher in IM than other disorders; an unabsorbed heterophile titer $>1:128$ and $\geq 1:40$ is significant.

- Specific antibodies to EBV-associated antigens
  - Develop regularly in IM
  - Viral capsid-specific IgM and IgG are present early in illness.
  - Viral capsid-IgM disappears after several weeks; viral capsid-IgG persists for life.

- Liver tests: Transaminitis, hyperbilirubinemia are common; jaundice is rare.
- Atypical lymphocytes are not specific for EBV infections and may be present in other clinical conditions, including rubella, infectious hepatitis, allergic rhinitis, asthma, and atypical pneumonia.
- Routine abdominal ultrasound to monitor for splenic enlargement is not necessary.
- Consider ultrasound for those wishing to return to strenuous activity/contact sports at day 21 of illness to exclude splenomegaly.

**Follow-Up Tests & Special Considerations**
- Abnormal hepatic enzymes persist in 80% of patients for several weeks; hepatomegaly in 15–20%
- In transplant recipients, quantitative polymerase chain reaction (PCR) used to monitor EBV loads

**Diagnostic Procedures/Other**
- Chest x-ray
- Hilar adenopathy may be observed in IM with extensive lymphoid hyperplasia.

**Test Interpretation**
- Mononuclear infiltrations of lymph nodes, tonsils, spleen, lungs, liver, heart, kidneys, adrenal glands, skin, and CNS
- Bone marrow hyperplasia with small granulomas formation may be present; these findings are nonspecific and have no prognostic significance.

**TREATMENT**
- Treatment is mostly supportive.
- Nonsteroidal anti-inflammatory drugs or acetaminophen
- During acute stage, limit activity for 4 weeks to reduce potential complications (e.g., splenic rupture).
- Transplant recipients who develop EBV infection may require reduction in immunosuppression and administration of monoclonal anti-CD20 (rituximab).

**MEDICATION**
- In primary infections:
  - Antimicrobial agents (usually penicillin) only if throat culture is positive for group A $\beta$-hemolytic streptococci. Previously, ampicillin rash in presumed group B Streptococcus (GBS) was thought to be highly suggestive of IM. Incidence of rash is much lower than historically thought (4)[B].
- Warm saline gargles for oropharyngeal pain
- Corticosteroids
  - May provide some symptomatic relief but no improvement in resolution of illness
  - Consider in severe pharyngotonsillitis with oropharyngeal edema and airway encroachment. Dexamethasone 0.3 mg/kg/day may be used for 1 to 3 days.
  - Also for patients with marked toxicity/major complications (e.g., hemolytic anemia, thrombocytopenic purpura, neurologic sequelae, myocarditis, pericarditis) (6)[B]
- Antiviral medications (acyclovir) have been found to shorten recovery time and improve subjective symptoms in acute EBV infection in small studies.

**ISSUES FOR REFERRAL**
Most cases can be managed as an outpatient without the need for specialty referral. Consider referral for complications such as oropharyngeal edema with airway compromise.

**SURGERY/OTHER PROCEDURES**
- Splenectomy may be necessary with profound thrombocytopenia that is refractory to corticosteroids.
- Only current effective treatment for XLP is hematopoietic stem cell transplantation. There is some use of monoclonal antibody to delay progression pre-HST or treat relapse posttransplant.
- Splenic rupture

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**ALERT**
Rupture of the spleen may be fatal if not recognized; it requires blood transfusions, treatment for shock, and splenectomy. Occurrence is estimated at 0.1%.

**Patient Monitoring**
- Avoid contact sports, heavy lifting, and excess exertion until spleen and liver have returned to normal size (ultrasound can verify). Current consensus is that if after 3 weeks and normal exam, no fever, and no constitutional symptoms, patients may return to contact sport activities.
- Eliminate alcohol/exposure to other hepatotoxic drugs until liver function tests return to normal.
- Rates of complications are highest during the first 3 weeks of illness.
- Symptoms (malaise, fatigue, intermittent sore throat, lymphadenopathy) may persist for months.

**DIET**
No restrictions. Hydration is important.

**PROGNOSIS**
- Most recover in ~4 weeks.
- Fatigue may persist for months.

**COMPLICATIONS**
- Neurologic (rare)
- Aseptic meningitis, meningoencephalitis
- Bell palsy, Guillain-Barré syndrome
- Transverse myelitis
- Cerebellar ataxia
- Acute psychosis

- Hematologic (rare)
  - Thrombocytopenia, early in illness
  - Hemolytic anemia with neutropenia (early)
  - Hemophagocytic syndrome (splenomegaly, fever, cytopenia)
  - Agammaglobulinemia

- Pneumonitis
- Airway obstruction
- Splenic rupture
  - Rare, but most often occurs in first 21 days of illness

### REFERENCES

### ADDITIONAL READING

### CODES

**ICD10**
- B27.00 Gammaherpesviral mononucleosis without complication
- B27.09 Gammaherpesviral mononucleosis with other complications
- B27.01 Gammaherpesviral mononucleosis with polyneuropathy
CLINICAL PEARLS

- 98% of patients with acute IM present with some combination of fever, sore throat, cervical node enlargement, and tonsillar hypertrophy.
- False-negative monospot (heterophile antibody) is common in the first 10 to 14 days of illness. 90% will have heterophile antibodies by week 3 of illness.
- Lymphocytosis (not monocytosis) is common in IM.
- Treatment of IM is primarily supportive.
INFERTILITY
Sahil Mullick, MD ● Angela T. Cheriyan, MD

BASICS

DESCRIPTION
Definition: failure to conceive after 1 year of regular sexual intercourses without contraceptives in women <35 years of age. Or, failure to conceive after 6 months of regular intercourse without contraceptives in women >35 years of age. Primary: Couple has never been pregnant. Secondary: Couple has been pregnant. Fecundability: the probability of achieving pregnancy in one menstrual cycle

EPIDEMIOLOGY
Incidence
Incidence is the probability of achieving a pregnancy within 1 year. The incidence of infertility increases with age, with a decline in fertility in the early 30s, accelerating in the late 30s. ~85% of couples will conceive within 12 months of unprotected intercourse. ~95% of couples will conceive within 24 months of unprotected intercourse.

Prevalence
- About 25% of couples experience infertility at some point in their reproductive lives.
- ~9% couples between ages 15 and 34 years, 25% between ages 35 and 39 years, ~30% couples between the ages of 40 and 44 years meet the criteria for being infertile.
- May increase as more women delay childbearing; 20% of women in the United States have their first child >35 years.
- Centers for Disease Control and Prevention National Survey of Family Growth noted 12% of U.S. women >15 to 44 years old have impaired fecundity.

ETIOLOGY AND PATHOPHYSIOLOGY
- Most cases multifactorial: approximately 50% of cases due to female factors (of which 20% are due to ovulatory dysfunction and 30% due to tubal and pelvic pathology); ~26% due to male factors; 28% unknown etiology
- Acquired: Most common cause of infertility in the United States is pelvic inflammatory disease (PID) secondary to sexually transmitted infection, endometriosis, polycystic ovary syndrome (PCOS), premature ovarian failure, and increased maternal age.
- Diminished ovarian reserve (DOR): low fertility due to low quantity or functional quality of oocytes
- Congenital: anatomic and genetic abnormalities

Genetics
- Higher incidence of genetic abnormalities among infertile population, including Klinefelter syndrome (47,XXY), Turner syndrome (45X or mosaic), and fragile X syndrome
- Y chromosomal microdeletions are associated with isolated defects of spermatogenesis → found in 16% of men with azoo-/severe oligospermia.
- Cystic fibrosis transmembrane conductance regulator (CFTR) gene mutation causing congenital bilateral absence of vas deferens (CBAVD)
RISK FACTORS

- **Female**
  - Gynecologic history: irregular/abnormal menses, sexually transmitted infections (STIs), dysmenorrhea, fibroids, prior pregnancy
  - Medical history: advanced age, endocrinopathy, autoimmune disease, undiagnosed celiac disease, collagen vascular diseases, thrombophilia, obesity, and cancer
  - Surgical history: appendicitis, pelvic surgery, intrauterine surgery, tubal ligation
  - Social history: smoking, alcohol/substance abuse, eating disorders, exercise, advanced maternal age

- **Male**
  - Medical history: STI, prostatitis, medication use (i.e., β-blockers, calcium channel blocker, antiulcer medication), endocrinopathy, cancer
  - Surgical history: orchiopexy, hernia repair, vasectomy with/without reversal
  - Social: smoking, alcohol/substance abuse, anabolic steroids, environmental exposures, occupations leading to increased scrotal temperature (frequent use of saunas, hot tubs, or tight underwear), prescription drugs that impair male potency

GENERAL PREVENTION

Normal diet and exercise, avoid smoking and other substance abuse, prevention of STIs

COMMONLY ASSOCIATED CONDITIONS

- Sexual behavior increasing risk for STIs
- Pelvic pathology: endometriosis, ovarian cysts, endometrial polyps, and uterine fibroids
- Endocrine dysfunction (thyroid, glucose metabolism, menstrual cycle abnormalities, prolactin)
- Anovulation is commonly associated with hyperandrogenism and PCOS

DIAGNOSIS

HISTORY

- Complete reproductive history:
  - Age of female
  - Complete female reproductive history
    - Age at menarche, regularity of menstrual cycle, physical development, previous methods of contraception, history of abnormal Pap smears and treatment
    - History of abortion, dilation and curettages, bilateral tubal ligation, vasectomy, or other pelvic/abdominal surgery
  - Frequency of intercourse and any sexual dysfunction
  - Abdominal pain or other abdominal symptoms
  - History of STI
  - History of endocrine abnormalities
  - History of malignancy or chronic illness
  - Family history: close relatives with congenital abnormalities or mental retardation; infertility or early menopause in close relatives of female partner
  - Medications: drug abuse, allergies, occupation, and exposure to environmental hazards

PHYSICAL EXAM
- Body mass index (BMI), distribution of body fat, and waist circumference
- **Female**
  - Pubertal development with Tanner staging
  - Signs of PCOS: androgen excess, obesity, signs of insulin resistance
  - Breast exam: galactorrhea
  - Vaginal exam: Describe rugation, discharge, anatomic variation.
  - Uterine size/shape, mobility, tenderness
  - Adnexal tenderness, infection or mass
- **Male**
  - Abnormalities of the penis or urethral meatus
  - Testes: volume, symmetry, masses (varicocele, hydrocele), presence/absence of vas deferens

### DIAGNOSTIC TESTS & INTERPRETATION

#### Initial Tests (lab, imaging)
Evaluation is directed by history:
- **Assessment of ovulation**
  - Irregular or infrequent menses, not accompanied by consistent premenstrual or moliminal characteristics, which are inconsistent in flow and duration, are indicative of ovulatory dysfunction.
  - Elevated follicle-stimulating hormone (FSH) and luteinizing hormone (LH) but low estradiol indicate ovarian insufficiency. High LH alone suggests PCOS. Luteal-phase progesterone ≥3 ng/mL confirms ovulation has recently occurred but does not indicate when it occurred.
    - Use of basal body temperature charts to confirm ovulation is not a reliable method for ovulation prediction, but is low-cost and may be useful for some couples to guide timing of intercourse.
- **Assessment of ovarian reserve**
  - Women >35 years old need to have ovarian reserve assessed. On day 3 of menses, an FSH >15 to 20 IU/L is suggestive of impaired reserve.
  - Anti-müllerian hormone (AMH) and antral follicle counts (AFCs): The number of antral follicles measured by transvaginal ultrasound (US) is termed the “antral follicle count.” AMH is secreted by the granulosa cells of the antral follicles and decreases as a woman approaches menopause. AMH can be measured any time during the cycle and is not affected by hormones. AMH <0.7 μ/dL and total AFC <10 during the follicular phase indicates decreased reserve.
  - Clomiphene challenge test: After administration of clomiphene from day 5 to 9, measure FSH of ≥10 mIU/mL on day 10 to help confirm the diagnosis of DOR.
- **Semen analysis**
  - Warranted in all infertile couples. Semen analysis alone is not used to predict male fertility potential.
  - Semen collection: collected after 2 to 5 days of abstinence. Repeat test 2 to 3 times due to inherent variability within the same individual.
  - Parameters for normal male values: semen volume 1.5 mL or more, pH 7.2 or more, sperm concentration 15 million spermatozoa per mL or more, total sperm number 39 million spermatozoa per ejaculate or more, total motility: 40% or more motile or 32% or more with progressive motility, vitality 58% or more live spermatozoa, sperm morphology (percentage
of normal forms) 4% or more

- Additional labs
  - Prolactin, thyroid-stimulating hormone, 17-hydroxyprogesterone, androgen levels
  - HIV, herpes simplex virus 1 and 2, chlamydia, gonorrhea, rapid plasma reagin, hepatitis B and C, cytomegalovirus
  - Genetic testing based on family history
  - Postcoital testing of cervical mucus for the presence of motile sperm, which can be an effective predictor of conception

- Transvaginal ultrasound for anatomic abnormality
- Hysterosalpingogram (HSG) to evaluate patency of tubes and contour of the cavity; may be both diagnostic and therapeutic
- Sonohysterography (SHG) and laparoscopy with combined dye may provide a more detailed evaluation of the uterine cavity, if indicated.
- Endometrial biopsy to determine whether the defect of progesterone secretion during the luteal phase is from the corpus luteum, or from a defect in the endometrial response to stimulation causing inadequate implantation and pregnancy

Follow-Up Tests & Special Considerations
- Abnormal lab values warrant reevaluation/referral.
- Abnormal imaging may require surgical evaluation.

Diagnostic Procedures/Other
- Hysteroscopy: gold standard, used to directly visualize the endometrial cavity; may be indicated to evaluate filling defects on HSG or SHG
- Laparoscopy: used to directly visualize the peritoneal cavity and may be indicated to evaluate abnormal findings on HSG. Laparoscopy is the only way to definitively diagnose endometriosis.

Test Interpretation
Refer to section “Initial Tests.”

TREATMENT

GENERAL MEASURES
- Couples may wish to begin with simpler methods for determining ovulation and timing intercourse, depending on duration of infertility and resources available. Basal body temperature (BBT) tracking and/or detection of LH surge may be helpful for some. BBT: ~1 degree increase in BBT taken upon wakening indicates ovulation has occurred: Greatest fertility spans 7 days PRIOR to rise in BBT; LH testing kit: identifies midcycle LH surge, which occurs approximately 14 to 26 hours prior to ovulation. Greatest fertility on day of LH surge until 2 days after; predicts time of ovulation in advance so couples can time intercourse.
  - BBT is not as reliable as other methods for ovulation prediction.
- Be aware of insurance coverage for each patient. Be mindful of the couple’s emotional state: Depression, anger, anxiety, and marital discord are common. Many patients benefit from counseling and support measures.
- All female fertility patients should be given folate supplementation 1 mg/day by mouth.
- Additionally, dietary carotenoids in males may improve sperm quality.
In vitro fertilization (IVF) is the most effective infertility treatment available for women with unexplained infertility who have not conceived after 2 years of regular unprotected sexual intercourse:
- Eggs are removed from the female and fertilized outside the body. The embryo is monitored for 3 to 5 days and then implanted into the uterus on day 3 or day 5.
- Anatomic causes should be referred immediately for IVF, although surgical consult may be required.
- Fewer complications have been reported for individuals undergoing IVF for anatomic causes rather than ovulatory dysfunction (low APGAR scores, diabetes mellitus) (1)[A].
- Donor eggs may be obtained.
- Women <40 years of age or those who have not conceived after 2 years of unprotected intercourse or 12 cycles of artificial insemination should be offered 3 full cycles of IVF.
- Women ages 40–42 years with no evidence of previous IVF or low ovarian reserve should be offered 1 full cycle of IVF.

Intrauterine insemination without ovarian stimulation can be considered in special circumstances: physical disabilities limiting vaginal intercourse or psychosexual issues, people in same-sex relationships, etc. (please refer to “Male factor”)

Male factor
- Consider lifestyle changes.
- Intrauterine insemination (IUI): Sperm is placed via a catheter directly in the uterus. IUI effectively increases the sperm count.
- Intracytoplasmic sperm injection (ICSI) is performed in conjunction with IVF for males with severe abnormalities (i.e., <5 million sperm) or those who have failed to conceive with IUI. A single sperm is injected directly into the cytoplasm of the egg. Fertilization occurs ~70% of the time.
- Donor sperm may be obtained.

MEDICATION

First Line
- Treatment of infertility depends on the etiology.
- Women:
  - Anovulation: must determine if HYPOgonadotrophic or NORMOgonadotrophic
    o Hypogonadotropic patients: Standard treatment to induce ovulation consists of daily injections of both FSH and LH, which need to be carefully monitored to avoid overstimulation, resulting in ovarian hyperstimulation syndrome (OHSS).
    o Normogonadotropic patients: most commonly due to PCOS. Ovulation induction with letrozole (aromatase inhibitor) is possibly superior to clomiphene for patients with PCOS. Clomiphene citrate (Clomid). Regimen: 50 mg/day for 5 days beginning typically on CD 5 after spontaneous or progestin-induced withdrawal bleed. If no ovulation, increase dose to 100 mg/day in subsequent cycles; maximum 150 mg/day. Some will increase dose with ovulation but no pregnancy; most effective with ~10% body weight loss if obese
    o Unexplained infertility: The first-line therapy might be controlled ovarian hyperstimulation, as with clomiphene citrate and IUI. IVF may be recommended as second line.
  - Coital or cervical problems: IUI
  - Endometriosis: either IVF or surgery; medical therapy does not increase pregnancy rates.
– Lifestyle changes: Increasing frequency and timing of intercourse
• Male:
  – Lifestyle changes: Increasing frequency and timing of intercourse
  – Medications changes to improve sperm count, testicular function, sperm production and quality by discontinuing or changing certain selective serotonin reuptake inhibitor, calcium channel blocker and highly active antiretroviral therapy medications.
  – Surgery: reversal of sperm blockage (e.g., vasectomy, varicocele)
  – Sperm retrieval when ejaculation is problematic.

**Second Line**

If clomiphene and letrozole fail to induce ovulation:

• Metformin beneficial in anovulatory women with PCOS, especially those with glucose intolerance; initiate with 500 mg daily and increase to ~1,500 mg/day; monitor renal function; might take up to 3 months to be effective

• Consider also oral contraceptive pills (OCPs) for ≥2 cycles and then retry the clomiphene immediately after stopping the OCPs.

• Cabergoline or bromocriptine used if prolactin is elevated or if no withdrawal bleed after progesterone administration. Once pregnancy has occurred, the medication can be stopped.

• Human menopausal gonadotropins (hMGs) or recombinant FSH is indicated if there is resistance to clomiphene or if there is hypogonadotropism.

**ISSUES FOR REFERRAL**

Reproductive endocrinology and/or urology

**ADDITIONAL THERAPIES**

Consider using surrogate pregnancy if female cannot conceive.

**SURGERY/OTHER PROCEDURES**

Reproductive surgery may be necessary in those with anatomic causes of infertility.

- Polypectomy could be beneficial for large polyps obstructing the lumen of the uterus.
- Myomectomy may increase pregnancy success rates for intramural fibroids that obstruct or distort the uterine cavity. Salpingectomy is recommended and increases fertility in those with hydrosalpinx. In males with a varicocele, surgical treatment may improve sperm characteristics. Aspiration of sperm using transepidermal or microsurgical techniques may be useful.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Acupuncture may increase live birth rates with IVF.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Referred to infertility specialist if not successful after 3 to 6 cycles of oral ovulation induction.

**Patient Monitoring**

Cycle monitoring may decrease risks. US can show the number of developing follicles per cycle.

**DIET**

Obese, weight loss
PATIENT EDUCATION
- American Society for Reproductive Medicine (http://www.asrm.org)
- Resolve: patient advocacy group (http://www.resolve.org)

PROGNOSIS
Most couples will achieve a pregnancy

COMPLICATIONS
Anxiety, multiple pregnancy, OHSS a slight increased risk of congenital abnormalities

REFERENCES

SEE ALSO
- Amenorrhea; Endometriosis; Metabolic Syndrome; Polycystic Ovarian Syndrome (PCOS)
- Algorithm: Infertility

CODES
ICD10
- N97.9 Female infertility, unspecified
- N46.9 Male infertility, unspecified
- N97.1 Female infertility of tubal origin

CLINICAL PEARLS
- Women <35 years of age should be evaluated for infertility after failing to conceive after 1 year of unprotected intercourse, those ≥35 years should receive evaluation after 6 months, and those ≥40 years should receive assistance immediately.
- Medical therapy for endometriosis does not increase pregnancy rates, but surgical treatment does.
INFLUENZA
Kai-Soon “David” Yang, MD

BASICS

DESCRIPTION
- Acute, typically self-limited, febrile infection caused by orthomyxovirus influenza types A and B
- Marked by inflammation of nasal mucosa, pharynx, conjunctiva, and respiratory tract
- Outbreaks have varying degrees of severity and generally peak in winter.
- Influenza virus can undergo antigenic shift (abrupt change) leading to viral strains with little immunologic resistance in a population. This can result in pandemic outbreaks. Minor seasonal variations are called antigenic drift.
- Types of influenza include seasonal; pandemic; avian; swine
- System(s) affected: typical cases: head/eyes/ears/nose/throat, pulmonary; complicated cases: cardiac and CNS involvement
- Synonym(s): flu; grippe; acute catarrhal fever

EPIDEMIOLOGY
- Predominant age: children (3 months to 16 years) and young adults
  - Morbidity: seasonal morbidity and rates of hospitalization highest in very young (preschool), elderly (>75 years of age), and individuals with comorbid illness (lung disease, malignancy)
- Predominant sex: male = female

Incidence
- Seasonal influenza in preuniversal vaccination: 95 million cases per year, typically fall/winter
- Attack rates in healthy children: 10–40% each year, prior to routine influenza vaccination
- Weekly reports: https://www.cdc.gov/flu/weekly

Prevalence
2017–2018 was a high severity influenza season. Disease appeared in November and had high activity through March. The 19 weeks of persistent influenza activity was longer than usual.

ETIOLOGY AND PATHOPHYSIOLOGY
Orthomyxovirus (influenza types A [majority] and B); influenza A virus subtypes HxNx based on hemagglutinin and neuraminidase
- Incubation is 1 to 4 days; infected persons are most contagious during peak symptoms.
- Spread by aerosolized droplets or contact with respiratory secretions
- Hemagglutinin binds to columnar respiratory epithelium where replication occurs, and neuraminidase protein facilitates spread along respiratory epithelium.

RISK FACTORS
- For contracting disease
  - Crowded environments such as nursing homes, barracks, schools, and correctional facilities
- For complications
– Neonates, infants, elderly
– Pregnancy, especially in 3rd trimester
– Chronic pulmonary diseases
– Cardiovascular diseases, including valvular pathology and congestive heart failure (CHF)
– Metabolic disease, morbid obesity
– Hemoglobinopathies
– Malignancy; immunosuppression
– Neuromuscular diseases that limit respiratory function and ability to handle secretions

**GENERAL PREVENTION**

* Vaccination: All persons >6 months should be vaccinated annually unless contraindication present.
  – Inactivated influenza vaccine (IIV) is available with either 3 (IIV3) or 4 (IIV4) strains of influenza. IIV also is available as high-dose, intradermal, cell culture–based (ccIV3), MF59-adjuvanted (aIIV3), and recombinant hemagglutinin vaccine (RIV3).
  – Live attenuated influenza vaccine (LAIV) is an intranasal quadrivalent vaccine.
* IIV recommended annually for the following:
  – All persons aged ≥6 months
  – Vaccine should be administered annually as soon as the vaccine is available.
  – Protection occurs 1 to 2 weeks after immunization.
  – Typically, mild side effects include low-grade fever and local reaction at vaccination site.
  – Inactivated IM dose: ≥3 years of age: 0.5 mL; children 6 to 35 months of age: 0.25 mL
  – Intradermal formulation for 18 to 64 year olds uses a short 30-gauge needle in a single-use prefilled syringe with 0.1 mL vaccine; somewhat higher local reactions when given intradermal
  – Single annual dose except for children <9 years of age, who should receive 2 doses (4 weeks apart) the 1st year they receive influenza vaccine
  – Vaccine contraindication: Severe allergy such as anaphylaxis to IIV components, allergies from eggs are not considered a contraindication; observe all patients for 15 minutes after vaccination; no skin testing with influenza vaccine is needed in egg-allergic patients. RIV is safe in patients with an egg allergy.
  – Precaution: Guillain-Barré syndrome within 6 weeks after a previous dose of influenza vaccine
* LAIV is available for 2019–2020 influenza season.
* IIV-HD: high-dose quadrivalent IIV
  – Contains 4 times the antigen concentration of IIV
  – Licensed for persons ≥65 years of age
  – Results in higher antibody levels but somewhat higher rates of local reactions
  – Advisory Committee on Immunization Practices does not express a preference for/against IIV-HD.
* Antiviral prophylaxis depends on current resistance patterns each year; see [ https://www.cdc.gov/flu/](https://www.cdc.gov/flu/) for patterns or check with local health department.
  – In high-risk groups that have not been vaccinated or need additional control measures during epidemics; not a substitute for vaccination unless vaccine is contraindicated (1)[A]
  – During influenza season, for those with contraindications to vaccine who have been exposed to the virus (1)[A]
  – For staff and residents in nursing home outbreaks
For immune-deficient persons who are expected not to respond to vaccination after viral exposure

**Pediatric Considerations**
- Vaccinate children 6 months and older annually.
- Recommend all household members with children <6 months be vaccinated (2)[A].
- For children who need 2 doses, administer first dose as soon as available for second dose to be given before the end of October (2)[A].
- For prophylaxis, oseltamivir dosage varies by weight and is recommended by the CDC for prophylaxis for children ≥3 months; zanamivir is approved for prophylaxis for children ≥5 years of age at a dosage of 2 inhalations per day. Prophylaxis treatment duration is 7 days. For prophylaxis, the dosage of amantadine and of rimantadine is 5 mg/kg/day up to 150 mg in 2 divided doses. Currently, amantadine and rimantadine are not recommended due to resistance.

**Pregnancy Considerations**
- The CDC recommends vaccinating all women who will be pregnant during influenza season.
- If unvaccinated at the time of flu season, pregnant women should receive IIV or RIV.
- Oseltamivir, zanamivir, peramivir, rimantadine, and amantadine are pregnancy Category C.

**COMMONLY ASSOCIATED CONDITIONS**
Bacterial pneumonia

**DIAGNOSIS**
Look for:
- Systemic symptoms
- Cough
- Not being able to cope with daily activities
- Being confined to bed

**HISTORY**
Sudden onset of:
- Fever (37.7–40.0°C), especially within 3 days of illness onset
- Anorexia
- Chills, sweats, malaise, myalgia, arthralgia
- Headache
- Sore throat/pharyngitis
- Nonproductive cough
- Rhinorrhea, nasal congestion

**PHYSICAL EXAM**
- Physical exam is not specific for influenza.
- Physical examination should exclude complications such as otitis media, pneumonia, sinusitis, and tracheobronchitis.

**DIFFERENTIAL DIAGNOSIS**
- Respiratory viral infections including respiratory syncytial virus, parainfluenza, adenovirus, enterovirus (“influenzalike illness”)
Infectious mononucleosis
Coxsackievirus infections
Viral or streptococcal tonsillitis
Atypical mycoplasmal pneumonia
Chlamydia pneumoniae
Q fever
Less likely possibilities include severe acute respiratory syndrome, primary HIV infection, acute myeloid leukemia, tuberculosis, anthrax, and malaria.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

During influenza season, diagnosis is based solely on clinical findings. If additional testing is needed:

- Viral culture is gold standard for diagnosis but is of limited practical value due to the time it takes for results to become available.
- Reverse transcription polymerase chain reaction (RT-PCR) from nasopharyngeal swab or aspirate is the test of choice for diagnostic confirmation.
- CBC: typically shows normal WBC count or mild leukopenia. Leukocytosis may indicate bacterial complications.
- Direct fluorescent antibody or indirect fluorescent antibody staining for influenza antigen; results available in hours (dependent on lab expertise)
- Commercial rapid enzyme-linked immunosorbent assay antigen tests are available. Some rapid tests diagnose influenza A, others diagnose A and B. Sensitivity and specificity vary by manufacturer, strain of influenza, and age of patient. False-negative results are common, particularly during peak influenza activity.
- Viral isolation is not useful except during periods of low influenza activity (if making the correct diagnosis is critical).

**Imaging**

- Chest x-ray if pneumonia is suspected

**TREATMENT**

- Symptomatic treatment (saline nasal spray, analgesic gargle, antipyretics, analgesics)
- Cool-mist or ultrasonic humidifier to increase moisture of inspired air
- 5 days is the average period of viral shedding in immunocompetent hosts.
- Hospitalized patients may require oxygen or ventilatory support.
- Tobacco cessation

**MEDICATION**

- Antiviral treatment depends on yearly resistance patterns; check [https://www.cdc.gov/flu/](https://www.cdc.gov/flu/) or with local health department. Antivirals are most effective if administered within first 48 hours in laboratory-confirmed (or highly suspected based on clinical findings) influenza cases.
- Antivirals within 48 hours of symptom onset are recommended for patients at risk of complications (i.e., diabetes, CHD, COPD, asthma, etc.) (1)[A].
Antivirals are recommended if hospitalized (3)[A].
Antivirals include baloxavir, oseltamivir, zanamivir, and peramivir. Amantadine and rimantadine currently are not recommended due to resistance.
Consider antivirals for patients whose onset of symptoms is within the past 48 hours and who wish to shorten the duration of illness and further reduce their relatively low risk of complications (1)[A].
Symptomatic treatment is preferred for those patients without risk factors and without signs of lower respiratory tract infection (3)[A].
Effect is 24-hour reduction of symptoms and a reduction in complication rates.
  - Baloxavir dose: oral, 1-time dose
    o 40 to <80 kg, 40 mg
    o >80 kg, 80 mg
    o For children >12 years, use adult dosing.
  - Zanamivir dose: 2 inhalations BID for 5 days (age ≥7 years)
  - Oseltamivir dose: 75 mg PO BID for 5 days (age ≥13 years)
  - If severe renal impairment, 75 mg/day PO
  - Oseltamivir for children ≥1 year of age
    o <15 kg, 30 mg BID
    o >15 to 23 kg, 45 mg BID
    o >23 to 40 kg, 60 mg BID
    o >40 kg, 75 mg BID
  - Oseltamivir for children <1 year of age: 3 mg/kg/dose BID
  - Peramivir dose: 600 mg IV infusion over 15 to 30 minutes for adults ≥18 years of age
Antipyretics
  - Acetaminophen: in children
Precautions
  - Zanamivir may cause bronchospasm if the patient has COPD or asthma; the patient should have a bronchodilator available.
  - Amantadine has anticholinergic properties and should be used with caution in those with psychiatric, addiction, or neurologic disorders because it may increase risk for suicide attempts or increase neurologic symptoms.
  - Rimantadine may increase the risk of seizures in those with an underlying seizure disorder.
  - Oseltamivir may cause nausea and vomiting; may be less severe if taken with food
  - Peramivir may cause serious skin reactions.
Decrease dose of certain antivirals if creatinine clearance <60 mL/min.
  - Ibuprofen or other NSAIDs for symptomatic relief
  - Aspirin: should not be used in children <16 years due to risk of Reye syndrome
  - Outpatient treatment is sufficient except for cases with severe complications or in high-risk groups.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
  - Mild cases: Usually, no follow-up is required.
  - Moderate or severe cases: Follow up until symptoms and any secondary sequelae resolve.
DIET
Increase fluid intake.

PATIENT EDUCATION
CDC: https://www.cdc.gov/flu/

PROGNOSIS
Good

COMPLICATIONS
- Otitis media; acute sinusitis
- Croup; bronchitis
- Pneumonia (primary viral or secondary bacterial)
- Apnea in neonates
- Reye syndrome
- Rhabdomyolysis/myositis
- Postinfluenza asthenia
- COPD or CHF exacerbation
- Encephalopathy, death

Geriatric Considerations
Complications requiring hospitalization are more likely in elderly patients.

REFERENCES

ADDITIONAL READING

CODES
ICD10
- J11.1 Influenza due to unidentified influenza virus with other respiratory manifestations
- J10.1 Flu due to oth ident influenza virus w oth resp manifest
- J11.00 Flu due to unidentified flu virus w unsp type of pneumonia
CLINICAL PEARLS

- Influenza is an acute, (typically) self-limited, febrile infection caused by influenza virus types A and B.
- All persons >6 months should be vaccinated against influenza on an annual basis (there are rare exceptions).
- Complications from influenza are most common in the very young, very old, and individuals with comorbid disease.
- Hand hygiene either with soap and water (slightly superior) or with alcohol-based hand rubs and covering coughs are simple ways to reduce the spread of influenza.
**INGROWN TOENAIL**
Sally-Ann L. Pantin, MD, FAAFP • Thomas A. Waller, MD

**BASICS**

**DESCRIPTION**
- In an ingrown toenail, the distal margin of the nail plate grows into the lateral nail fold, causing irritation, inflammation, and sometimes bacterial or fungal infection:
  - Stage 1 (inflammation): erythema, edema, tenderness to palpation of lateral nail fold
  - Stage 2 (abscess): increased pain, erythema, and edema as well as drainage (purulent or serous)
  - Stage 3 (granulation): Chronic inflammation leads to further erythema, edema, and pain, often with granulation tissue growing over the nail plate and significant nail fold hypertrophy.
- Can recur
- Synonym(s): onychocryptosis, unguis incarnatus

**EPIDEMIOLOGY**
- Great toenail is most often affected.
- Lateral edge of nail is more commonly affected than the medial edge.
- Most common in males aged 14 to 25 years
- Infrequent, but more often in elderly females than in elderly males
- More common in those with lower incomes

**Prevalence**
- 24.5/1,000 overall
- 50/1,000 ≥65 years

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Nail plate penetrates the nail fold, causing a foreign body reaction (inflammation).
- Bacteria or fungi may enter through the opening in the nail fold, causing infection and abscess formation.
- The inflamed and infected area leads to granulation tissue and hypertrophy of the nail fold.

**RISK FACTORS**
- Genetic factors
  - Increased nail fold width
  - Decreased nail thickness
  - Medial rotation of the toe
- Many others proposed; none proven, including the following:
  - Distorted, thickened nail (onychogryphosis)
  - Fungal infection (onychomycosis)
  - Hyperhidrosis
  - Improper trimming of the lateral nail plate
  - Poorly fitting shoes
  - Trauma to nail or nail fold
Conditions that predispose to pedal edema (i.e., thyroid dysfunction, diabetes, obesity, heart failure, renal disease)

GENERAL PREVENTION
- Properly fitting shoes
- Proper nail trimming (see “Patient Education”)

DIAGNOSIS

HISTORY
- Patients most often present with pain, redness, and swelling in the toe along one or both sides of the nail.
- Drainage can occur as inflammation and/or infection develop.

PHYSICAL EXAM
- Nail fold tenderness
- Erythema and edema
- Drainage (serous or purulent)
- Granulation tissue
- Lateral nail fold hypertrophy

DIFFERENTIAL DIAGNOSIS
- Cellulitis
- Felon (pulp abscess on plantar aspect of toe)
- Onychogryphosis (gross thickening and hardening of the nail)
- Onycholysis (separation of nail from nail bed)
- Onychomycosis (fungal infection of the nail)
- Osteomyelitis
- Paronychia (infection or inflammation around the nail fold)
- Subungual exostosis (bony projection from distal phalanx)
- Subungual osteochondroma (benign bone tumor)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
None usually needed
- Consider MRI, x-ray, or bone scan if osteomyelitis is suspected.
- Consider x-ray if subungual exostosis or osteochondroma is suspected.

TREATMENT

GENERAL MEASURES
- Majority of cases respond to conservative therapy.
- Warm, soapy water or Epsom salt soaks for 10 to 20 minutes 3 times per day until symptoms resolve (1)
- Bluntly insert a cotton wisp or dental floss underneath the ingrown portion of the nail. The patient can continue to replace the insert until the nail grows beyond the fold.
Use tape to pull the lateral nail fold away from the nail plate until the nail grows beyond the fold.

Stage 2 ingrown nails often respond to conservative treatment, as above, especially cotton wool, or a trial of cryotherapy.

**MEDICATION**
- NSAIDs are usually adequate for analgesia.
- Topical antibiotic can be applied after soaking (1).
- Neither oral nor topical antibiotics are useful as an adjunct to surgical treatment.

**SURGERY/OTHER PROCEDURES**
- Surgical interventions are more effective than nonsurgical interventions in preventing recurrence (2,3)[A].
- Nail avulsion techniques are more effective than nail fold debulking techniques (not described in this topic) (3)[A].
  - Partial avulsion of the nail with phenol nail matrix ablation
    - Obtain surgical consent after explaining the risks, benefits, and alternatives.
    - Achieve local anesthesia with a digital wing or ring block.
    - May consider placing a tourniquet around the base of the toe to assist with hemostasis (caution in patients with diabetes or peripheral vascular disease).
    - Elevate the ingrown part of the nail from the nail bed with a periosteal (Freer) elevator or hemostat.
    - Incise the nail longitudinally with scissors or a nail splitter a few millimeters from the ingrown border, starting at the distal edge and proceeding to the matrix.
    - Grasp, down to the cuticle, the avulsed fragment with a hemostat and pull this portion gently out with a hemostat, utilizing longitudinal traction, as well as rotation to the lateral nail fold if needed.
    - Remove the tourniquet once hemostasis is attained.
    - Dip a urethral swab in 80–88% phenol solution (phenol use is contraindicated in pregnancy).
    - Apply the phenol 3 times for 30 seconds to the nail matrix under the proximal nail fold. Wash the area with 70% isopropyl (rubbing) alcohol to neutralize phenol.
- Nonsurgical interventions, such as a flexible gutter splint, are another option for treatment of stage 2 or 3 ingrown nails (4,5)[B].
  - J Flexible gutter splint
    - Cut a 1- to 2-cm long piece of sterilized plastic tube, such as IV tubing, 2 to 3 mm in diameter (alternatively, you may use a cap from a 29-gauge needle).
    - Make a slit in the tubing lengthwise and cut the end off at an angle.
    - Apply local anesthesia with a digital wing or ring block.
    - Release the ingrown edge of the nail from the nail fold with a hemostat.
    - Slide the tube, angled end first, along the ingrown edge of the nail.
    - Consider fixing the tube in place with self-curing formable acrylic resin (used for dentures and sculptured nails), tape, or a single suture through the nail plate.
    - Leave the tube in place until nail has grown beyond the nail fold.
- Bilateral partial matricectomy should be considered in patients with severe ingrown toenail or recurrence.
- Permanent destruction of the germinal matrix can be used to prevent recurrence. The use of
phenol for nail bed ablation is probably more effective than nail avulsion alone in preventing recurrence (2,3)[A].

– Other options for nail bed ablation:
  o Sodium hydroxide (NaOH)
  o Cryotherapy
  o Electrocautery with a special flattened tip coated with Teflon on one side to protect the proximal nail fold
  o Carbon dioxide laser
  o Surgical excision of the nail matrix

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

● Dress with antibiotic ointment or sterile petroleum jelly; cover with sterile gauze and tube gauze.

● Postop instructions should include the following:
  – Rest and elevate the foot for 12 to 24 hours.
  – Take NSAIDs for discomfort.
  – Change dressing and wash with soap and water at least daily for 1 to 2 weeks following procedure.
  – Expect a sterile exudate for 2 to 6 weeks.
  – Avulsed nails may take 6 to 12 months to grow completely out (if no matrix ablation).
  – Call for increasing pain, redness, or swelling.
  – Average time to return to normal activities is 2 weeks.

● Patients treated conservatively should be followed up in the office every 7 to 10 days until marked improvement is noted.

PATIENT EDUCATION

● Trim nails straight across perpendicular to long axis of the nail (do not round corners) and not too short.

● Wear properly fitting, comfortable shoes.

COMPLICATIONS

● Cellulitis after surgical procedure (uncommon)
● Damage to fascia or periosteum from overly aggressive matrix ablation
● Damage to nail bed
● Distal toe ischemia due to prolonged use of a tourniquet during surgery (rare)
● Nail plate deformity (due to nail matrix damage)
● Osteomyelitis (rare)
● Permanent narrowing of nail (if partial matrix ablation is performed)
● Persistent postoperative wound drainage particularly with excessive phenolization of adjacent tissues
● Recurrence (40–80% with avulsion alone, 0.6–14% with matrix ablation, 6–13% with gutter splint)

CODES

ICD10
L60.0 Ingrowing nail

CLINICAL PEARLS

- The best treatment for a stage 1 ingrown toenail is to insert a wisp of cotton or dental floss between the nail plate and lateral nail fold.
- The best treatment for a stage 3 ingrown toenail is partial nail avulsion with phenol matrix ablation.
- Patients can prevent ingrown toenails by trimming nails properly and wearing properly fitting shoes.
- Oral and topical antibiotics are not useful in the treatment of ingrown nails in conjunction with
surgical treatment.
INJURY AND VIOLENCE
Jonathan R. Ballard, MD, MPH, MPhil  Tisha K. Johnson, MD, MPH

BASICS

DESCRIPTION
- Injury, intentional or not, is often predictable and preventable.
- Unintentional injuries are no longer considered “accidents” given that most injuries are preventable.
- As of 2017, unintentional injury is the 3rd leading cause of death, and suicide is the 10th leading cause of death in the United States.
- Injury is the leading cause of death of people aged 1 to 44 years and a leading cause of disability for people of all ages, regardless of sex, race/ethnicity, or socioeconomic status.
- Violence-related deaths accounted for over 66,500 deaths in the United States in 2017 (over 47,000 suicides, over 19,500 homicides).

Source: Centers for Disease Control and Prevention (CDC) Web-based Injury Statistics Query and Reporting System (WISQARS)

- Children mostly die of unintentional injuries: motor vehicle accidents (MVAs), drowning, and suffocation.
- MVAs are the most common type of unintentional injury deaths in adolescents.

ALERT

Poisoning, which includes drug overdose, has been the leading cause of injury deaths in the United States overall since 2011. It is particularly deadly for persons aged 15 to 64 years (leading cause of injury deaths among 25 to 64 year olds; second leading cause of unintentional injury deaths for 15 to 24 year olds).

- Approximately 5.8 million people worldwide die yearly from injuries, of which all forms of violence combine to cause nearly 1/3 of these deaths (World Health Organization [WHO]).
- Unintentional motor vehicle traffic deaths rank second in the United States for overall injury deaths, first in those aged 5 to 24 years and second in those aged 1 to 4 years and 25 to >65 years.
- Among leading causes of injury deaths in the United States, unintentional falls rank third overall. Firearms are related to the fourth and fifth leading causes of injury deaths in the
United States, suicide and homicide, respectively.

- Homicide is the third leading cause of death in 2016 for persons 15 to 34 years of age in the United States.

**ALERT**
Consider homicide as cause of unexplained death in young children.

**ETIOLOGY AND PATHOPHYSIOLOGY**
Multifactorial

**RISK FACTORS**

- MVAs:
  - MVAs accounted for 40,528 deaths in 2016 with an age-adjusted rate of 12.2 deaths per 100,000 persons.
  - >2.5 million adult drivers and passengers were treated in emergency departments (EDs) in 2015.
  - Young adults (20 to 24 years old) have the highest crash-related injury rates.
  - In the United States, 1 in 3 deaths involved drunk driving and almost 1 in 3 deaths involved implicated speeding.
  - Motorcyclists are more likely to die in a motor vehicle crash than car occupants. The risk of death is reduced by 37% with helmets.
  - Risk factors for involvement in an MVA include high speed, teenage drivers, consumption of alcohol or drugs affecting the central nervous system, fatigue, and distracted driving (handheld mobile phones and inadequate visibility).
  - Increased risk of death by MVA: male driver, inexperience, nighttime driving, speeding, tailgating, driving with other teenagers, cell phone use, unrestrained occupants, use of older cars, nonuse of crash helmets, alcohol, and drug use. In elderly, poor vision, medical conditions, and comorbidities increase risk of death by an MVA (CDC, National Center for Injury Prevention and Control [NCIPC], and WHO).

- Pedestrians:
  - 5,376 pedestrians were killed by motor vehicles and nearly 129,000 were treated in EDs for nonfatal injuries (2015; CDC, NCIPC).

- Bicycles (WHO):
  - Risk of death from crash with motor vehicle increases if speed >30 km/hr (~18 mph) and if there is impact with front of vehicle.
  - Risk factors for cyclist injury include alcohol consumption, shared use motorways, poor visibility, lack of understanding of road safety, and design/type of impacting vehicle.

- Sports- and recreation-related injury (CDC):
  - >2.6 million children (0 to 19 years) treated in EDs each year; males, deconditioned adults, and athletes playing collision or contact sports are at also increased risk.

- Drowning: a leading cause of unintentional injury death among all children, particularly 1 to 4 years of age; children at increased risk include African Americans and those unattended in bathtubs, swimming pools, and recreational water activities (CDC, NCIPC).

- Suffocation: increased risk for children <1 year of age, unsafe sleeping environments (CDC)

- Falls (CDC, NCIPC):
  - The leading cause of nonfatal injuries and most common cause of traumatic brain injuries (TBIs)
– Poor vision, psychotropic medications and diuretics, arthritis, impaired mobility, inappropriate footwear and walking aids, cognitive impairment, gait imbalance, environmental risk factors (1)

- **Violence**: risk factors: adverse childhood exposures (ACEs); lack of access to social capital, community organization, and economic resources; familial instability; community and family violence; access to firearms; mental health; personal or household member alcohol and drug use; exposure to suicidal behavior; history of aggressive behavior; cognitive deficits; poor supervision; poor peer-to-peer interaction; academic failure; poverty; lower socioeconomic class (CDC)
- Homicide: third leading cause of death for persons aged 15 to 34 years in the United States (CDC) Most common victims are young males. Firearms are used in more than half of U.S. homicides.
- Suicide: Females are more likely to have suicidal thoughts, but males are 4 times more likely to complete suicide. Most common methods are firearms for males and poisoning for females. (CDC, NCIPC).
- Adolescent violence (CDC):
  – In 2015, nearly 8% of students participated in ≥1 fights at school in the last year.
  – >5% of high schoolers reported not going to school on ≥1 day(s) in the last 30 days because they felt unsafe at school or on their way to school.
  – 4% of students have carried a weapon to school; 6% of students have been threatened or injured by a weapon at school.
- Bullying (CDC):
  – 20% of 9th- to 12th-grade students bullied on school property in the last year
  – 15% of students report cyberbullying.
  – Bullying is associated with social, emotional, and academic difficulties.
- Interpersonal and intimate partner violence (IPV):
  – WHO reports about 38% of female homicides were committed by partners, similar to CDC reports of 40% of female homicide victims.
  – In their lifetime, approximately 8.5 million women and >4 million men report physical violence, rape, or stalking from an intimate partner, many before the age of 18 years (CDC).
  – Dating violence: Of high school students who dated in the previous 12 months, 12% of girls and 7% of boys experienced physical violence, and 16% of girls and 5% of boys experienced sexual violence (CDC).
  – Increased risk for female, history of IPV or sexual assault or child abuse, alcohol or drugs, marital difficulties, unemployment, emotional or mental health problems, income or educational disparity, poverty

**ALERT**

**Poisonings** (CDC):
- The United States’ epidemic of drug overdoses (poisonings) includes more than half a million deaths from 2000 to 2015, mainly from opioids (>6 out of 10, ~91 deaths per day).
- Since 1999, prescription opioids sold in the United States have almost quadrupled, and deaths from prescription opioids have more than quadrupled.
- >33,000 people died from opioid overdoses in 2015; a 15% increase in opioid-death rates from 2014 to 2015 is likely due to illicit opioids, including synthetic opioids (72%) such as fentanyl and fentanyl analogs and heroin (20%).
Overlapping prescriptions of pain relievers or other sedating drugs, high doses, history of mental illness or substance abuse, uninsured or Medicaid, low income increase risk for overdose deaths.

Consider opioid-induced poisonings in unexplained altered mental status.

**DIAGNOSIS**

**HISTORY**

- Mechanism, timing, and location of injury:
  - Blunt versus penetrating; intentional versus unintentional; others injured versus isolated injury; circumstances (weather, substance use, restrained vs. unrestrained)
  - Does history correlate with level of injury (i.e., level of suspicion for abuse [elderly, child, or partner])?
  - Is further evaluation required (blood and/or urine testing, response to opioid receptor antagonists, imaging)?
- IPV: neurologic deficits, seizures, chronic pain, gastrointestinal, sexually transmitted infection, pregnancy, psychiatric presentations
  - Screen women of childbearing age for IPV and intervene if screening results are positive.

**TREATMENT**

- Prevention: The primary focus for reducing injury and violence is individually tailored prevention based on risk factors combined with population-level prevention (2). The “three Es”: education, engineering strategies, and enforcement of laws (2). The “Haddon Matrix” describes injury events in terms of three influencing factors (host, agent/vector, environment) and three phases (pre-event, event, postevent) (1,2).
- Primary (i.e., prevent crash), secondary (i.e., prevent injury from crash), and tertiary (i.e., prevent poor outcomes from injury) prevention (1,2)[C]
- Acute setting: Follow basic life support (BLS), advanced trauma life support (ATLS), advanced cardiovascular life support (ACLS), and pediatric advanced life support (PALS) guidelines (2,3)[A].
- Motor vehicle injuries (CDC):
  - Infants, toddlers, and children: age-appropriate child safety seats and passenger restraints with distribution programs, education programs for parents and caregivers, safety seat checkpoints, penalties for drivers transporting children under the influence of drugs and/or alcohol, legislation regarding restraint of motor vehicle occupants (1)[A]
  - Adolescents and adults: seat belts, air bags, graduated driver licensing programs, blood alcohol concentration laws, minimum drinking age laws, sobriety checkpoints, ignition interlocks, programs for alcohol servers, zero-alcohol tolerance laws for young drivers, school-based education programs on drinking and driving. Emergency medical services (EMS) response times, engineering cars for rapid extraction, organized trauma systems; collapsible automobile steering columns have been shown to decrease injury mortality and morbidity; texting and driving penalties (1)[B]
  - Older adults: alternative transportation programs, screening for high-risk drivers, gradual curtailment of driving privileges, more frequent license renewal process (1)[B]
Bicycle helmets can reduce risk of head injury by 63–88%. Canadian helmet legislation decreased mortality by 52% (1)[B].

Pedestrian injury: pedestrian safety education, reflective clothing, use of crosswalks, limit mobile phone use while crossing roads (1)[B], street lighting for pedestrians (1)[A], fluorescent clothing for pedestrians and cyclists (1)[A]

Cyclists injury: flashing lights and reflectors at night (2)[B], helmet use and laws (1)[A], cyclists separation from motor vehicles (1)[B]

- Sports-related injuries:
  - Proper equipment: Helmets can prevent bicyclist head injuries and mortality (1)[A].
  - Plan of action for dealing with concussion and head injury in young athletes, with guidelines regarding if or when it is safe to return to play (CDC)

Drowning:
- Improved supervision of young children, especially for those with epilepsy; swimming lessons; trained lifeguard supervision; fencing; locked gates and pool alarms; no use of alcohol in recreation aquatic activities; personal flotation devices and boating safety awareness; parental and caregiver certification in cardiopulmonary resuscitation (1)[B]

Falls:
- Home safety assessments, installation of handrails and grab bars, removal of tripping hazards, nonslip mats, exercise programs such as tai chi to improve strength and balance, night lights, cataract surgery, gradual withdrawal of psychotropic medication (1)[B]
- In April 2018, U.S. Preventive Services Task Force (USPSTF) recommends exercise interventions to prevent falls in community-dwelling adults aged 65 years or older who are at increased risk for falls (4)[A].

Violence (homicide, suicide, assaults) (CDC):
- Primary prevention: Most effective strategies focus on younger age groups to change individual attitudes and behaviors (1)[C].
- Secondary prevention: Detect and identify violence in early stages (1)[B]. The USPSTF recommends that clinicians screen women of childbearing age for IPV, such as domestic violence, and provide or refer women who screen positive to intervention services (4)[A].
- Tertiary prevention: IPV reduced by alcoholism treatment for partner; intense advocacy interventions of >12 hours (1)[A]
- Suicide: access to mental health services, improved family and community support, development of healthy coping and problem-solving skills (CDC)
- USPSTF recommends screening adults for depression when depression care supports are in place to ensure accurate diagnosis, effective treatment, and follow-up (4)[A].
- Dating violence: self-reported dating violence reduced by school- and community-based programs for prevention of dating violence (1)[A]

**Alert**

**Poisonings (CDC):** In response to the opioid epidemic, the CDC Guideline for Prescribing Opioids for Chronic Pain—United States, March 2016 was released to **improve prescribing practices**, to aid in early identification of those at high risk for addiction, and to prevent opiate and heroin addiction and deaths.

- Prevent and treat opioid abuse: prescription drug monitoring programs; state prescription drug laws; insurance strategies (prior authorization, quantity limits, drug utilization review); prescribing practice quality improvement programs; substance abuse counseling and
In April 2018, the U.S. Surgeon General issued an advisory emphasizing the importance of the overdose-reversing drug naloxone.

Consider use of naloxone to counter the effects of opioid overdose.

Multiple doses of naloxone may be required because the duration of many opioids is greater than that of naloxone.

Follow acute care guidelines and call 911; may contact Poison Control Center hotline after discovered ingestion of toxin for recommendations (5)[A]

**ongoing care**

**Complications**

Social burden of injury: loss of productivity, emotional loss, nonmedical expenditures, reduced quality of life, litigation, rehabilitation, mental health costs, altered family and peer relationships, chronic pain, substance use and abuse, changes in lifestyle (1) (CDC)

**References**

**Additional Reading**

**Codes**
ICD10

- T14.90 Injury, unspecified
- T14.8 Other injury of unspecified body region
- R29.6 Repeated falls

CLINICAL PEARLS

- Injury and violence are predictable and preventable.
- Unintentional injury is a leading cause of death in the United States.
- Injury is the primary source of lost years of productive life for individuals age <44 years.
- MVAs cause most deaths in children and adolescents.
- Opioid overdose is increasing as a serious cause of unintentional injury and death.
BASICS

DESCRIPTION
- Difficulty initiating or maintaining sleep or nonrestorative sleep despite adequate opportunity and circumstances for sleep
- Causes at least one of the following forms of daytime impairment related to nighttime sleep difficulty:
  - Fatigue or malaise
  - Attention, concentration, or memory impairment
  - Social or vocational dysfunction or poor school performance
  - Mood disturbance or irritability
  - Daytime sleepiness
  - Motivation, energy, or initiative reduction
  - Proneness for errors or accidents at work or while driving
  - Tension, headaches, or gastrointestinal symptoms in response to sleep loss
  - Concerns or worries about sleep

EPIDEMIOLOGY
- Predominant age: increases with age
- Predominant sex: female > male (5:1)

Prevalence
- Most common sleep disorder
- Insomnia (transient and chronic): 5–35% of the population; 10–15% associated with daytime impairment
- Chronic insomnia: 10% middle-aged adults; 1/3 of people >65 years

ETIOLOGY AND PATHOPHYSIOLOGY
- Transient/intermittent (<30 days) and short-term (<3 months)
  - Usually caused by an identifiable stressor
    - Stress/excitement/bereavement
    - Shift work
    - Medical illness
    - High altitude
  - Can lead to chronic insomnia
- Chronic (>3 months)
  - Usually not due to one single cause
  - Medical: gastroesophageal reflux disease, sleep apnea, chronic pain, congestive heart failure, Alzheimer disease, Parkinson disease, chronic fatigue syndrome, irritable bowel syndrome
  - Psychiatric: mood, anxiety, psychotic disorders
  - Primary sleep disorder: idiopathic, psychophysiological (heightened arousal and learned sleep-preventing associations), paradoxical (sleep state misperception)
– Circadian rhythm disorder: irregular pattern, jet lag, delayed/advanced sleep phase, shift work
– Environmental: light (liquid crystal display [LCD] clocks), noise (snoring, household, traffic), movements (partner/young children/pets)
– Behavioral: poor sleep hygiene, adjustment sleep disorder
– Substance induced
– Medications: antihypertensives, antidepressants, corticosteroids, levodopa-carbidopa, phenytoin, quinidine, theophylline, thyroid hormones

RISK FACTORS
● Age
● Female gender
● Medical comorbidities
● Unemployment
● Psychiatric illness
● Impaired social relationships
● Lower socioeconomic status
● Shift work
● Separation from spouse or partner
● Drug and substance abuse
● Family or personal history of insomnia

GENERAL PREVENTION
● Practice consistent sleep hygiene:
  – Fixed wake-up times and bedtimes regardless of amount of sleep obtained (weekdays and weekends)
  – Go to bed only when sleepy
  – Avoid naps
  – Sleep in a cool, dark, quiet environment.
  – No activities or stimuli in bedroom associated with anything but sleep or sex
  – 30-minute wind-down time before sleep
  – If unable to sleep within 20 minutes, move to another environment and engage in quiet activity until sleepy
● Limit caffeine intake to mornings.
● No alcohol after 4 pm
● Fixed eating times
● Avoid medications that interfere with sleep
● Regular moderate exercise (more than 4 hours prior to bedtime)

COMMONLY ASSOCIATED CONDITIONS
● Psychiatric disorders
● Painful musculoskeletal conditions
● Obstructive sleep apnea
● Restless leg syndrome
● Drug or alcohol addiction/dependence
DIAGNOSIS

HISTORY
- Daytime sleepiness and napping
- Unintended sleep episodes (driving, working)
- Insomnia history
  - Duration, time of problem
  - Sleep latency, difficulty in maintaining sleep (repeated awakening), early morning awakening, nonrestorative sleep, or patterns (weekday vs. weekend, with or without bed partner, home vs. away)
- Sleep hygiene
  - Bedtime/wakening time
  - Physical environment of sleep area: LED clocks, TV, room lighting, ambient noise
  - Activity: nighttime eating, exercise, sexual activity
  - Intake: caffeine, alcohol, herbal supplements, diet pills, illicit drugs, prescriptions, over-the-counter (OTC) sleep aids
- Symptoms or history of depression, anxiety, obsessive-compulsive disorder, or other major psychological symptomatology
- Symptoms of restless leg syndrome and periodic limb movement disorder
- Symptoms of heightened arousal
- Snoring and other symptoms of sleep apnea
- Symptoms or history of drug or alcohol abuse
- Current medication use
- Chronic medical conditions
- Acute change or stressors such as travel or shift work
- Sleep diary: sleep log for 7 consecutive days

PHYSICAL EXAM
No association with specific findings on physical examination

DIFFERENTIAL DIAGNOSIS
- Sleep-disordered breathing such as obstructive sleep apnea
- Central nervous system hypersomnias (e.g., narcolepsy)
- Circadian rhythm sleep disturbances
- Sleep-related movement disorders (e.g., restless leg syndrome)
- Substance abuse
- Insomnia due to medical or neurologic disorder
- Mood and anxiety disorders such as depression or anxiety

DIAGNOSTIC TESTS & INTERPRETATION
Diagnostic testing usually not required; consider polysomnography if sleep apnea or periodic limb movement disorder is suspected (I)[C].

Initial Tests (lab, imaging)
Routine laboratory testing not recommended. Testing to consider based on history and physical exam to evaluate for comorbid conditions.

Diagnostic Procedures/Other
Polysomnography or multiple sleep latency test not routinely indicated but may be considered if
- Initial diagnosis is uncertain.
- Treatment interventions have proven unsuccessful.

**TREATMENT**

- Transient and short-term insomnia
  - May use medications for short-term use only; hypnotic sedatives favored
  - Self-medicating with alcohol can increase awakenings and sleep-stage changes.
- Chronic insomnia
  - Treatment of underlying condition (major depressive disorder, generalized anxiety disorder, medications, pain, substance abuse)
  - Advise good sleep hygiene.
  - Cognitive-behavioral therapy is first-line treatment for chronic insomnia, especially in >60 years population, especially when sedatives are not advantageous (2)[A].
  - Behavioral therapy is an effective treatment for insomnia and a potentially more effective long-term treatment than pharmacotherapy (3)[B].
  - Ramelteon is the only agent without known abuse potential (4)[B].

**MEDICATION**

- Reserved for transient and short-term insomnia such as with jet lag, stress reactions, transient medical condition
- Nonbenzodiazepine hypnotics
  - Act on benzodiazepine receptor, so have abuse potential
  - Zaleplon (Sonata) 5 to 20 mg; half-life 1 hour
  - Zolpidem (Ambien) 5 to 10 mg (males); 5 mg (females); half-life 2.5 to 3.0 hours
  - Zolpidem (Ambien CR) 6.25 to 12.50 mg (males); 6.25 mg (females); half-life 2.5 to 3.0 hours
  - Eszopiclone (Lunesta) 1 to 3 mg; half-life 6 hours
- Benzodiazepine hypnotics
  - Short acting
    - Triazolam (Halcion) 0.25 mg; half-life 1.5 to 5.5 hours
  - Intermediate acting
    - Temazepam (Restoril) 7.5 to 30.0 mg; half-life 8.8 hours
    - Estazolam (Prosom) 1 to 2 mg; half-life 10 to 24 hours
  - Long acting
    - Flurazepam (Dalmane) 15 to 30 mg; half-life 40 to 100 hours
    - Quazepam (Doral) 7.5 to 15.0 mg; half-life 39 hours (parent drug), 73 hours (active metabolite)
- Contraindications/precautions are as follows:
  - Not indicated for long-term treatment due to risks of tolerance, dependency, daytime attention and concentration compromise, incoordination, rebound insomnia
  - Long-acting benzodiazepines associated with higher incidence of daytime sedation and motor impairment
  - Avoid in elderly, pregnant, breastfeeding, substance abusers, and patients with suicidal or parasuicidal behaviors.
– Avoid in patients with untreated obstructive apnea and chronic pulmonary disease.
– No good evidence for benzodiazepines for patients undergoing palliative care (4)[A]
– Nonbenzodiazepine receptor agonists may occasionally induce parasomnias (sleepwalking, sleep eating, sleep driving).

Melatonin receptor agonist
– Ramelteon (Rozerem) 8 mg; half-life 1.0 to 2.6 hours
  - Recommended as first-line pharmacologic treatment option per AASM consensus
  - Effective to reduce sleep time onset for short- and long-term use in adults, without abuse potential; no comparative studies with older agents have been completed. Onset of effect may take up to 3 weeks.

Sedating antidepressants
– Doxepin (Silenor) 10 to 50 mg; half-life 15 hours
  - Only antidepressant with FDA approval for insomnia
  - New formulation of medication is available at dosage 3 to 6 mg QHS.
– Trazodone (Oleptro) 25 to 200 mg; half-life 3 to 9 hours
– Mirtazapine (Remeron) 7.5 to 15.0 mg; half-life 20 to 40 hours
– Amitriptyline (Elavil) 25 to 100 mg; half-life 10 to 26 hours

Orexin receptor agonists
– Suvorexant (Belsomra) 10 to 20 mg; half-life 12 hours

Sedating antihistamines are not recommended and should be used conservatively for insomnia due to insufficient evidence of efficacy and significant concerns about risks of these medications.

Evidence for use of antipsychotics is weak. They should only be prescribed if the patient has a concurrent psychiatric diagnosis warranting their use.

Geriatric Considerations
Caution (risk of falls and confusion) when prescribing benzodiazepines or other sedative hypnotics; if absolutely necessary, use short-acting nonbenzodiazepine agonists at half the dosage or melatonin agonists for short-term treatment.

COMPLEMENTARY & ALTERNATIVE MEDICINE
– Melatonin: decreases sleep latency when taken 30 to 120 minutes prior to bedtime, but there is no good evidence for efficacy in insomnia, and long-term effects are unknown (5)[B]
– Valerian: Inconsistent evidence supporting efficacy and its slow onset of action (2 to 3 weeks) makes it unsuitable for the acute treatment of insomnia.
– Acupuncture: May improve sleep quality
– Antihistamines: insufficient evidence; should not be recommended for use
– Cognitive-behavioral therapy (including relaxation therapy): effective and considered more useful than medications; recommended initial treatment for patients with chronic insomnia; no improvement of efficacy when combined with medication
– Mindfulness awareness practices: improved sleep quality and sleep-related daytime impairment for older adults per small randomized trial
– Behavioral interventions such as stimulus control therapy, sleep restriction, relaxation training may all be effective
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
● Daily exercise improves quality of sleep and may be more effective than medication.
● Avoid exercise within 4 hours of bedtime.

Patient Monitoring
● Reassess need for medications periodically; avoid standing prescriptions.
● Caution patients that nonbenzodiazepine agonists (zolpidem, zaleplon, eszopiclone), as well as benzodiazepines, can be habit forming.
● Studies suggest an association between receiving a hypnotic prescription and a >3-fold increase in hazards of death, even when prescribed <18 pills per year (6)[B].

DIET
● Avoid caffeine or reserve for morning only.
● Avoid heavy late-night snacks (light snack at bedtime may help).
● Avoid alcohol within 6 hours of bedtime.

PROGNOSIS
● Situational insomnia should resolve with time.
● Treatment of underlying etiology and consistent sleep hygiene are the mainstays of treatment.

COMPLICATIONS
● Transient insomnia can become chronic.
● Daytime sleepiness, cognitive dysfunction
● Pulmonary hypertension if chronic sleep apnea left untreated
● Sleep apnea may lead to hypertension, stroke, or cardiac ischemia.

ADDITIONAL READING
SEE ALSO
- Anxiety (Generalized Anxiety Disorder); Depression; Fibromyalgia; Sleep Apnea, Obstructive
- Algorithms: Anxiety; Insomnia, Chronic; Restless Legs Syndrome

CODES

ICD10
- G47.00 Insomnia, unspecified
- F51.02 Adjustment insomnia
- F51.01 Primary insomnia

CLINICAL PEARLS
- Treatment of underlying etiology of the insomnia and consistent sleep hygiene are key.
- Most medications are indicated for short-term use only.
- Sedative hypnotics are not recommended in the elderly because risks may outweigh benefits.
- Patients with chronic insomnia benefit from sleep hygiene education and cognitive-behavioral therapy.
INTELLECTUAL DISABILITY (INTELLECTUAL
DEVELOPMENTAL DISORDER)
Jennifer L. Ayres, PhD

BASICS
- A global deficit in cognitive functioning evidenced by a significant difference in mental and chronologic ages (IQ) and significantly impaired adaptive functioning (1).
- The term “mental retardation” was deleted from the DSM-5 and replaced with “intellectual disability” (ID) or “intellectual developmental disorder.” The term “mental retardation” is pejorative and insensitive and should be avoided.
- Although cognitive issues typically have a pervasive impact, patients with ID display highly variable levels of functioning and subsequent service needs.
- Tailor evaluation and treatment to individual needs.

DESCRIPTION
- ID is defined as an IQ ≤70 ± 5 and a significant impairment in intellectual functioning. This include verbal and nonverbal reasoning, planning, academic learning, problem solving, and experiential learning. Intellectual function is confirmed by IQ testing and clinical assessment (1).
- A diagnosis of ID also requires deficits in adaptive functioning, such as communication, socialization, and independent living (1).
- By definition, ID is a neurodevelopmental disorder that is typically present from birth or recognized during early childhood because developmental milestones are delayed (1).
- ID is currently subgrouped according to adaptive function and level of needed support: mild (typical development in some domains, mild impairment in others), moderate (skills are markedly behind typically developing, same-age peers), severe (skills quite limited compared to peers), profound (limited awareness of concepts, language; dependent on others for adaptive functioning) (1).
- The three most common causes of ID are Down syndrome, fragile X syndrome, and fetal alcohol syndrome (FAS).
- If ID reflects a loss of previously acquired intellectual skills, consider a comorbid neurocognitive disorder.
- Stereotypes of people with ID (e.g., always happy, poor prognosis, unable to function independently) have been categorically refuted. People with ID show levels of functional variability that parallels the non-ID population.
- Under the Individuals with Disabilities Education Act (IDEA), caregivers should familiarize themselves with their child’s legal rights to facilitate coordination of services with the school district.
- Under the Americans with Disabilities Act (1990), people with ID cannot be discriminated against based on their disability, and employers are legally required to ensure that appropriate accommodations are in place.

ALERT
For some causes of ID, prenatal testing is available.
EPIDEMIOLOGY

Incidence
- 1 of 6 children (2)
- Predominant sex: male > female: 1.6:1 for mild ID, 1.2:1 for severe ID (1)

Prevalence
In the United States, 1% of the general population. The prevalence of severe ID is 6/1,000 (1).

ETIOLOGY AND PATHOPHYSIOLOGY

Causes:
- Maternal substance abuse (e.g., alcohol); FAS is a leading environmental cause of ID.
- Maternal infections: TORCH viruses (toxoplasma, other infections, rubella, cytomegalovirus, and herpes simplex virus)
- Down syndrome
- Sex chromosome abnormalities: fragile X, Turner syndrome, Klinefelter syndrome
- Autosomal dominant conditions: neurocutaneous syndromes (e.g., neurofibromatosis, tuberous sclerosis)
- Autosomal recessive conditions:
  - Amino acid metabolism (e.g., phenylketonuria, maple syrup urine disease)
  - Carbohydrate metabolism (e.g., galactosemia, fructosuria)
  - Lipid metabolism
  - Tay-Sachs disease
  - Gaucher disease
  - Niemann-Pick disease; mucopolysaccharidosis
  - Purine metabolism (e.g., Lesch-Nyhan disease)
  - Other (e.g., Wilson disease)

- Maternal medications (e.g., isotretinoin, Dilantin)

Perinatal factors:
- Prematurity
- Birth injuries
- Perinatal anoxia

- Postnatal factors:
  - Childhood diseases (e.g., meningitis, encephalitis, hypothyroidism, seizure disorders)
  - Trauma (e.g., accidents, physical abuse, hypoxia)
  - Severe deprivation
  - Poisoning (e.g., lead, carbon monoxide, household products)

Genetics
A number of genetic and epigenetic causes are known, and more are under investigation.

RISK FACTORS
- Maternal substance abuse during pregnancy
- Maternal infection during pregnancy
- For some causes, family history

GENERAL PREVENTION
- Reduce alcohol and drug use by pregnant women.
- Prenatal folic acid supplementation
COMMONLY ASSOCIATED CONDITIONS
- Seizures
- Mood disorders
- Behavioral disorders
- Constipation

DIAGNOSIS
The diagnosis of ID requires a thorough assessment conducted by an appropriately credentialed mental health professional who is formally trained and licensed to conduct appropriate psychodiagnostic testing.

HISTORY
- Children with profound/severe ID are typically diagnosed at birth or during the newborn period. They may have pathognomonic dysmorphic features.
- Children with ID are often identified because they fail to meet motor/language milestones.

PHYSICAL EXAM
Certain morphologic features suggest a specific etiology for ID (e.g., microcephaly).

DIFFERENTIAL DIAGNOSIS
- Auditory, visual, and/or speech/language impairment
- Autism spectrum disorder (language and social skills are more affected than other cognitive abilities); however, 75% of individuals with an autistic disorder may meet criteria for a comorbid diagnosis of ID.
- Expressive/receptive language disorders
- Cerebral palsy
- Brain tumors
- Emotional/behavioral disturbance
- Learning disorders (reading, math, written expression)
- Auditory/sensory processing difficulties
- Lack of environmental opportunities for appropriate development

DIAGNOSTIC TESTS & INTERPRETATION
- Visual and hearing tests to rule these out as the cause of impairment and to provide an assessment of visual and auditory functioning (often impaired in children and adults with ID)
- Formal testing of intellectual and adaptive functioning:
  - A child’s communication skills must be considered in test selection. For example, a patient with auditory processing issues/limited expressive/receptive language skills may need to be assessed using a nonverbal IQ test, such as the Leiter-R, Test of Nonverbal Intelligence, or other nonverbal measures.
  - Commonly used intelligence tests (e.g., Bayley Scales of Infant Development, Stanford-Binet Intelligence Scale, Wechsler Intelligence Scales) are determined by age/developmental level.
  - Common tests of adaptive functioning include the Vineland Adaptive Behavior Scales, 2nd ed. and Adaptive Behavior Assessment System, 2nd ed. These tests assess areas of functioning such as age-appropriate communication, social skills, activities of daily living,
and motor skills.
- Metabolic screening as indicated by history and physical exam or if no newborn screening was previously performed (3).

**Initial Tests (lab, imaging)**
- Lead levels (3)[B]
- Thyroid-stimulating hormone if systemic features are present or no newborn screening was done (3)[B]
- Routine cytogenetic testing (karyotype) (3)[B]:
  - Fragile X screening (FMR1 gene), particularly with a family history of ID
  - Rett syndrome (MECP2 gene) in women with unexplained moderate to severe ID (3)
- Molecular screening (e.g., array comparative genomic hybridization) is increasing in use.
- Neuroimaging (MRI more sensitive than CT) is routinely recommended. The presence of physical findings (microcephaly, focal motor deficit) increase yield (3)[B].
- MRI may show mild cerebral abnormalities but is unlikely to establish etiology of ID.

**Follow-Up Tests & Special Considerations**
Electroencephalography is not routinely used unless a specific epileptiform diagnosis is present (3)[C].

---

### TREATMENT

- Tailor early intervention services to individual needs.
- Caregiver support, including:
  - Train caregiver(s) to address behavioral issues, discipline, and social development.
  - Encourage caregivers to create a structured home environment based on the child’s developmental level and specific needs rather than routine age-appropriate expectations.
  - Offer caregiver(s) an opportunity to address their reactions to the diagnosis and their child’s special needs.
  - Inform caregivers about advocacy groups and available resources (4).
  - Encourage caregiver(s) to seek social support to increase their own overall sense of well-being.
  - Encourage caregivers to intermittently seek respite care to promote self-care.
- Individualized education plans, social skills, and behavioral plans/training
- Refer to job training programs and independent living opportunities, if appropriate.
- Note changes in behavior, which may be indicative of pain/illness, particularly in individuals with limited communication skills.
- Assess for abuse and neglect.

### MEDICATION
Medication may be appropriate for comorbid conditions (e.g., anxiety, ADHD, depression).

---

### ONGOING CARE
Match provider communication of procedures, results, and treatment recommendations to patient level of cognitive functioning and receptive language skills.
Most patients with mild ID are fully capable of understanding information when provided at the appropriate level.

Provide oral and written explanations directly to the patient instead of solely to caregivers. Respect patient dignity at all times. Provide honest information, respond to patient’s questions with respect, and do not infantilize the patient due to the ID.

FOLLOW-UP RECOMMENDATIONS
Link to community-based resources for job training, independent living, caregiver support, school-based services

Patient Monitoring
- A quality of life assessment provides information about a patient’s general sense of well-being and life satisfaction. Quality of life may be difficult to assess when significant behavioral issues confound an individual’s self-report and socialization.
- Vision testing at least once before age 40 years (age 30 years in Down syndrome) and every 2 years thereafter
- Hearing evaluations every 5 years after age 45 years (every 3 years throughout life in Down syndrome)
- Screen for sexual activity and offer contraception and testing for STIs as appropriate.
- Screen annually for abuse and neglect, more frequently if behavior change is noted. Report abuse/neglect to appropriate protective agencies.
- Dysphagia and aspiration are common; consider speech pathology evaluation and swallowing study.

DIET
No restrictions, except in cases of metabolic and storage disorders (e.g., phenylketonuria)

PATIENT EDUCATION
- The Arc: www.thearc.org
- American Association on Intellectual and Developmental Disabilities: www.aaidd.org
- Family support groups (Parent to Parent, Local Down Syndrome, or Autism Association)
- Special Olympics: www.specialolympics.org

PROGNOSIS
- Although ID is a lifelong diagnosis, most individuals with ID are capable of fulfilling, purposeful lives that include career, independent living, participating in a committed relationship, and becoming a parent.
- The level of severity and support needed may vary over the course of the individual’s life.

COMPLICATIONS
- Constipation is a commonly overlooked problem and can lead to significant morbidity.
- Polypharmacy, often associated with psychototropic medication use to control behaviors, should be addressed to minimize adverse side effects.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- F79 Unspecified intellectual disabilities
- F70 Mild intellectual disabilities
- F71 Moderate intellectual disabilities

CLINICAL PEARLS

- “Mental retardation” is an insensitive and disrespectful term that should not be used. ID or intellectual developmental disorder is preferred.
- Multiple factors (including appropriateness of school placement/special education services, exposure to early intervention, behavioral therapy, parent training, self-esteem, and social skills) influence overall functional ability for individuals with ID.
- Children with developmental disabilities are at higher risk of abuse.
- The diagnosis of ID should be confirmed through psychodiagnostic testing by an appropriately licensed professional.
INTERSTITIAL CYSTITIS
Montiel T. Rosenthal, MD ● Sarah R. Hollis, MD

BASICS

DESCRIPTION

- A condition of pain or discomfort in the bladder associated with a need to urinate frequently and urgently
- A disease of unknown cause, probably representing a final common pathway from several etiologies
- Likely, pathogenesis is disruption of urothelium, impaired lower urinary tract defenses, and loss of bladder muscular wall elasticity. The symptoms in many patients are insidious, and the disease progresses for years before diagnosis is established.
- Newer research implicates urine and serum inflammatory proteins (such as IL-8 and chemokines CXCL-1 and CXCL-10) antiproliferative factor, nerve growth factor, epidermal growth factor, heparin-binding epidermal growth factor, glycosaminoglycans, and bladder nitric oxide as contributing factors.
- Mild: normal bladder capacity under anesthesia; ulceration, cracking, or glomerulation of mucosa (or not) with bladder distention under anesthesia; no incontinence; symptoms wax and wane and may not progress. This type of interstitial cystitis is a bladder/pelvic hypersensitivity problem.
- Severe: progressive bladder fibrosis; small true bladder capacity under anesthesia; poor bladder wall compliance. In 5–10% of cases, Hunner ulcers present at cystoscopy; may have overflow incontinence and/or chronic bacteriuria unresponsive to antibiotics
- When examined under scanning electron microscope, patients with interstitial cystitis/bladder pain syndrome (IC/BPS) were found to have defects of umbrella cell integrity of which the severity of damage coincided with severity of symptoms.
- System(s) affected: renal/urologic
- Synonym(s): urgency frequency syndrome; IC/BPS

Pregnancy Considerations

Unpredictable symptom improvement or exacerbation during pregnancy; no known fetal effects from interstitial cystitis; usual problems of unknown effect on fetus with medications taken during pregnancy

EPIDEMIOLOGY

- Occurs predominantly among whites
- Predominant sex: female > male (10:1)
- Patients <30 years have predominant symptoms: dysuria, frequency, urinary urgency, pain in external genitals, and dyspareunia, and those >60 years of age more commonly have nocturia, urinary incontinence, or Hunner ulcer disease.
- Predominant age
  - Mild: 20 to 40 years
  - Severe: 20 to 70 years

Pediatric Considerations
• <10 years old and again at 13 to 17 years
• Daytime enuresis, dysuria without infection

Prevalence
In the United States:
• Up to 1 million affected, but many cases likely are unreported
• 0.052% but may be higher, up to 10%

ETIOLOGY AND PATHOPHYSIOLOGY
• Unknown but is not primarily psychosomatic
• Possible causes
  – Subclinical urinary infection
  – Damage to glycosaminoglycan mucus layer increasing bladder wall permeability to irritants such as urea
  – Autoimmune
  – Mast cell histamine release
• Neurologic upregulation/stimulation

RISK FACTORS
Unknown

COMMONLY ASSOCIATED CONDITIONS
• Fibromyalgia
• Allergies
• Chronic fatigue syndrome
• Depression
• Vulvodynia
• Sexual dysfunction
• Sleep disturbance
• Migraines
• Syncope
• Dyspepsia
• Chronic prostatitis
• Chronic pelvic pain
• Irritable bowel syndrome
• Anal/rectal disease
• Chronic scrotal pain

DIAGNOSIS
• Frequent, urgent, relentless urination day and night; >8 voids in 24 hours
• Pain with full bladder that resolves with bladder emptying (except if bacteriuria is present)
• Urge urinary incontinence if bladder capacity is small
• Sleep disturbance
• Dyspareunia, especially with full bladder
• Secondary symptoms from chronic pain and sleeplessness, especially depression

HISTORY
Pelvic Pain and Urgency/Frequency patient symptom scale: self-reporting questionnaire for screening potential interstitial cystitis patients (http://www.wgcaobgyn.com/files/urgency_frequency_pt_symptom_scale.pdf)

Frequent urinary tract infections, vaginitis, or symptoms during the week before menses

PHYSICAL EXAM
- Perineal/prostatic pain in men
- Anterior vaginal wall pain in women

DIFFERENTIAL DIAGNOSIS
- Uninhibited bladder (urgency, frequency, urge incontinence, less pain, symptoms usually decrease when asleep)
- Urinary infection: cystitis, prostatitis
- Bladder neoplasm
- Bladder stone
- Neurologic bladder disease
- Nonurinary pelvic disease (sexually transmitted infections, endometriosis, pelvic relaxation)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Urinalysis: normal except with chronic bacteriuria (rare)
- Urine culture from catheterized specimen: normal except with chronic bacteriuria (rare) or partial antibiotic treatment
- Urine cytology
  - Normal: reserve for men >40 years old and women with hematuria

Diagnostic Procedures/Other
- Cystoscopy (especially in men >40 years old or women with hematuria)
  - Bladder wall visualization
  - Hydraulic distention: no improved diagnostic certainty over history and physical alone
  - No role for urodynamic testing
- Intravesical lidocaine can help to pinpoint the bladder as the source of pain in patients with pelvic pain; this can be both diagnostic and therapeutic.
- Potassium sensitivity test
  - Insert catheter, empty bladder, instill 40 mL H₂O over 2 to 3 minutes, rank urgency on scale of 0 to 5 in intensity, drain bladder, instill 40 mL potassium chloride (KCl) 0.4 mol/L solution.
  - If immediate pain, flush bladder with 60 mL H₂O and treat with bladder instillations.
  - If no immediate pain, wait for 5 minutes and rate the urgency and pain.
- If urgency or pain >2, treat as above.
- Pain or urgency >2 is considered a positive test and strongly correlates with interstitial cystitis if no radiation cystitis or acute bacterial cystitis is present.
- High resolution T₁ weighted magnetic resonance imaging (MRI) and fMRI can assist with elucidating chronic pelvic pain, whereas contrast enhanced bladder wall MRI can help further distinguish pelvic hypersensitivity, IC/BPS, and IC/BPS with Hunner lesions (1).
Test Interpretation

- Nonspecific chronic inflammation on bladder biopsies
- Urine cytology negative for dysplasia and neoplasia
- Possible mast cell proliferation in mucosa

TREATMENT

GENERAL MEASURES

- Appropriate health care: outpatient
- Self-care (eliminate foods and liquids that exacerbate symptoms on individual basis, fluid management) (2)[C]
- Biofeedback bladder retraining (2)[C]

MEDICATION

- Randomized controlled trials of most medications for interstitial cystitis demonstrate limited benefit over placebo; there are no clear predictors of what will benefit an individual. Prepare the patient that treatment may involve trial and error.
- Behavioral therapy combined with oral agents found improved outcomes compared to medications alone.
- Intravesical injections of botulinum toxin are not effective in the treatment of ulcer-type interstitial cystitis.

First Line

- Note: American Urological Association consensus states medicines should be considered second-line therapy after patient education, pain management, general relaxation, stress reduction, behavior modification, and self-care (2)[C].
- Pentosan polysulfate (Elmiron) 100 mg TID on empty stomach; may take several months (3 to 6) to become effective; rated as modestly beneficial in systematic drug review (only Food and Drug Administration-approved treatment for interstitial cystitis)
- Amitriptyline: most effective at higher doses (≥50 mg/day); however, initiate with lower doses to minimize side effects.
- Hydroxyzine 25 to 50 mg HS
- Sildenafil 25 mg/day (3)[B]
- Cimetidine 400 mg BID (3)[C]
- Triple-drug therapy: 6 months of pentosan, hydroxyzine, doxepin
- Antibacterials for bacteriuria
- Oxybutynin, hyoscyamine, tolterodine, and other anticholinergic medications decrease frequency.
- Prednisone or bladder submucosal steroid injections (only for ulcerative lesions)
- Montelukast has shown some benefit.
- Nonsteroidal anti-inflammatory drugs for pain and any inflammatory component
- Bladder instillations
  - Lidocaine, sodium bicarbonate, and heparin or pentosan polysulfate sodium
  - Dimethyl sulfoxide (DMSO) every 1 to 2 weeks for 3 to 6 weeks and then PRN
  - Heparin sometimes added to DMSO
  - Intravesical liposomes
– Other agents: steroids, silver nitrate, oxychlorosene (Clorpactin)
– 2% adelmidrol + 0.1% hyaluronate
– Contraindication: no anticholinergics for patients with close-angle glaucoma

Second Line
- Cystoscopy under anesthesia with hydrodistention (3)[B]
- Treatment of Hunner lesions if found

Third Line
- Phenazopyridine, a local bladder mucosal anesthetic, usually is not very effective.
- Intravesicular injection of botulinum type A for nonulcer interstitial cystitis

Fourth Line
- Cyclosporin A (2)[C]
- Hyaluronic acid instillations (4)[C]
- Chondroitin sulfate instillations (single or in combination with hyaluronic acid) have shown mixed results (4)[C].

ISSUES FOR REFERRAL
- Need for clarity with respect to diagnosis
- Surgical intervention

ADDITIONAL THERAPIES
Myofascial physical therapy (targeted pelvic, hip girdle, abdominal trigger point massage) (5)[B]

SURGERY/OTHER PROCEDURES
- Hydraulic distention of bladder under anesthesia: symptomatic but transient relief
- Cauterization of bladder ulcer
- Augmentation cystoplasty to increase bladder capacity and decrease pressure with or without partial cystectomy. Expected results in severe cases: much improved, 75%; with residual discomfort, 20%; unchanged, 5%
- Urinary diversion with total cystectomy only if disease is completely refractory to medical therapy
- Sacral neuromodulation
- Transurethral electro- or laser fulguration (effective for Hunner lesions). Pain relief may persist from several months to 2 years (4)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE
Guided imagery

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Not specifically needed unless symptoms are unresponsive to treatment

DIET
- Variable effects from person to person
Common irritants include caffeine, chocolate, citrus, tomatoes, carbonated beverages, potassium-rich foods, spicy foods, acidic foods, and alcohol.

**PATIENT EDUCATION**

**PROGNOSIS**
- Mild: exacerbations and remissions of symptoms; may not be progressive; does not predispose to other diseases
- Severe: progressive problems that usually require surgery to control symptoms

**COMPLICATIONS**
Severe, with long-term, continuous high bladder pressure could be associated with renal damage.

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**
- Urinary Tract Infection (UTI) in Females
- Algorithm: Pelvic Girdle Pain (Pregnancy or Postpartum Pelvic Pain)

**CODES**
ICD10
N30.10 Interstitial cystitis (chronic) without hematuria
N30.11 Interstitial cystitis (chronic) with hematuria

CLINICAL PEARLS

- The potassium sensitivity test has been the most useful in confirming an initial diagnosis of interstitial cystitis.
- Potassium sensitivity test
  - Insert catheter, empty bladder, instill 40 mL H₂O over 2 to 3 minutes, rank urgency on scale of 0 to 5 in intensity, rank pain on scale of 0 to 5 in intensity, drain bladder, and instill 40 mL KCl 0.4 mol/L solution.
  - Submucosal petechial hemorrhages and/or ulceration at the time of bladder distention and cystoscopy further support the diagnosis.
- At present, there is no definitive treatment for interstitial cystitis.
- Most patients with severe disease receive multiple treatment approaches. Regular multidisciplinary follow-up, pharmacologic therapy, avoidance of symptom triggers, and psychological and supportive therapy are all important because this disease tends to wax and wane. Monitor patients for comorbid depression.
- Empowering patients to manage their symptoms, communicate regularly with their physicians, and learn as much as they can about this disease, which may help them to optimize their outcome.
INTERSTITIAL NEPHRITIS
Narothama Reddy Aeddula, MD, FACP, FASN ● Samata Pathireddy, MD ● Subhasish Bose, MD, FASN

BASICS
DESCRIPTION
- Acute and chronic tubulointerstitial diseases result from the interplay of renal cells and inflammatory cells. Lethal or sublethal injury to renal cells leads to new local antigen expression, inflammatory cell infiltration, and proinflammatory activation and cytokines. Cytokines are produced by macrophages, lymphocytes, and renal cells (i.e., proximal tubule, vascular endothelial cells, interstitial cells, fibroblasts). The outcome is acute interstitial nephritis (AIN) or chronic interstitial nephritis (CIN).
- Central component in AIN is altered tubular function, which precedes decrements in filtration rate.
- AIN presents as acute kidney injury (AKI) after the use of offending drugs or agents (OFA) and is associated with typical findings of proteinuria, hematuria, and white cell casts. Less frequently, AIN is secondary to infections, systemic diseases, and mixed connective tissue disease (MCTD).
- System(s) affected: renal/urologic, endocrine/metabolic, immunologic
- Synonym(s): acute interstitial allergic nephritis

EPIDEMIOLOGY
Pediatric Considerations
- Children with history of lead poisoning are more likely to develop CIN as young adults.
- Tubulointerstitial nephritis with uveitis (TINU) presents in adolescent females with mean age of 15 years.

Incidence
- AIN account for 15–20% of AKI.
- Peak incidence in women 60 to 70 years of age

Geriatric Considerations
Elderly (≥65 years) have severe disease and increased risk of permanent damage given polypharmacy, specifically drug-induced AIN (87% vs. 64%), proton pump inhibitor–induced AIN (18% vs. 6%), but less AIN from autoimmune or systemic causes (7% vs. 27%) than younger adults (1)[B].

ETIOLOGY AND PATHOPHYSIOLOGY
- AIN
  - Delayed drug hypersensitivity reactions
  - Causes AKI
  - Renal dysfunction generally is partially or completely reversible, possibly reflecting the regenerative capacity of tubules with a preserved basement membrane.
  - Hypersensitivity to drugs (75%): not dose dependent. The top three drug causes were
omeprazole (12%), amoxicillin (8%), and ciprofloxacin (8%) (2)[C].
  
  - Antibiotics (e.g., penicillins, cephalosporins, sulfonamides, tetracycline, vancomycin,
    fluoroquinolones, macrolides, tuberculosis (TB) meds)
  - Proton pump inhibitors
  - Antivirals (indinavir)
  - Nonsteroidal anti-inflammatory drugs (NSAIDs) (all, including COX-2 inhibitors)
  - Diuretics (thiazide, loop, and triamterene)
  - Miscellaneous (allopurinol, H₂ blockers, diphenylhydantoin, and 5-aminosalicylates such
    as sulfasalazine [Azulfidine] and mesalamine)
  - Infections: Legionella, Leptospira, streptococci, cytomegalovirus, Mycobacterium TB (5–
    10%)
  - Autoimmune disorders (e.g., systemic lupus erythematosus (SLE), Sjögren syndrome,
    sarcoidosis, Wegener granulomatosis, cryoglobulinemia) (10–15%)
  - Toxins (e.g., snake bite venom)

- CIN
  - Follows long-term exposure to OFA (e.g., heavy metals, especially lead)
  - Often found on routine labs or evaluation for hypertension (HTN)
  - Characterized by interstitial scarring, fibrosis, and tubular atrophy, resulting in progressive
    chronic kidney disease (CKD)

**GENERAL PREVENTION**

- Early recognition and prompt discontinuation of OFA
- Avoid further nephrotoxic substances.

**COMMONLY ASSOCIATED CONDITIONS**

- CIN
  - Chronic pyelonephritis
  - Abuse of analgesics
  - Lithium use
  - Gout and gout therapy
  - Immune disorders
  - Malignancy (lymphoma, multiple myeloma)
  - Amyloidosis
  - Exposure to heavy metals (e.g., lead, cadmium)
  - Renal papillary necrosis

**DIAGNOSIS**

- AIN: suspected in a patient with nonspecific signs and symptoms of AKI (e.g., malaise, fever,
  nausea, vomiting) with an elevated serum creatinine and an abnormal urinalysis
  
  - AKI
    - Elevated creatinine, blood urea nitrogen, and electrolyte abnormalities (e.g.,
      hyperkalemia, low serum bicarbonate)
    - Decreased urine output (oliguria in 51%)
    - Signs of fluid overload or depletion
  
  - Signs of systemic allergy (e.g., fever [27%], maculopapular rash [15%], peripheral
eosinophilia [23%], arthralgias [45%] but less commonly found when NSAIDs are the OFA)
– Eosinophilia and eosinophiluria
– Urine—white blood cell (WBC), red blood cell (RBC), and white cell casts

● CIN
  – HTN
  – Decreased urine output or polyuria
  – Inability to concentrate urine
  – Polydipsia
  – Metabolic acidosis
  – Anemia
  – Fanconi syndrome

HISTORY
● Medications: Onset of AIN following drug exposure ranges from 3 to 5 days (as occurs with a second exposure to an OFA) to as long as several weeks to many months (the latter with NSAIDs, especially) (2).
● Infections: symptoms related to an associated infection or systemic condition
● TINU patients present with interstitial nephritis and uveitis and occasionally systemic findings.
● Exposure to heavy metals
● Postorgan transplant

PHYSICAL EXAM
● Increased BP
● Fluid retention/extremity swelling/weight gain
● Rash accompanying renal findings in acute AIN
● Lung crackles/rales
● Pericardial rub if uremic pericarditis

DIFFERENTIAL DIAGNOSIS
● AKI secondary to other causes:
  – Prerenal (e.g., hypovolemia, shock, sepsis, renal artery emboli)
  – Intrarenal (e.g., acute tubular necrosis, hypertensive nephropathy, diabetes mellitus nephropathy)
  – Postrenal (e.g., obstructive uropathy)
  – Some OFAs that cause AIN can produce other forms of AKI as well:
    o NSAIDs can exacerbate prerenal disease.
    o Aminoglycosides can cause acute tubular necrosis.
● CKD secondary to long-standing HTN, diabetes, and chronic pyelonephritis

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
● Chemistry
  – Elevated creatinine: seen in all patients, with 40% requiring dialysis
  – Hyperkalemia and acidosis
● Complete blood count
  – Eosinophilia (80%): NSAID-induced AIN is only associated with eosinophilia in ~15% of cases.
- Anemia
- Urinalysis with urine electrolytes
  - Hematuria (95%)
  - Mild and variable proteinuria: usually <1 g/24 hr, except in AIN associated with NSAIDs where it is higher
  - Urine sediment: WBC, RBC, white cell casts. RBC casts are rare.
  - Eosinophiluria but has no clinical utility specific for AIN (3)[C]
  - Fractional excretion of sodium (\(FE_{Na}\) >1%) indicative of tubular damage
  - Normal urinalysis does not rule out AIN.
- Chest x-ray to evaluate for pulmonary TB, sarcoidosis, and infections
- Serologies for immunologic disease (e.g., sarcoidosis, SJögren syndrome, Wegener granulomatosis, Behçet syndrome) or infectious causes (e.g., histoplasmosis, coccidioidomycosis, toxoplasmosis, Epstein-Barr virus)
  - Serum levels of angiotensin-converting enzyme and serum Ca\(^{++}\) for sarcoidosis
  - Antinuclear antibody (ANA) and dsDNA to exclude SLE
  - ANCA
  - Urinary Legionella antigen
  - C3 and C4 to evaluate for SLE and IgG4-related disease
  - Serum protein electrophoresis
  - Anti-Ro/SSA, anti-La/SSB antibodies, C-reactive protein, and rheumatoid factor to exclude SJögren syndrome
- Liver function tests: elevated serum transaminase levels in patients with associated drug-induced liver injury
- Renal US may demonstrate kidneys that are normal to enlarged in size with increased cortical echogenicity, but no reliable confirmatory US findings for AIN.
- IV pyelography (IVP) and CT scans with contrast are relatively contraindicated given nephrotoxicity and limited diagnostic yield.

**Follow-Up Tests & Special Considerations**
Patients who do not recover and with CIN should receive follow-up care to protect from further nephrotoxic therapies.

**Diagnostic Procedures/Other**
- Renal biopsy is the definitive method of establishing the diagnosis of AIN. Should be considered:
  - Patients on an OFA known to cause AIN but have normal urinalysis
  - Patients considered for steroid therapy
  - Patients not on glucocorticoid therapy and do not have recovery following cessation of the OFA
  - Patients with advanced renal failure of recent onset (<3 months)
  - Patients with any features (e.g., high-grade proteinuria) that makes AIN diagnosis uncertain
- Contraindications: Biopsy is contraindicated in bleeding diathesis, solitary kidney, end-stage renal disease (ESRD) with small kidneys, uncontrolled HTN and sepsis, or renal parenchymal infection.

**Test Interpretation**
- Acute
– Biopsy shows marked interstitial infiltrate consisting of T lymphocytes and monocytes. Eosinophils, plasma cells, and neutrophils may be found.
– Tubulitis is found when inflammatory cells invade the tubular basement membrane.
– Generally, the urinary findings will distinguish AIN from other causes (e.g., acute tubular necrosis, glomerulonephritis).

Chronic: CIN is characterized by tubular atrophy, fibrosis, and cellular infiltration with mononuclear cells.

## TREATMENT

For AIN, data on corticosteroids’ efficacy have been limited (4)[B].

### GENERAL MEASURES

- Discontinue offending agent including topical NSAIDs.
- Reduce exposure to nephrotoxic agents (e.g., furosemide, aminoglycosides).
- Supportive measures:
  - Maintain adequate hydration.
  - Symptomatic relief for fever and rash
  - Control of BP and anemia
  - Correct acidosis and electrolyte imbalances.
  - Short-term dialysis until renal recovery

### MEDICATION

- Mainstay is supportive therapy.
- If patient is on multiple OFA, a reasonable approach is substitution of the suspected drug with another medication.
- If AKI persists after removing OFA, attempt medication therapy.

#### First Line

- Unknown optimal therapy because no randomized controlled trials (RCTs) or large observational studies
- Immunosuppression if no improvement within 3 to 7 days after OFA discontinuation
- Renal biopsy to confirm AIN and to exclude others or CIN, where immunosuppressive prescription not indicated
- Prednisone 1 mg/kg/day PO or equivalent IV dose to a max of 40 to 60 mg/day for 1 to 2 weeks, beginning a gradual taper after serum creatinine has returned to near baseline for a duration of 2 to 3 months, followed by a gradual taper over 3 to 4 weeks (4)[B]. Complete recovery is noted in 49% and partial in 39% (1)[C].
  - Steroids started within 7 days of withdrawal of OFA more likely to recover than those who started later (odds ratio [OR] 6.6).

#### Second Line

- Limited experience with treating AIN in patients who are steroid dependent (i.e., relapse during prednisone taper), steroid resistant (as with NSAID-induced disease), or cannot tolerate steroids
- Mycophenolate mofetil may be considered in biopsy-proven AIN patients. Prescription may need to be continued for 1 to 3 years (5).
● Lead toxicity: Chelation may improve function.
  – Succimer 10 mg/kg (max 500 mg) PO q8h for 5 days, then q12h for 14 days, or
  – EDTA 2 g IV/IM; if IM, use with 2% lidocaine.
● SLE nephritis: steroids + cyclophosphamide or azathioprine
● Urate nephropathy: urate-lowering agents
  – Allopurinol starting at 100 mg/day, increasing to 300 mg/day to achieve serum urate level <6 mg/dL
  – Dose needs to be adjusted depending on level of renal impairment.
  – Allopurinol itself can be a cause of AIN.
  – Discontinue thiazide.
● Lithium-induced nephritis: Use amiloride as adjunct.
● Indinavir-induced nephritis: Use probenecid as adjunct.

ISSUES FOR REFERRAL
Patients presenting with AKI, proteinuria, and acid-base and/or electrolyte disorders require consultation with a nephrologist.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Patients with AKI and/or with serious electrolyte or acid-base disorders require hospitalization.

● Admission criteria/initial stabilization
  – Persistent oliguria or anuria
  – Severe acidosis and/or electrolyte abnormalities
  – ECG changes
● Discharge criteria
  – Stable vitals; correction of all electrolyte imbalances and improved epidermal growth factor receptor
  – Normal urine production

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
If patients must remain on nephrotoxic agents, measure renal function, electrolytes, and phosphorus frequently.

DIET
● Low potassium (<2 g/day)
● Low sodium
● Low protein (6)

PATIENT EDUCATION
Printed materials for patients are available at the National Kidney Disease Education Program, (866) 4-KIDNEY, https://www.niddk.nih.gov/health-information/health-communication-programs/nkdep/Pages/default.aspx.

PROGNOSIS
● If AIN is detected early (within 1 week of the rise in serum creatinine) and the OFA is
discontinued promptly, the long-term outcome is favorable; however, it is often incomplete with persistent serum creatinine noted in up to 40% of patients, especially in NSAID-induced AIN.

- Renal biopsy reveals extent of damage.
- AIN
  - Recovery within weeks to months
  - Acute dialysis is needed for 1/3 of patients before resolution.
  - Progresses to ESRD in 10% patients
- CIN: can progress to ESRD
  - Renal disease may remit in 1 year if untreated.
  - TINU has relapsing course, requiring systemic corticosteroids.
- Untreated severe AKI has 45–70% mortality.
- AIN prognosis in sarcoidosis or infection is not well described.

**COMPLICATIONS**

- Chronic tubulointerstitial disease may progress to ESRD, requiring dialysis or transplantation.
- Analgesics increase the risk of transitional cell cancers of the uroepithelium.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- N12 Tubulo-interstitial nephritis, not spcf as acute or chronic
- N10 Acute tubulo-interstitial nephritis
- N11.9 Chronic tubulo-interstitial nephritis, unspecified
CLINICAL PEARLS

- First step in treatment is to remove offending agents. Most common in elderly are proton pump inhibitors and antibiotics.
- A renal biopsy is preferred to confirm AIN.
- Immunosuppressive therapy is employed if no subsequent improvement within 3 to 7 days after discontinuation of OFA.
IRRITABLE BOWEL SYNDROME
Marie L. Borum, MD, EdD, MPH, MACP, FACG, AGAF  Karan Chawla, MD

BASICS
DESCRIPTION
● A gastrointestinal disorder characterized by
  – Chronic and/or recurrent abdominal pain or discomfort, bloating and distension, and alteration in bowel habits in the absence of an organic cause.
● May be characterized as diarrhea-predominant or constipation-predominant; may alternate between symptoms
● Synonym(s): spastic colon; irritable colon

EPIDEMIOLOGY
Irritable bowel syndrome (IBS) accounts for 30–50% of visits to gastroenterologists:
● Second only to upper respiratory infection as cause of lost workdays

Prevalence
Pooled estimate of 11% IBS prevalence internationally; ranges from South Asia (7%) to South America (21%); prevalence in North America is 12%.
● Predominant age: 20 to 39 years
● If age >50 years, consider other diagnoses.
● In the United States, female > male (2:1)
● More common in low socioeconomic communities

ETIOLOGY AND PATHOPHYSIOLOGY
● The etiology is unknown; associated with abnormalities of intestinal motility and enhanced sensitivity to visceral stimuli
● The trigger may be luminal or environmental.
● Evidence for the role of small intestinal bacterial overgrowth (SIBO) in IBS and association with antibiotic therapy is controversial; older age and female gender are predictors of SIBO in IBS patients.
● The role of food sensitivity, genetic, and psychosocial causes are also under active investigation.
● Four bowel patterns in the Rome IV classification:
  – IBS-D (diarrhea predominant); IBS-C (constipation predominant); IBS-M (mixed diarrhea and constipation); IBS-U (unclassified—symptoms cannot be categorized into one of the three subtypes)
● The utility of subtyping has been questioned. Many patients change categories/subtypes over time.

Genetics
Unknown. IBS tracks in some families. Twin studies do not, however, show a clear genetic component.
RISK FACTORS
- Other family members with similar gastrointestinal (GI) disorder
- History of childhood sexual abuse
- Sexual/domestic abuse (primarily in women)
- Depression
- Gastrointestinal infection

Pediatric Considerations
No risk to mother or fetus

GENERAL PREVENTION
See “Diet.”

COMMONLY ASSOCIATED CONDITIONS
- Chronic migraine
- Fibromyalgia
- Chronic fatigue syndrome
- Sleep disorders
- Psychiatric disorders: major depression, anxiety, somatoform disorders, and posttraumatic stress
- Chronic pelvic pain
- Temporomandibular joint dysfunction

DIAGNOSIS

HISTORY
- Rome IV criteria: recurrent abdominal pain >1 day/week, on average, in the previous 3 months with an onset >6 months before diagnosis
- Abdominal pain and at least two of the following:
  - Improvement or worsening of pain with defecation
  - Change in frequency of stools
  - Change in form (appearance) of stools
- Patient has no warning signs (red flags):
  - Age >50 years, no previous colon cancer screening and presence of symptoms
  - Recent change in bowel habit
  - Evidence of overt GI bleeding (melena or hematochezia)
  - Nocturnal pain or passage of stools
  - Unintentional weight loss
  - Family history of colorectal cancer or inflammatory bowel disease
  - Palpable abdominal mass or lymphadenopathy
  - Evidence of iron deficiency anemia on blood testing
  - Positive fecal occult blood

PHYSICAL EXAM
- Complete exam to exclude other causes
- Vital signs and general exam are typically normal.
- There is typically an absence of jaundice and organomegaly, but there may be tenderness to
palpation.

**DIFFERENTIAL DIAGNOSIS**

- Inflammatory bowel disease
- Lactose intolerance; fructose malabsorption
- Infections (Giardia lamblia, Entamoeba histolytica, Salmonella, Campylobacter, Yersinia, Clostridium difficile)
- Celiac sprue; microscopic colitis
- Laxative abuse; magnesium-containing antacids
- Hypo-/hyperthyroidism
- Pancreatic insufficiency
- Small bowel bacterial overgrowth
- Somatization; depression
- Villous adenoma
- Endocrine tumors
- Diabetes mellitus
- Radiation damage to colon or small bowel

**DIAGNOSTIC TESTS & INTERPRETATION**

- With a typical history and no warning signs (anemia or weight loss), only obtain baseline labs (complete blood count [CBC]; basic metabolic profile; stool ova and parasites; fecal leukocytes; Giardia antigen; Clostridium difficile toxin) and begin treatment.
- Plasma anti-cytolethal distending toxin B (anti-CdtB) and anti-vinculin antibodies are elevated in IBS-D and IBS-M, but not IBS-C (1).
- In patients who do not respond to treatment, further evaluation with imaging and/or endoscopy is warranted to exclude organic pathology.

**Initial Tests (lab, imaging)**

Rule out pathology specific to the patient’s symptoms:

- Diarrhea-predominant: erythrocyte sedimentation rate, CBC, tissue transglutaminase (rule-out celiac disease), thyroid-stimulating hormone (TSH), and stool for ova and parasites
- Constipation-predominant: CBC, TSH, electrolytes, calcium (screen for hyperparathyroidism) (2)
- Abdominal pain: liver function tests and amylase
- When obtained, abdominal computed tomography scan and ultrasound are generally normal.
- Consider hydrogen breath testing to exclude bacterial overgrowth.
- Consider small bowel series or video capsule endoscopy to rule out Crohn disease (typically normal).
- Sitz marker study may be used to evaluate colonic transit in patients with constipation.

**Follow-Up Tests & Special Considerations**

Consider lactulose breath test to assess for small bowel bacterial overgrowth associated with IBS.

**Diagnostic Procedures/Other**

Sigmoidoscopy/colonoscopy may be used to rule out inflammatory bowel disease or microscopic colitis.
Alert
Screen all persons >50 years of age (or those with warning signs/red flags) for colorectal cancer.

Test Interpretation
None

TREATMENT
- Goals: Relieve symptoms, improve quality of life (2)
  - Determine if diarrhea-predominant, constipation-predominant, or mixed type.
- Lifestyle modification
  - Exercising 3 to 5 times per week decreases severity (2).
  - Food diary to determine triggers (2).
  - Food found to be associated with IBS symptoms include: vegetables, legumes, fruit, tea, and fiber-rich foods, which may increase intestinal peristalsis.

MEDICATION
- Medications
  - Fiber supplementation (psyllium) increases stool bulk; does not typically relieve abdominal pain; may be used for all types (2) [B]
- Medications that improve abdominal pain, global symptoms, and symptom severity in all types:
  - Antispasmodics such as hyoscyamine 0.125 to 0.250 mg PO/SL q4h PRN and dicyclomine 20 to 40 mg PO BID can be used for all types but have adverse effects such as dry mouth, dizziness, and blurred vision (2).
  - Probiotics such as Lactobacillus, Bifidobacterium, and Streptococcus (3) [C]
- Diarrhea-predominant
  - Antidiarrheal such as loperamide 4 to 8 mg/day orally divided 1 to 3 times per day as needed to decrease stool frequency and increase stool consistency; does not help with abdominal pain; may also use diphenoxylate and atropine (2).
  - Bile acid sequestrants can be used for symptom control in patients with persistent symptoms despite use of antidiarrheals; these include cholestyramine, colestipol, and colesvelam (4).
  - Antibiotics such as 2-week course of rifaximin improve bloating, pain, and stool consistency.
  - Alosetron (Lotronex; 0.5 mg PO BID), for women with severe symptoms; associated with ischemic colitis, constipation, and death in a small number of patients.
  - Ondansetron was found to reduce symptoms severity other than pain (4).
  - Eluxadoline (75–100 mg BID) is a mixed opioid receptor agonist and antagonist that has recently been shown to relieve symptoms in diarrhea-predominant IBS; adverse effects include nausea, constipation, abdominal pain, and pancreatitis (4).
- Constipation-predominant
  - Laxatives such as polyethylene glycol may improve stool frequency but not pain.
  - Antibiotics such as neomycin and selective chloride channel activators such as lubiprostone (Amitiza) 8 mg BID can improve global symptoms and severity (2) [B].
  - Linaclotide (guanylate cyclase 2C agonist) has been shown to improve bowel function and reduces abdominal pain and overall severity in adults only (5).
– Plecanatide (3–6mg qd) was recently approved by the FDA for use in patients with constipation-predominant IBS; acts by increasing intestinal transit and fluid content (5).
– Lubiprostone is also efficacious; it works by activating chloride channels in the GI tract to increase chloride-rich fluid content in stool and assist with bowel movements (5).

**Mixed**
– Use medications to match symptoms (2).

**Treat underlying behavioral issues:**
– Tricyclic antidepressants can help control IBS symptoms in moderate to severe cases.
– Behavioral therapy helps reduce symptoms.

**ISSUES FOR REFERRAL**
– Behavioral health referral may help with management of affective or personality disorders.
– Gastroenterology referral for difficult to control cases

**ADDITIONAL THERAPIES**
Probiotics use may result in reducing IBS symptoms and decreasing pain and flatulence. There is no difference among Lactobacillus, Streptococcus, Bifidobacterium, and combinations of probiotics.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
The IBS Severity Scoring System is a validated measure to assess the severity of IBS symptoms and can help monitor response to treatment.

– IBS Severity Scoring System:
  – How severe has your abdominal pain been over the last 10 days?
  – On how many of the last 10 days did you have pain?
  – How severe has your abdominal distension (bloating, swollen, or tight) been over the last 10 days?
  – How satisfied have you been with your bowel habit (frequency, ease, etc.) over the last 10 days?
  – How much has your IBS been affecting/interfering with your life in general over the last 10 days?

**DIET**
– Diet low in fermentable oligosaccharides, disaccharides, and monosaccharides, and polyols (FODMAPs); FODMAPs are osmotic, so they may not be digested or absorbed well and could be fermented by bacteria in the intestinal tract when eaten in excess.
– A low FODMAP diet may help reduce symptoms.
  – Increase fiber slowly to avoid excess intestinal gas production.
  – Initially, consider 2 weeks of lactose-free diet to rule out lactose intolerance.
  – Avoid large meals, fatty foods, and caffeine, which can exacerbate symptoms.
  – Avoid foods that increase flatulence, including beans, onions, celery, carrots, raisins, bananas, apricots, prunes, brussels sprouts, wheat germ, pretzels, and bagels.
  – A gluten-free diet resolves symptoms for some patients (especially diarrhea-predominant
IBS) despite negative testing for celiac disease.

PATIENT EDUCATION
- IBS is not a psychiatric illness, but is a chronic condition.
- No increased risk of malignancy

PROGNOSIS
- IBS is a disorder that reduces quality of life. Many patients have behavioral health issues. IBS does not increase mortality (6).
- Expect recurrences, especially when under stress.
- Evidence suggests that “symptom shifting” occurs in some patients, whereby resolution of functional bowel symptoms is followed by the development of functional symptoms in another system (6).

REFERENCES

ADDITIONAL READING
Low FODMAP diet.

SEE ALSO
Algorithm: Diarrhea, Chronic

CODES
ICD10
- K58.9 Irritable bowel syndrome without diarrhea
- K58.0 Irritable bowel syndrome with diarrhea
CLINICAL PEARLS

- Use Rome III criteria to establish the diagnosis of IBS.
- A comprehensive history and physical exam with targeted laboratory testing can establish the diagnosis of IBS in most patients.
- Goals of treatment are to relieve symptoms and improve quality of life.
- If patients do not respond to initial treatment, consider further evaluation (including imaging and/or referral for endoscopy) to exclude organic pathology.
KAWASAKI SYNDROME
Scott P. Grogan, DO, MBA, FAAFP

BASICS

DESCRIPTION
- Kawasaki syndrome (KS) is a self-limited acute, febrile, systemic vasculitis of small- and medium-sized arteries that predominantly affects patients age 6 months to 5 years and is the most prominent cause of acquired coronary artery disease in pediatric populations.
  - Vasculitis of coronary arteries resulting in aneurysms/ectasia, further leading to myocardial infarction (MI)/ischemia or sudden death
- System(s) affected: cardiovascular, gastrointestinal, hematologic/lymphatic/immunologic, musculoskeletal, nervous, pulmonary, renal/urologic, skin/exocrine
- Synonym(s): mucocutaneous lymph node syndrome (MCLS), infantile polyarteritis, Kawasaki disease

ALERT
KS should be considered in any child with extended high fever unresponsive to antibiotics or antipyretics, rash, and nonexudative conjunctivitis.

EPIDEMIOLOGY

Incidence
- Worldwide: affects all races but most prevalent in Asia; Japan annual incidence rate 265/100,000 in children <5 years of age
- In the United States, the annual incidence in children <5 years is 19/100,000. In comparison to Caucasians, African Americans have a 1.5 times risk, and Asian Americans have a 2.5 times increased risk. Highest state incidence is in Hawaii.
- Leading cause of acquired heart disease in children in developed countries
  - Predominant age: 1 to 5 years
  - 85% of cases are children <5 years of age and 50% <2 years of age.
  - Male-to-female ratio = 1.5:1

Prevalence
- Highest to lowest prevalence: Asians > African Americans > Hispanics > Caucasians
- Seasonal variation: increased in winter and early spring in temperate places, summer in Asia, and outbreaks at 2- to 3-year intervals

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute KS causes a necrotizing arteritis in the smooth muscle layer of medium extraparenchymal arteries that destroys arterial walls into the adventitia, especially in coronary arteries.
- Inflammatory cells in the media secrete cytokines (TNF-α), interleukins 1 and 6, and matrix metalloproteases that cause fragmentation of the internal elastic lamina.
- A prominence of IgA plasma cells and IgA deposits are characteristic features and may be found in the lungs.
- As the acute process resolves, active neutrophilic inflammatory cells are succeeded by a
subacute/chronic, lymphocytic vasculitis; fibroblasts and monocytes cause tissue repair/remodeling that may cause vascular fibrosis and stenosis.
- Unknown; believed to be an exaggerated immune response to infectious agent due to the acute, self-limited nature; community-wide outbreaks; age distribution; seasonality; and laboratory features indicating respiratory route of entry

**Genetics**
- Siblings of patients in Japan have a 10- to 30-fold increased risk, and >50% develop KS within 10 days of first case; increased occurrence of KS in children whose parents also had illness in childhood
- Populations at higher risk and family link suggest a genetic predisposition.
- Single-nucleotide polymorphisms in six different genes have been implicated in KS (Fcγ receptor 2A, CASP3, HLA class II, B-cell lymphoid kinase, IPTKC, CD40).
- Coronary aneurisms are associated with variants in TGF-β signaling pathways.

**GENERAL PREVENTION**
No preventive measures available

**DIAGNOSIS**
≥5 days of fever and ≥4 of the following 5 principal clinical features; or <4 features and presence of coronary artery disease on 2D echocardiography:
- Bilateral conjunctival injection with limbic sparing
- Erythematous mouth and pharynx, tongue, and lips
- A polymorphous, generalized, erythematous rash
- Changes in the skin of the peripheral extremities
- Cervical lymphadenopathy

**Pediatric Considerations**
- Prolonged fever without rash and treated with antibiotics may cause clinicians to believe that later rash development is due to a drug reaction.
- Can be diagnosed on day 4 of illness if ≥4 principal features are present
- Incomplete KS
  - ≥5 days of fever, 2 to 3 principal clinical features, labs indicating systemic inflammation, and exclusion of other diseases
  - Incomplete cases that exhibit <4 clinical criteria often occur in infants ≤6 months of age or older children/adolescents. The frequency of coronary artery aneurysms (CAAs) is often higher in patients with missed diagnosis/delayed treatment. Therefore, in infants with prolonged fever and few or no clinical features, consider echocardiography and inflammatory labs.

**HISTORY**
- Fever is the first sign during the acute phase.
- Symptoms may not occur all at once but usually occur in close proximity.

**PHYSICAL EXAM**
- High-spiking and remittent fever for ≥5 days
  - Fever is high (102–105°F [39.4–40.5°C]) and unresponsive to antibiotics.
– May be prolonged up to 3 to 4 weeks
– Extreme irritability is a very common feature.

• Bilateral, painless, nonpurulent, conjunctival injection without corneal ulceration or edema. Limbic sparing is usually seen.
• Changes in lips and oral cavity
  – Redness and swelling of lips in the acute stage; cracking, fissuring, bleeding in subacute phase
  – Strawberry/erythematous tongue
• Extensive erythematous polymorphous rash: within 5 days of fever
  – Morbilliform is most common. May be maculopapular, scarlatiniform; can resemble erythema multiforme, erythoderma, urticarial exanthem; rarely micropustular
  – Perineal desquamation, especially in skin folds
• Extremity changes
  – Reddened palms and soles on days 3 to 5
  – Edema of hands and feet on days 4 to 7; painful induration
  – Desquamation of fingers and toes that begins in periungual area at 2 to 3 weeks
• Acute, unilateral cervical lymphadenopathy (least common symptom)
  – ≥1 lymph nodes >1.5 cm, firm, nonfluctuant, and usually with no to slight tenderness
• Cardiac exam: tachycardia, gallop rhythms, hyperdynamic precordium, innocent flow murmurs, depressed contractility

• Other organ system involvement
  – Cardiovascular: myocarditis; pericarditis (often subclinical), CAAs, and other medium-sized arterial aneurysms
  – Gastrointestinal: anorexia, abdominal pain, vomiting/diarrhea, acute gallbladder hydrops, hepatic enlargement, jaundice
  – Renal: proteinuria, sterile pyuria
  – Joints: polyarthritis of small joints in acute phase; weight-bearing joints affected after 10th day from onset of fever
  – Neurologic: irritability, aseptic meningitis, peripheral neuropathy (unilateral facial palsy), transient high-frequency hearing loss

**DIFFERENTIAL DIAGNOSIS**

• Bacterial: staphylococcal scalded-skin syndrome, toxic shock syndrome, scarlet fever, bacterial cervical lymphadenitis, Mycoplasma infection, leptospirosis, Lyme disease, Rocky Mountain spotted fever
• Viral: measles, adenovirus, Epstein-Barr virus
• Toxoplasmosis
• Reiter syndrome
• Hypersensitivity drug reactions (erythema multiforme minor, Stevens-Johnson syndrome)
• Juvenile rheumatoid arthritis
• Acrodynia (mercury poisoning)

**DIAGNOSTIC TESTS & INTERPRETATION**

• Initial workup: complete blood count with differential, urinalysis (UA)/culture, blood culture; lumbar puncture if signs of meningitis or if <90 days old
  – Leukocytosis (12,000 to 40,000 cells/mm³) with immature and mature granulocytes
  – Anemia: normochromic, normocytic
– Thrombocytosis (500,000 to >1,000,000/mm$^3$) in 2nd and 3rd week. Thrombocytopenia during acute phase is associated with CAA and MI.

- Elevated C-reactive protein (CRP) (>35 mg/L in 80% cases), erythrocyte sedimentation rate (ESR) (>60 mm/hr in 60% cases), and $\alpha_1$-antitrypsin
- Normal ESR, CRP, and PLTs after day 7 suggest diagnosis other than KS.

**ALERT**
ESR can be artificially high after intravenous immunoglobulin (IVIG) therapy.

- Hyponatremia
- Moderately elevated aspartate aminotransferase, alanine aminotransferase, $\gamma$-glutamyl transpeptidase, and bilirubin
- Decreased albumin and protein
- Cerebrospinal fluid pleocytosis may be seen (lymphocytic with normal protein and glucose).
- N-terminal brain natriuretic peptide might be elevated in acute phase, but definitive cut-off values have not been established.
- Sterile pyuria but not seen in suprapubic collection
- Nasal swab to rule out adenovirus

**Initial Tests (lab, imaging)**
- If KS is suspected, obtain ECG and echocardiogram.
  - ECG may show arrhythmias, prolonged PR interval, and ST/T wave changes.
  - Echocardiography has a high sensitivity and specificity for detection of abnormalities of proximal left main coronary artery, and right coronary artery may show perivascular brightening, ectasia, decreased left ventricular contractility, pericardial effusion, or aneurysms.
  - Repeat echocardiography frequency determined by degree of abnormal findings; more significant findings should be followed twice weekly until aneurismal progression halts.
  - Cardiac stress test if CAA seen on echocardiogram
- Baseline chest x-ray (CXR): may show pleural effusion, atelectasis, and congestive heart failure (CHF)
- Hydrops of the gallbladder may be associated with abdominal pain or may be asymptomatic.

**Diagnostic Procedures/Other**
- No laboratory study is diagnostic; diagnosis rests on constellation of clinical features and exclusion of other illnesses.
- Magnetic resonance coronary angiography is noninvasive modality to visualize coronary arteries for stenosis, thrombi, and intimal thickening (1).
- Patients with complex coronary artery lesions may benefit from coronary angiography after the acute inflammatory process has resolved; generally recommended in 6 to 12 months

**TREATMENT**
**GENERAL MEASURES**
Use antibiotics until bacterial etiologies are excluded (e.g., sepsis or meningitis).

**MEDICATION**
Optimal therapy is IVIG 2 g/kg IV over 10 to 12 hours with high-dose aspirin preferably within 7 to 10 days of fever, followed by low-dose aspirin until follow-up echocardiograms indicate a lack of coronary abnormalities.
- IVIG lowers the risk of CAA and may shorten fever duration.
- The extreme irritability often resolves very quickly after IVIG is given.

Retreatment with IVIG if clinical response is incomplete or fever persists/returns >36 hours after start of IVIG treatment
- ≥10% of patients do not respond to initial IVIG treatment. 2/3 of nonresponders respond to the second dose of IVIG.
- Nonresponders tend to have ↑ bands, ↓ albumin, and an abnormal echo.

Aspirin 80 to 100 mg/kg/day in 4 doses beginning with IVIG administration. Switch to low-dose aspirin (3 to 5 mg/kg/day) when afebrile for 48 to 72 hours, or continue until day 14 of illness. Maintain low dose for 6 to 8 weeks until follow-up echocardiogram is normal and CRP and/or ESR are normal. Continue salicylate regimen in children with coronary abnormalities, long term or until documented regression of aneurysm (2)[C].

Aspirin does not appear to reduce CAA (3)[B].

Corticosteroids have conflicting evidence for use and:
- Should not be used as first-line agent in all KS patients (1)[B]
- Should be used in conjunction with IVIG and ASA as initial treatment to decrease risk of CAAs in those at highest risk of IVIG failure (4)[A]

Contraindications
- IVIG: documented hypersensitivity, IgA deficiency, anti-IgE/IgG antibodies, severe thrombocytopenia, coagulation disorders
- Aspirin: vitamin K deficiency, bleeding disorders, liver damage, documented hypersensitivity, hypoprothrombinemia

Precautions
- No statistically significant difference is noted between different preparations of IVIG.
- High-dose aspirin therapy can result in tinnitus, decreased of renal function, and increased transaminases.
- Do not use ibuprofen in children with CAAs who are taking aspirin for antiplatelet effects.
- Significant possible interactions: Aspirin therapy has been associated with Reye syndrome in children who develop viral infections, especially influenza B and varicella. Yearly influenza vaccination thus is recommended for children requiring long-term treatment with aspirin. Delay any live vaccines for 11 months after IVIG treatment.

**Second Line**
- In patients refractory to IVIG and steroids, consider infliximab or cyclosporine (5)[B].
- Plasma exchange may decrease likelihood of CAA in IVIG nonresponders (6)[B].

**ISSUES FOR REFERRAL**
Pediatric cardiologist if abnormalities on echo or if extensive stenosis

**ADDITIONAL THERAPIES**
- Treatment and prevention of thrombosis are crucial.
- Antiplatelet agents (clopidogrel, dipyridamole), heparin, low-molecular-weight heparin, or warfarin are sometimes added to the low-dose aspirin regimen, depending on severity of CAAs.
• Clarithromycin given with IVIG may reduce relapse rates and length of hospital stay.

SURGERY/OTHER PROCEDURES
• Rarely needed; coronary artery bypass grafting for severe obstruction/recurrent MI. Younger patients have a higher mortality rate.
• Coronary revascularization via percutaneous coronary intervention for patients with evidence of ischemia on stress testing

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Normal saline (NS) for rehydration and 1/2 NS for maintenance
• Discharge if afebrile after IVIG treatment for 24 hours.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
With aneurysms, contact and high-risk sports should be avoided.

Patient Monitoring
• Repeat ECG and echocardiogram at 6 to 8 weeks. If abnormal, repeat at 6 to 12 months.
• Patients with complex coronary artery lesions may benefit from coronary angiography at 6 to 12 months.

PROGNOSIS
• Usually self-limited
• Moderate-sized aneurysms usually regress in 1 to 2 years, resolving in 50–66% of cases.
• Recurrence (3% in Japan, <1% in the United States)
• Sudden death in early adulthood (rare)

COMPLICATIONS
• 15–25% of untreated patients develop CAAs in convalescent phase.
• 2–7% of treated patients develop aneurysms. 1% develop giant aneurysms.
• Risk factors for aneurysm
  – Male, <1 year of age, ↑ ESR >4 weeks, fever >2 weeks, fever >48 hours after IVIG treatment
• Mortality of 0.08–0.17% is due to cardiac disease.

REFERENCES

ADDITIONAL READING

CODES

ICD10
M30.3 Mucocutaneous lymph node syndrome [Kawasaki]

CLINICAL PEARLS

- The diagnosis of KS rests on a constellation of clinical features.
- Once KS is suspected, all patients need an inpatient cardiac evaluation, including ECG and echocardiogram.
- Expert recommendation for optimal therapy is IVIG 2 g/kg IV over 10 hours, with high-dose aspirin 80 to 100 mg/kg/day in 4 doses.
KERATOACANTHOMA
Patrick M. Zito, DO • Kenneth Beer, MD

BASICS

DESCRIPTION

- Most common is a solitary, rapidly proliferating, dome-shaped, erythematous or flesh-colored papule or nodule with a central keratinous plug, typically reaching 1 to 2 cm in diameter.
- Clinically and microscopically resemble squamous cell carcinoma (SCC)
- Other presentations include grouped, multiple, keratoacanthoma (KA) centrifugum marginatum, intraoral, subungual, regressing, nonregressing, generally eruptive (1).
- Majority are benign and resolve spontaneously, but lesions do have the potential for invasion and metastasis, therefore require treatment.
- Three clinical stages of KAs (1):
  - Proliferative: rapid growth of the lesion over weeks to several months
  - Maturation/stabilization: Lesion stabilizes and growth subsides.
  - Involution: spontaneous resolution of the lesion, leaving a hypopigmented, depressed scar; most but not all lesions will enter this stage.
- System(s) affected: integumentary

EPIDEMIOLOGY

- Greatest incidence age >50 years but may occur at any age
- Presentation increased during summer and early fall seasons
- Most frequently on sun-exposed, hair-bearing skin but may occur anywhere
- Predominant sex: male > female (2:1)
- Most commonly in fair-skinned individuals; highest rates in Fitzpatrick I to III
- 104 cases per 100,000 individuals

ETIOLOGY AND PATHOPHYSIOLOGY

- Derived from an abnormality causing hyperkeratosis within the follicular infundibulum
- Squamous epithelial cells proliferate to extend upward around the keratin plug and proceed downward into the dermis; followed by invasion of elastic and collagen fibers
- Cellular mechanism responsible for the hyperkeratosis is currently unknown; role of human papillomavirus (HPV) has been discussed but has no established causality (2).
- Regression may be due to immune cytotoxicity or terminal differentiation of keratinocytes.
- Multiple etiologies have been suggested:
  - UV radiation
  - May be provoked by surgery, cryotherapy, chemical peels, or laser therapy
  - Viral infections: HPV or Merkel cell polyomavirus
  - Genetic predisposition: Muir-Torre syndrome, xeroderma pigmentosum, Ferguson-Smith syndrome
  - Immunosuppression
  - BRAF inhibitors (1)
  - Chemical carcinogen exposure

Genetics
Mutation of p53 or H-ras
Ferguson-Smith (AD)
Witten-Zak (AD)
Muir-Torre (AD)
Xeroderma pigmentosum (AR)
Grzybowski (periodic)
Incontinentia pigmenti (XLD)

**RISK FACTORS**
- UV exposure/damage: outdoor and/or indoor tanning
- Fitzpatrick skin types I to III
- Trauma (typically appears within 1 month of injury): laser resurfacing, surgery, cryotherapy, tattoos
- Chemical carcinogens: tar, pitch, and smoking
- Immunocompromised state
- Discoid lupus erythematosus
- HPV infection

**GENERAL PREVENTION**
Sun protection

**COMMONLY ASSOCIATED CONDITIONS**
- Frequently, the patient has concurrent sun-damaged skin: solar elastosis, solar lentigines, actinic keratosis, nonmelanoma skin cancers (basal cell carcinoma, SCC).
- In Muir-Torre syndrome, KAs are found with coexisting sebaceous neoplasms and malignancy of the GI and GU tracts; may have sebaceous differentiation known as a seboacanthoma

**DIAGNOSIS**

**HISTORY**
- Lesion begins as a small, solitary, pink macule that undergoes a rapid growth phase; classically reaching a diameter of 1 to 2 cm; size may vary.
- Once the proliferative stage has subsided, lesion size remains stable.
- May decrease in size, indicating regression
- Asymptomatic, occasionally tender
- If multiple lesions present, important to elicit a family history and recent therapies or treatments
- If sebaceous neoplasms present, must review history for signs/symptoms of GI or GU malignancies

**PHYSICAL EXAM**
- Firm, solitary, erythematous or flesh-colored, dome-shaped papule or nodule with a central keratin plug, giving a crateriform appearance
- Surrounding skin and borders of lesion may show telangiectasia, atrophy, or dyspigmentation.
- Usually solitary; multiple lesions can occur.
- Most commonly seen on sun-exposed areas: face, neck, scalp, dorsum of upper extremities, and posterior legs
• May also be seen on areas without sun exposure: buttocks, anus, subungual, mucosal surfaces
• Subungual KAs are very painful and seen on the first 3 digits of the hands.
• Examine for regional lymphadenopathy due to chance of lesion invasion and metastasis.
• Dermoscopy (3)
  – Central keratin highest sensitivity to distinguish from SCC (4)
  – White circles, blood spots; white circles highest specificity (4)
  – Cannot reliably distinguish between KA and SCC

DIFFERENTIAL DIAGNOSIS
• SCC
• Nodular or ulcerative basal cell carcinoma
• Cutaneous horn
• Hypertrophic actinic keratosis
• Amelanotic melanoma
• Merkel cell carcinoma
• Metastasis to the skin
• Molluscum contagiosum
• Prurigo nodularis
• Verruca vulgaris
• Verrucous carcinoma
• Sebaceous adenoma
• Hypertrophic lichen planus
• Hypertrophic lupus erythematosus
• Deep fungal infection
• Atypical mycobacterial infection
• Nodular Kaposi sarcoma

DIAGNOSTIC TESTS & INTERPRETATION
• Excisional biopsy, including the center of the lesion as well as the margin, is the best diagnostic test (2)[C].
• A shave biopsy may be insufficiently deep to distinguish KA from an SCC.
• If unable to perform an excisional biopsy, a deep shave (saucerization) of the entire lesion, extending into the subcutaneous fat, can be done.
• Punch biopsies should be avoided because they give an insufficient amount of tissue to represent the entire lesion.

Initial Tests (lab, imaging)
• Subungual KA: radiograph of the digit to monitor for osteolysis (cup-shaped radiolucent defect)
• Aggressive tumors may need CT with contrast for evaluation of lymph nodes and MRI if there is concern of perineural invasion.
• Most lesions do not need any form of imaging.

Test Interpretation
• Pathology of biopsy: a well-demarcated central core of keratin surrounded by well-differentiated, mildly pleomorphic, atypical squamous epithelial cells with a characteristic glassy eosinophilic cytoplasm
• Histopathology: keratin-filled crater encompassed with epithelial lips
- May see elastic and collagen fibers invading into the squamous epithelium
- Histologic differentiation of a KA from an SCC may be difficult and unreliable, although immunochemical staining for cellular protein Ki-67 may help do this (4).
- KAs have a greater tendency than SCC to display fibrosis and intraepidermal abscesses of neutrophils and eosinophils.
- Regressing KA shows flattening and fibrosis at base of lesion.

**TREATMENT**

- Treatment of choice is an excisional procedure plus electrodessication and curettage (ED&C); however, there are many treatment options available (2)[C].
- Aggressive tumors (>2 cm) or lesions in cosmetically sensitive areas (face, digits, genitalia) that require tissue sparing, consider Mohs micrographic surgery
  - Mohs is the treatment of choice in cases with perineural or perivascular invasion.
- Small lesions (<2 cm) of the extremities may undergo ED&C.
- Immunocompromised patients should receive immediate surgical treatment.

**MEDICATION**

- Nonsurgical management is a viable and relatively cost-effective option in these select cases not amenable to surgery due to lesion number, size, or location; also for patients with multiple comorbidities who are unwilling or unable to withstand surgery
- Evidence for the following treatments based on case reports and retrospective reviews:
  - Intralesional methotrexate 12.5 to 25.0 mg in 0.5 mL normal saline every 2 to 3 weeks for 1 to 4 treatment sessions (5)[B]
    - Monitor for pancytopenia with complete blood count (5)[C].
  - 5% imiquimod cream 3 times per week for 11 to 13 weeks (5)[B]
  - Topical 5% 5-fluorouracil cream daily, 61–92% cure rate (5)[B]
  - Intralesional 5-fluorouracil of 50 mg/mL on a weekly basis for 3 to 8 treatment sessions—98% cure rate (5)[B]
  - Intralesional IFN α-2a or α-2b (83%, 100% cure rate, respectively) (5)[B]
  - Intralesional bleomycin—100% cure rate (5)[B]
  - Isotretinoin oral 0.5 to 1.0 mg/kg/day

**ISSUES FOR REFERRAL**
Dermatology referral if lesions are >2 cm, numerous, mucosal, or subungual

**ADDITIONAL THERAPIES**

- Photodynamic therapy with methyl aminolevulinic acid and red light, successful case reports (1)[B] but also reported aggravation following treatment
- Cryotherapy (1)
- Argon or YAG lasers
- Radiotherapy, primary or adjuvant: KAs may regress with low doses of radiation but may require doses up to 25 to 50 Gy in low-dose (5 to 10 Gy) fractions for possible SCC (1)[B].
- Erlotinib (EGFR inhibitor) 150 mg daily for 21 days, single case report (1)[B]

**SURGERY/OTHER PROCEDURES**
Excisional and office-based procedures as discussed above
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

After the surgical site has healed or lesion has resolved, patient should be seen every 6 months due to increased risk of developing new lesions or skin cancers, annually at minimum (3)[C].

Patient Monitoring
- Skin self-exams should be routinely performed with detailed instructions (see “Additional Reading”).
- If multiple KAs are present in patient or family members, evaluate for Muir-Torre syndrome and obtain a colonoscopy beginning at age 25 years as well as testing for genitourinary cancer (3)[C].

PATIENT EDUCATION
- Sun protection measures: sun block with SPF >30, wide-brimmed hats, long sleeves, dark clothing, avoiding indoor tanning
- Arc welding may produce harmful UV radiation and skin should not be exposed.
- Tar, pitch, and smoking should be avoided.

PROGNOSIS
- Atrophic scarring and hypopigmentation can occur with self-resolution but may be significantly reduced by intervention.
- 52 of 445 cases (12%) spontaneously regressed without treatment and none of these recurred (2).
- 393 (88%) regressed following medical or excisional treatment (2).
- 445 cases reported with no metastases or deaths attributable to the KA (2)
- 4–8% recurrence
- Mucosal and subungual lesions do not regress; must undergo treatment

SKIN CANCER

Types of Skin Cancer

The Skin Cancer Foundation: [http://www.skincancer.org/](http://www.skincancer.org/)

SEE ALSO

Squamous Cell Carcinoma, Cutaneous

CODES

ICD10

- D23.9 Other benign neoplasm of skin, unspecified
- D48.5 Neoplasm of uncertain behavior of skin
- L85.8 Other specified epidermal thickening

CLINICAL PEARLS

- Suspect KA with a solitary, dome-shaped, erythematous or flesh-colored papule or nodule with a central keratinous plug.
- If KA is in the differential diagnosis, elicit time frame of onset during patient encounter; rapid onset supports diagnosis.
- Due to the broad differential diagnosis of a suspected KA and unreliable clinical differentiation between these, strongly consider surgical excision as first-line diagnostic test and therapy.
- Medical and radiation therapies are reasonable and effective options available for patients who are not surgical candidates or for lesions that are not amenable for surgery.
KERATOSIS, ACTINIC
Zoltan Trizna, MD, PhD

BASICS
DESCRIPTION
- Common, usually multiple, premalignant lesions of sun-exposed areas of the skin. Many resolve spontaneously, and a small proportion progresses to squamous cell carcinoma (SCC).
- Common consequence of excessive cumulative ultraviolet (UV) light exposure
- Synonym(s): solar keratosis

Geriatric Considerations
Frequent problem

Pediatric Considerations
Rare (if child, look for freckling and other stigmata of xeroderma pigmentosum)

EPIDEMIOLOGY
Incidence
- Rates vary with age group and exposure to sun.
- Predominant age: ≥40 years; progressively increases with age
- Predominant sex: male > female
- Common in those with blonde and red hair; rare in darker skin types

Prevalence
- Age-adjusted prevalence rate for actinic keratoses (AKs) in U.S. Caucasians is 6.5%.
- For 65- to 74-year-old males with high sun exposure: ~55%; low sun exposure: ~18%

ETIOLOGY AND PATHOPHYSIOLOGY
- The epidermal lesions are characterized by atypical keratinocytes at the basal layer with occasional extension upward. Mitoses are present. The histopathologic features resemble those of SCC in situ or SCC, and the distinction depends on the extent of epidermal involvement.
- Cumulative UV exposure

Genetics
The p53 chromosomal mutation has been shown consistently in both AKs and SCCs. Many new genes have been shown recently to have similar expression profiles in AKs and SCCs.

RISK FACTORS
- Exposure to UV light (especially long-term and/or repeated exposure due to outdoor occupation or recreational activities, indoor or outdoor tanning)
- Skin type: burns easily, does not tan
- Immunosuppression, especially organ transplantation

GENERAL PREVENTION
Sun avoidance and protective techniques are helpful.

COMMONLY ASSOCIATED CONDITIONS
- SCC
- Other features of chronic solar damage: lentigines, elastosis, and telangiectasias

**DIAGNOSIS**

**HISTORY**
- The lesions are frequently asymptomatic; symptoms may include pruritus, burning, and mild hyperesthesia.
- Lesions may enlarge, thicken, or become more scaly. They also may regress or remain unchanged.
- Most lesions occur on the sun-exposed areas (head and neck, hands, forearms).

**PHYSICAL EXAM**
- Usually small (<1 cm), often multiple red, pink, or brown macules, papules, or plaques that are rough to palpation
- Yellow or brown adherent scale is often present on top of the lesion.
- Several clinical variants exist.
  - Atrophic: dry, scaly macules with indistinct borders and an erythematous base
  - Hypertrophic: Overlying hyperkeratosis (in an extreme form, cutaneous horn) may be impossible to differentiate from SCC clinically.
  - Pigmented: smooth tan/brown plaque, spreading centrifugally
  - Bowenoid: red scaly plaques with distinct borders
  - Actinic cheilitis: inflammatory lesion involving usually the lower lip

**DIFFERENTIAL DIAGNOSIS**
- SCC (hypertrophic type)
- Keratoacanthoma
- Bowen disease
- Basal cell carcinoma
- Verruca vulgaris
- Less likely: verrucous nevi, warty dyskeratoma, lichenoid keratoses, seborrheic keratoses, porokeratoses, seborrheic dermatitis or psoriasis (near hairline), lentigo maligna, solar lentigo, discoid lupus erythematosus

**DIAGNOSTIC TESTS & INTERPRETATION**

**Diagnostic Procedures/Other**
- The diagnosis is usually made clinically, except where there is a suspicion of carcinoma.
- Skin biopsy is especially recommended if large, ulcerated, indurated, or bleeding, or if the lesions are nonresponsive to treatment.

**Test Interpretation**
- Dysplastic keratinocytes in lower levels of epidermis with a dermal lymphocytic infiltrate
- Neoplastic cells, mostly found in the lower epidermal layers, are cytologically identical to those of SCCs.
- If neoplastic cells extend throughout entire epidermis or into the dermis, the lesions will qualify as an SCC in situ or invasive SCC, respectively.
- Malignant cells are sparse except of the Bowenoid variety.
Hypertrophic, atrophic, Bowenoid, acantholytic, and pigmented varieties show the corresponding epidermal findings.

**TREATMENT**

- First-line treatment is cryotherapy (technically, this is considered surgery, especially by insurance companies) (1,2).[A]. Medical therapy is usually reserved for extensive AKs (“field therapy”).
- Cryotherapy combined with a topical approach resulted in significantly higher complete clearance rates than monotherapy (3).[A].

**GENERAL MEASURES**

- Sun-protective techniques
- Sunscreens and physical sun protection recommended

**MEDICATION**

**First Line**

- Topical treatments target both visible and subclinical lesions.
- With the exception of generic 5-fluorouracil, medication cost is high ($600 to $1,200 per course).
- Topical fluorouracil (Efudex, Carac, Fluoroplex cream, Fluoroplex solution)
  - Every day—BID for 3 to 6 weeks, depending on the brand, concentration, and formulation
  - Can be very irritating
  - May be most effective of the topical treatments listed in this section (3).[A]
- Topical imiquimod (Aldara) 5% cream
  - Apply 2 days per week at HS for up to 16 weeks to an area not larger than the forehead or one cheek.
  - Can be irritating
- Topical imiquimod (Zyclara) 3.75% cream
  - Apply once a day for 2 weeks, followed by no treatment for the next 2 weeks, and then apply once a day for another 2 weeks.
  - Can be irritating
- Topical ingenol mebutate (Picato) 0.015% and 0.05% gel
  - Apply to the face and scalp once a day for 3 consecutive days.
  - Apply to the trunk and extremities once a day for 2 consecutive days.
    - It should only be used on one contiguous skin area of not >25 cm².
    - Cases of severe allergic reactions (including anaphylaxis) and herpes zoster reactivation unrelated to application errors have been reported.
- Diclofenac (Solaraze) 3% gel
  - Apply BID for 60 to 90 days.

**Second Line**

- Topical tretinoin (Retin-A) or tazarotene (Tazorac): may be used to enhance the efficacy of topical fluorouracil
- Systemic retinoids: used infrequently

**ADDITIONAL THERAPIES**
Close monitoring with no treatment is an appropriate option for mild lesions.

**SURGERY/OTHER PROCEDURES**
- Cryosurgery (“freezing,” liquid nitrogen)
  - Most common method for treating AK
  - Cure rate: 75–98.8%
  - May cause atrophy and hypopigmentation
  - May be superior to photodynamic therapy for thicker lesions
- Photodynamic therapy with a photosensitizer (e.g., aminolevulinic acid) and “blue light”
  - May clear >90% of AKs
  - Less scarring than cryotherapy
  - May be superior to cryotherapy, especially in the case of more extensive skin involvement
- Curettage and electrocautery (electrodesication and curettage [ED&C]; “scraping and burning”)
- Medium-depth peels, especially for the treatment of extensive areas
- CO₂ laser therapy
- Dermabrasion
- Surgical excision (excisional biopsy)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Depends on associated malignancy and frequency with which new AKs appear

**PATIENT EDUCATION**
- Teach sun-protective techniques.
  - Limit outdoor activities between 10 am and 4 pm.
  - Wear protective clothing and wide-brimmed hat.
  - Proper use (including reapplication) of sunscreens with SPF >30, preferably a preparation with broad-spectrum (UV-A and UV-B) protection
- Teach self-examination of skin (melanoma, squamous cell, basal cell).
- Patient education materials

**PROGNOSIS**
Very good. A significant proportion of the lesions may resolve spontaneously (4), with regression rates of 20–30% per lesion per year.

**COMPLICATIONS**
- AKs are premalignant lesions that may progress to SCCs. The rate of malignant transformation is unclear; the reported percentages vary but range from 0.1% to a few percent per year per lesion.
- Patients with AKs are at increased risk for other cutaneous malignancies.
- Approximately 60% of SCCs arise from an AK precursor.
REFERENCES

ADDITIONAL READING

CODES

ICD10
L57.0 Actinic keratosis

CLINICAL PEARLS

- AKs are premalignant lesions, although most will not progress to squamous cell cancer and many will regress with time.
- Often more easily felt than seen
- Therapy-resistant lesions should be biopsied, especially on the face.
KERATOSIS, SEBORRHEIC
Michael T. Partin, MD • Karl T. Clebak, MD, FAAFP

BASICS

DESCRIPTION
- Common benign tumor of the epidermis
- Formed from proliferation of keratinocytes
- Frequently appears in multiples on the head, neck, and trunk of older individuals but may occur on any hair-bearing area of the body. Lesions spare the palms and soles.
- Typically presents as multiple, well circumscribed, yellow to brown raised lesions that feel greasy, velvety, or warty usually described as having a “stuck-on” appearance
- Clinical variants include the following:
  - Common seborrheic keratosis
  - Dermatosis papulosa nigra
  - Stucco keratosis
  - Flat seborrheic keratosis
  - Pedunculated seborrheic keratosis
- System(s) affected: integumentary
- Synonym(s): SK, verruca seborrhoica; seborrheic wart; senile wart; basal cell papilloma; verruca senilis; basal cell acanthoma; benign acanthokeratoma; barnacles of aging

EPIDEMIOLOGY

Incidence
- Predominant age:
  - rarely seen before 30 years
- Predominant sex: slightly more common and more extensive involvement in males
- Most common among Caucasians, except for the dermatosis papulosa nigra variant, which usually presents in darker skinned individuals

Prevalence
- 69–100% in patients >50 years of age \(^1\)
- The prevalence rate increases with advancing age.

ETIOLOGY AND PATHOPHYSIOLOGY

- Etiology remains largely unclear with ultraviolet (UV) light and genetics thought to be involved.
- The role of human papillomavirus is uncertain.

Genetics
An autosomal dominant inheritance pattern is suggested.

RISK FACTORS
- Advanced age
- Exposure to UV light and genetic predisposition are possible factors \(^1\).

GENERAL PREVENTION
Sun protection methods may help prevent seborrheic keratoses from developing.

COMMONLY ASSOCIATED CONDITIONS
- Sign of Leser-Trélat: A paraneoplastic syndrome characterized by a rapid outbreak of multiple seborrheic keratoses often associated with an internal malignancy, most commonly adenocarcinoma of the stomach (2). Seborrheic keratosis may resolve with treatment of the malignancy and reappear with neoplasm recurrence (1).
- Documentation of other cutaneous lesions, such as basal cell carcinoma, malignant melanoma, Bowen disease, or squamous cell carcinoma, growing adjacent to or within a seborrheic keratosis, has been reported. The exact relationship between lesions is unclear.

DIAGNOSIS

HISTORY
Generally asymptomatic, but trauma or irritation of the lesion may result in pruritus, erythema, bleeding, pain, and/or crusting.

PHYSICAL EXAM
- Typically begin as oval- or round-shaped, flat, dull, sharply demarcated patches
- As they mature, may develop into thicker, elevated, uneven, verrucous-like papules, plaques, or peduncles with a waxy or velvety surface, and appear “stuck on” to the skin (1)
- Commonly appear on sun-exposed areas of the body, predominately the head, neck, or trunk but may appear on any hair-bearing skin
- Surface tends to crumble when scratched
- Vary in color (black, brown, tan, gray to white, or skin-colored) as well as size ranging from several millimeters to several centimeters, but the average diameter is 0.5 to 1.0 cm (1)
- Usually occur as multiples; patients having >100 is not uncommon
- If irritated, may be bleeding, inflamed, painful, pruritic, or crusted
- Common clinical variants include (3):
  - Common seborrheic keratoses: on hair-bearing skin, usually on the face, neck, and trunk; verrucous-like, waxy, or velvety lesions that appear “stuck on” to the skin
  - Dermatosis papulosa nigra: Small black papules that usually appear on the face, neck, chest, and upper back; symmetric distribution most common in darker skinned individuals, more common in females; most have a positive family history.
  - Stucco keratoses: small gray-white, rough, verrucous papules; usually occur in large numbers on the lower extremities or forearms; more common in men
  - Flat seborrheic keratoses: oval-shaped, tan to brown patches or macules on face, chest, and upper extremities; increases with age
  - Pedunculated seborrheic keratoses: Hyperpigmented peduncles appear on areas of friction (neck, axilla).

DIFFERENTIAL DIAGNOSIS
Consider the following diagnoses if the seborrheic keratosis is:
- Pigmented
  - Malignant melanoma
  - Melanocytic nevus
  - Angiokeratoma
- Pigmented basal cell carcinoma
- Lightly pigmented
  - Basal cell carcinoma
  - Bowen disease
  - Condyloma acuminatum
  - Fibroma
  - Verruca vulgaris
  - Eccrine poroma
  - Invasive squamous cell carcinoma
  - Acrochordon
  - Acrokeratosis verruciformis of Hopf
  - Follicular infundibulum tumor
- Flat
  - Solar lentigo
  - Verrucae planae juveniles
- Hyperkeratotic
  - Actinic keratosis

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)
Not needed unless internal malignancy is suspected

### Diagnostic Procedures/Other
- Diagnosis is made clinically.
- Dermoscopy
  - If uncertain, can aid in diagnosis
  - Common findings are comedo-like openings, fissures, ridges, sharply demarcated borders, milia-like cysts, pseudofollicular openings, hairpin vessels, and horn pseudocysts (4,5).
- Biopsy and histologic exam should be performed if the seborrheic keratosis:
  - Is atypical
  - Has inflammation
  - Recently changed in appearance
  - Diagnosis remains unclear.

### Test Interpretation
- Histologic findings include the following:
  - Acanthosis and papillomatosis due to basaloid cell proliferation
  - “Squamous eddies” or squamous epithelial cell clusters
  - Hyperpigmentation
  - Hyperkeratosis
  - Horn cysts
  - Pseudocysts
- Several histologic variants exist.

## TREATMENT
- Treatment is not usually necessary due to the benign nature of the lesions.
Removal of seborrheic keratoses may be indicated if
- Symptomatic (e.g., easily irritated, gets caught on clothing or jewelry)
- Aesthetically displeasing or undesirable (common)
- There is a question of malignancy

MEDICATION
- Current topical treatments of seborrheic keratoses are less effective than a surgical approach.
- 40% hydrogen peroxide topical solution approved by FDA with a preliminary study showing limited effectiveness compared to standard procedures of removal, and often requires 2 or more office visits (6). Application is time-consuming. There is no convincing evidence that this topical approach is better cosmetically than older treatment methods.

ISSUES FOR REFERRAL
- New seborrheic keratoses appear abruptly.
- A seborrheic keratosis becomes inflamed or changes in appearance

SURGERY/OTHER PROCEDURES
- A surgical approach to treatment is preferred.
- Choice depends on physician preference and availability of the treatment.
- The following procedures are used:
  - Cryotherapy (liquid nitrogen)
    - Spray flat lesions for 5 to 10 seconds; may require more time or additional treatments if the seborrheic keratosis is thicker
    - Possible complications include scarring, hypopigmentation, recurrence.
  - Curettage
    - Requires local anesthesia
    - Metal hand tool with small scoop at the tip (curette) used to scrape off the lesion
  - Electrodesiccation
    - Requires local anesthesia
    - Requires tool with needle-like metal tip that uses electric current to destroy affected tissue
  - Shave excision
    - Requires local anesthesia
    - Requires scalpel to remove lesion
  - Laser
    - Requires local anesthesia
    - Uses intense beam of light that burns and vaporizes the lesion
  - Chemical peel
    - Involves application of chemical solution (e.g., trichloroacetic acid) to remove top layer of skin
- No statistically significant differences were found in patient’s ratings of cosmetic appearance between cryotherapy and curettage. The majority of patients preferred cryotherapy over curettage due to decreased postoperative wound care, despite the increased discomfort experienced and increased frequency of seborrheic keratosis remaining after cryotherapy (7).
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
After initial diagnosis, follow-up is not usually required unless:

- Inflammation or irritation develops
- There is a change in appearance
- New seborrheic keratoses suddenly appear

PATIENT EDUCATION

- Sun-protective methods may help reduce seborrheic keratosis development.
- Patient education materials
  - [www.cdc.gov/cancer/skin/basic_info/prevention.htm](http://www.cdc.gov/cancer/skin/basic_info/prevention.htm)

PROGNOSIS

- Seborrheic keratoses generally do not become malignant.
- Sign of Leser-Trélat usually represents a poor prognosis.

COMPLICATIONS

- Irritation and inflammation due to mechanical irritation (i.e., from clothing, jewelry)
- Possible complications of surgical treatment include hypopigmentation, hyperpigmentation, scarring, incomplete removal, and recurrence.
- Misdiagnosis (rare)

REFERENCES

ADDITIONAL READING

- Garcia MS, Azari R, Eisen DB. Treatment of dermatosis papulosa nigra in 10 patients: a

**CODES**

**ICD10**

- L82.1 Other seborrheic keratosis
- L82.0 Inflamed seborrheic keratosis

**CLINICAL PEARLS**

- Seborrheic keratoses are one of the most common benign tumors of the epidermis.
- Prevalence increases with age.
- Underlying internal malignancy should be considered if large numbers of seborrheic keratoses appear suddenly.
KNEE PAIN
J. Herbert Stevenson, MD • James McKee, DO, MS

BASICS

DESCRIPTION
A common outpatient complaint with a broad differential
- Knee pain may be acute, chronic, or an acute exacerbation of a chronic condition.
- Trauma, overuse, and degenerative change are frequent causes.
- A detailed history, including patient’s age, pain onset and location, mechanism of injury, and associated symptoms can help narrow the differential diagnosis.
- A thorough and focused examination of the knee (as well as the back, hips, and ankles) helps to establish the correct diagnosis and appropriate treatment.

EPIDEMIOLOGY

Incidence
- Knee complaints account for 12.5 million primary care visits annually.
- The incidence of knee osteoarthritis (OA) is 240 cases per 100,000 person-years.

Prevalence
- The knee is a common site of lower extremity injury.
  - Patellar tendinopathy and patellofemoral syndrome are the most common causes of knee pain in runners.
- OA of the hip/knee is 11th cause of global disability and 38th most common cause of disability-adjusted life years (DALYs).

ETIOLOGY AND PATHOPHYSIOLOGY

- Trauma (ligament or meniscal injury, fracture, dislocation)
- Overuse (tendinopathy, patellofemoral syndrome, bursitis, apophysitis)
- Age (arthritis, degenerative conditions in older patients; apophysitis in younger patients)
- Rheumatologic (rheumatoid arthritis [RA], systemic lupus erythematosus [SLE])
- Crystal arthropathies (gout, pseudogout)
- Infectious (bacterial, postviral, Lyme disease)
- Referred pain (hip, back)
- Vascular: popliteal artery aneurysm, deep vein thrombosis
- Others: tumor, cyst, plica

RISK FACTORS

- Obesity
- Malalignment
- Poor flexibility, muscle imbalance, or weakness
- Rapid increases in training frequency and intensity
- Improper footwear, training surfaces, technique
- Activities that involve cutting, jumping, pivoting, deceleration, kneeling
- Previous injuries
GENERAL PREVENTION

- Maintain normal body mass index.
- Proper exercise technique, volume, and equipment; avoid overtraining.
- Correct postural strength and flexibility imbalances.

COMMONLY ASSOCIATED CONDITIONS

- Fracture, contusion
- Effusion, hemarthrosis
- Patellar dislocation/subluxation
- Meniscal or ligamentous injury
- Tendinopathy, bursitis
- Osteochondral injury
- OA, septic arthritis
- Muscle strain

DIAGNOSIS

HISTORY

- Pain location, quality, and mechanism of injury guide diagnostic reasoning (also see “Differential Diagnosis”):
  - Diffuse pain: OA, patellofemoral pain syndrome, chondromalacia
  - Pain ascending/descending stairs: meniscal injury, patellofemoral pain syndrome
  - Pain with prolonged sitting, standing from sitting: patellofemoral pain syndrome
  - Mechanical symptoms (locking): meniscal injury
- Mechanism of injury:
  - Hyperextension, deceleration, cutting: anterior cruciate ligament (ACL) injury
  - Hyperflexion, fall on flexed knee, “dashboard injury”: posterior cruciate ligament (PCL) injury
  - Lateral force (valgus load): medial collateral injury
  - Twisting on planted foot: meniscal injury
- Effusion:
  - Rapid onset (2 hours): ACL tear, patellar subluxation, tibial plateau fracture. Hemarthrosis is common.
  - Slower onset (24 to 36 hours), smaller: meniscal injury, ligament sprain, arthritis
  - Swelling behind the knee: popliteal (Baker) cyst

PHYSICAL EXAM

- Observe gait (antalgia); patellar tracking
- Inspect for malalignment, atrophy, swelling, ecchymosis, or erythema.
- Palpate for effusion, warmth, and tenderness.
- Evaluate active and passive range of motion (ROM) and flexibility of quadriceps and hamstrings.
- Evaluate strength and muscle tone.
- Note joint instability, locking, and catching.
- Evaluate hip ROM, strength, and stability.
- Special tests:
– Patellar apprehension test: patellar instability; patellar grind test: patellofemoral pain or OA
  (1)
– Lachman test (more sensitive and specific), pivot shift, anterior drawer: ACL integrity
– Posterior drawer, posterior sag sign: PCL integrity
– Valgus/varus stress test: medial/lateral collateral ligament (MCL/LCL) integrity
– McMurray test, Apley grind test, Thessaly test: meniscal injury
– Ober test: iliotibial band (ITB) tightness
– Dial test: positive with posterolateral corner laxity
– Patellar tilt test and squatting may help suggest patellofemoral pain syndrome.
– Patella facet tenderness suggests OA or patellofemoral pain syndrome (1).

DIFFERENTIAL DIAGNOSIS

- Acute onset: fracture, contusion, cruciate or collateral ligament tear, meniscal tear, patellar dislocation/subluxation; if systemic symptoms: septic arthritis, gout, pseudogout, Lyme disease, osteomyelitis
- Insidious onset: patellofemoral pain syndrome/chondromalacia, ITB syndrome, OA, RA, bursitis, tumor, tendinopathy, loose body, bipartite patella, degenerative meniscal tear
- Anterior pain: patellofemoral pain syndrome, patellar injury, patellar tendinopathy, pre- or suprapatellar bursitis, tibial apophysitis, fat pad impingement, quadriceps tendinopathy, OA (1)
- Posterior pain: PCL injury, posterior horn meniscal injury, popliteal cyst or aneurysm, hamstring or gastrocnemius injury, deep venous thrombosis (DVT)
- Medial pain: MCL injury, medial meniscal injury, pes anserine bursitis, medial plica syndrome, OA
- Lateral pain: LCL injury, lateral meniscal injury, ITB syndrome, OA

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Suspected septic joint, gout, pseudogout:
  – Arthrocentesis with cell count, Gram stain, culture, protein/glucose, synovial fluid analysis
- Suspected RA:
  – CBC, erythrocyte sedimentation rate (ESR), rheumatoid factor
- Consider Lyme titer.
- Radiographs to rule out fracture in patients with acute knee trauma (Ottawa Rules):
  – Age >55 years or
  – Tenderness at the patella or fibular head or
  – Inability to bear weight four steps or
  – Inability to flex knee to 90 degrees
- Radiographs help diagnose OA, osteochondral lesions, patellofemoral pain syndrome:
  – Weight-bearing, upright anteroposterior, lateral, merchant/sunrise, notch/tunnel views

Follow-Up Tests & Special Considerations
- MRI is “gold standard” for soft tissue imaging.
- Ultrasound may help diagnose tendinopathy (2)[B].
- CT can further elucidate fracture.

Diagnostic Procedures/Other
Arthroscopy may be beneficial in the diagnosis of certain conditions, including meniscus and ligament injuries.

**Geriatric Considerations**
OA, degenerative meniscal tears, and gout are more common in middle-aged and elderly populations.

**Pediatric Considerations**
- 3 million pediatric sports injuries occur annually.
- Look for physeal/apophyseal and joint surface injuries in skeletally immature:
  - Acute: patellar subluxation, avulsion fractures, ACL tear
  - Overuse: patellofemoral pain syndrome, apophysitis, osteochondritis dissecans, patellar tendonitis, stress fracture
  - Others: neoplasm, juvenile RA, infection, referred pain from slipped capital femoral epiphysis

**GENERAL MEASURES**
Acute injury: PRICEMM therapy (protection, relative rest, ice, compression, elevation, medications, modalities)

**MEDICATION**

**First Line**
- Oral medications:
  - Acetaminophen: up to 3 g/day; safe and effective in OA
  - Nonsteroidal anti-inflammatory drugs (NSAIDs):
    - Ibuprofen: 200 to 800 mg TID
    - Naproxen: 250 to 500 mg BID:
      - Useful for acute sprains, strains
      - Useful for short-term pain reduction in OA. Long-term use is not recommended due to side effects.
      - Not recommended for fracture, stress fracture, chronic muscle injury; may be associated with delayed healing; low dose and brief course only if necessary
  - Tramadol/opioids: not recommended as first-line treatment; can be used with acute injuries for severe pain
    - Celecoxib: 200 mg QD may be effective in OA with less GI side effects than NSAIDs (3) [A].
- Topical medications:
  - Topical NSAIDs provide pain relief in OA and may be more tolerable than oral medications (4)[A].
  - Topical capsaicin may be an adjuvant for pain management in OA.
- Injections:
  - Intra-articular corticosteroid injection may provide short-term benefit in knee OA stage 2 or 3 (2)[A].
  - Viscosupplementation may reduce pain and improve function in patients with OA (2)[A].
Peak effectiveness is 5 to 13 weeks.
- Equivocal evidence for platelet-rich plasma (PRP) compared to viscosupplementation
- Stem cell therapy with insufficient data

**ISSUES FOR REFERRAL**
- Acute trauma, young athletic patient
- Joint instability
- Lack of improvement with conservative measures
- Salter-Harris physeal fractures (pediatrics)

**ADDITIONAL THERAPIES**
- Physical therapy is recommended as initial treatment for patellofemoral pain (5) and tendinopathies (2)[A].
- Muscle strengthening improves outcome in OA.
- Foot orthoses, taping, acupuncture
- May need bracing for stability (5)[B]

**SURGERY/OTHER PROCEDURES**
- Surgery may be indicated for certain injuries (e.g., ACL tear in competitive athletes or grade IV OA).
- Chronic conditions refractory to conservative therapy may require surgical intervention.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
May reduce pain and improve function in early OA:
- Glucosamine sulfate (500 mg TID)
- Chondroitin (400 mg TID)
- Turmeric or curcumin 1,000 mg/day (6)
- Collagen hydrolysates 10 g daily
- S-adenosyl-L-methionine (SAMe), ginger extract, methylsulfonylmethane: less reliable improvement with inconsistent supporting evidence
- Acupuncture: need to do 4 weeks or 10 sessions

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Activity modification in overuse conditions
- Rehabilitative exercise in OA:
  - Low-impact exercise: walking, swimming, cycling
  - Strength, ROM, and proprioception training

**Patient Monitoring**
- Rehabilitation after initial treatment of acute injury
- In chronic and overuse conditions, assess functional status, rehabilitation adherence, and pain control at follow-up visit.

**DIET**
Weight reduction by 10% improved function by 28%.
PATIENT EDUCATION
- Review activity modifications.
- Encourage active role in the rehabilitation process.
- Review medication risks and benefits.

PROGNOSIS
Varies with diagnosis, injury severity, chronicity of condition, patient motivation to participate in rehabilitation, and whether surgery is required

COMPLICATIONS
- Disability
- Arthritis
- Chronic joint instability
- Deconditioning

REFERENCES

ADDITIONAL READING

Algorithms: Knee Pain; Popliteal Mass

CODES

ICD10
- M25.569 Pain in unspecified knee
- M17.9 Osteoarthritis of knee, unspecified
- M76.50 Patellar tendinitis, unspecified knee

CLINICAL PEARLS
- A careful history (location/quality of pain and mechanism of injury) targets diagnosis for most causes of knee pain.
- Consider ligamentous injury, meniscal tear, and fracture for patients presenting with acute knee pain.
- Consider OA, patellofemoral pain syndrome, tendinopathy, bursitis, and stress fracture in patients presenting with more chronic symptoms.
- Consider physeal, apophyseal, or articular cartilage injury in young patients presenting with knee pain.
- The presence of an effusion in a patient <30 years of age indicates a significant injury.
- Referred pain from the hip (slipped capital femoral epiphysis, Legg-Calvé-Perthes disease) can present as knee pain.
LABYRINTHITIS
John Kerr, DO ● Wayne K. Robbins, DO

BASICS

DESCRIPTION

- The sudden onset of vertigo, accompanied by sensorineural hearing loss and tinnitus, lasting hours to days, and caused by acute inflammation or infection of the labyrinth
- Can be categorized as suppurative or serous/toxic labyrinthitis (1)
- Labyrinthitis is a clinical diagnosis in absence of neurologic deficits.
- Typically presents with a subjective sense of motion or room-spinning vertigo lasting for hours or days and often sudden unilateral sensorineural hearing loss
- Often associated with vestibular hypofunction of the involved ear. Peripheral vertigo improves over time with central compensation. Hearing loss generally improves in the case of serous labyrinthitis but is permanent in the case of suppurative labyrinthitis.
- System(s) affected: nervous, special sensory (auditory and vestibular)

ALERT

- “Vertigo” and “dizziness” are commonly used terms. Clarify symptoms by giving options of alternative descriptions such as light-headedness, disequilibrium, room-spinning vertigo, or imbalance.
- Hearing loss and duration of symptoms can help narrow the differential diagnosis in patients with vertigo.
- Vestibular neuritis/neuronitis occurs due to inflammation of the vestibular nerve causing vertigo lasting hours to days without the auditory symptoms of labyrinthitis (2).
- Benign paroxysmal positional vertigo (BPPV) is the most common cause of vertigo. Unlike labyrinthitis, BPPV is episodic, with severe symptoms lasting <1 minute. BPPV is diagnosed using the Dix-Hallpike maneuver. Unlike labyrinthitis, it is not associated with hearing loss.
- Vestibular migraine is the second most common cause of recurrent vertigo, lasting hours and usually with a history of migraine. Up to 10% of cases can occur without headaches (2).

EPIDEMIOLOGY

- Data is lacking for labyrinthitis alone.
- Most common in 30 to 50 years of age (3)
- 10% of all patients seen for dizziness, if vestibular neuritis is included (4)
- Predominant sex: female = male

Incidence

- Estimated incidence of 3.5 per 100,000 if including vestibular neuritis (3)
- Viral labyrinthitis is the most common etiology.
- Suppurative labyrinthitis secondary to otitis media or meningitis is increasingly rare.

Prevalence

20–30% of adults see a health care provider for vertigo in their lifetimes (3). True labyrinthitis is rare.
ETIOLOGY AND PATHOPHYSIOLOGY

- Acute inflammation and damage to the labyrinth, involving both the vestibular apparatus and cochlea.
- Viral or bacterial toxins may pass into the labyrinth directly from the middle ear to labyrinth via the round or oval window, in the case of serous labyrinthitis.
- Bacterial invasion of the inner ear, either from a middle ear infection or meningitis, occurs in suppurative labyrinthitis (1).
- Infections
  - Common viral: cytomegalovirus, mumps, varicella zoster, rubeola, influenza, parainfluenza, herpes simplex, adenovirus, coxsackievirus, respiratory syncytial virus, HIV
  - Common bacterial: Streptococcus pneumoniae, Haemophilus influenzae, Moraxella catarrhalis, Neisseria meningitidis, Streptococcus spp., Staphylococcus spp., Borrelia burgdorferi
  - Treponemal: Treponema pallidum

Genetics

No known genetic link

RISK FACTORS

- Viral upper respiratory infection
- Otitis media
- Cholesteatoma
- Head trauma
- Meningitis

GENERAL PREVENTION

- Early treatment of acute otitis media to prevent complications
- Scheduled immunizations (to prevent common viral pathogens)
- Prevent maternal transmission of pathogens, including syphilis and HIV.

COMMONLY ASSOCIATED CONDITIONS

- Viral upper respiratory infection
- Otitis media
- Cholesteatoma
- Head injury

DIAGNOSIS

HISTORY

- Vertigo AND sensorineural hearing loss in one ear
- Vertigo is acute in onset and lasts hours to days.
- Nausea and vomiting are common.
- Fullness of affected ear
- Tinnitus of affected ear (roaring, ringing)
- Upper respiratory tract infection symptoms
- Otorrhea or otalgia (not common with viral causes)
- Severe headache, fever, and nuchal rigidity in the setting of meningitis
Recurrent symptoms should raise suspicion for autoimmune causes. Profound imbalance or associated focal neurologic signs are not typical and should prompt imaging.

**PHYSICAL EXAM**
- **Nystagmus**
  - Fast-beating nystagmus toward affected ear during the acute phase
  - Fast-beating nystagmus away from affected ear during the convalescent phase, 48 to 72 hours later
- Symptoms abate with eyes open and visual fixation.
- Otologic exam may be unremarkable in the setting of viral labyrinthitis.
- Serous/purulent effusion may be present in the middle ear.
- Retraction of the tympanic membrane and keratinaceous debris may be present with cholesteatoma.

**DIFFERENTIAL DIAGNOSIS**
- Vestibular neuritis/neuronitis (vertigo without hearing loss)
- BPPV: episodic, vertigo lasting seconds/minutes, worse when lying down or looking up
- Ménière disease: episodic vertigo lasting minutes to hours, associated with the triad of episodic vertigo, tinnitus, and hearing loss
- Vestibular migraine
- Autoimmune inner ear disease
- Postconcussive syndrome
- Acute otitis media
- Otoxicity
- Cardiovascular accident (CVA)/brainstem infarct
- Cerebellopontine-angle tumors (e.g., vestibular schwannoma)
- Less common etiologies: parainfectious encephalomyelitis or cranial polyneuritis, Ramsay Hunt syndrome, HIV infection, syphilis, temporal lobe epilepsy, perilymphatic fistula, superior canal dehiscence, idiopathic sudden single-sided deafness, multiple sclerosis, vasculitis (cerebral or systemic)

**DIAGNOSTIC TESTS & INTERPRETATION**
- Routine lab studies are not helpful in making the diagnosis unless an autoimmune cause is highly suspected.
- Consider culture of otorrhea or middle ear fluid to direct antibiotic choice.
- CT of the temporal bone may be indicated in the setting of complicated otitis media or cholesteatoma.
- Consider lumbar puncture only if meningitis is suspected.
- Consider screening for syphilis or HIV when clinically indicated by risk factors or clinical history.
- Imaging is not required for the diagnosis of acute labyrinthitis.
- With acute sensorineural hearing loss or other associated neurologic symptoms, an MRI of the IACs and/or MRA of the brain and brainstem are recommended.

**Follow-Up Tests & Special Considerations**
Labyrinthitis ossificans is fibrosis of the internal auditory canal following bacterial meningitis and is thought to occur due to a suppurative labyrinthitis. This can occur rapidly, especially after
S. pneumoniae meningitis.

**Diagnostic Procedures/Other**
- Audiogram should be obtained.
- Vestibular tests are not typically indicated in the acute setting. If vertigo and dizziness persist after expected resolution of symptoms, videonystagmography should be used.

**Test Interpretation**
- Audiogram may show varying degrees of both sensorineural hearing loss and discrimination loss.
- Caloric testing may show relative weakness of the horizontal semicircular canal of the affected side. Sensitivity and specificity of this test are variable within literature.

**TREATMENT**
- Symptom management and reassurance in the acute phase
- Vestibular suppressants as needed (see “Medication”) for severe acute attacks of vertigo only. Patients should be advised NOT to use these medications as scheduled medications or for prophylaxis without symptoms because this can delay central compensation (2)[B].
- Sudden single-sided sensorineural hearing loss should be managed with high-dose steroids (oral and/or intratympanic) as soon as possible, ideally within 2 weeks. Steroids have not been found to definitively improve vestibular symptoms (5)[B].
- Vestibular rehabilitation is the mainstay of treatment for persistent vertigo and dizziness and has been shown to be safe and effective management for unilateral peripheral vestibular dysfunction (6)[A].
- Patients should begin exercises as soon as the acute phase resolves and movement is tolerable, generally within 2 to 3 days of onset (4).
- For suppurative labyrinthitis, appropriate antibiotics to eradicate infection. Surgical intervention may also be required with tympanostomy tubes or mastoidectomy, depending on the extent of middle ear involvement.

**GENERAL MEASURES**
Vestibular exercises for prolonged symptoms and unilateral vestibular loss have been shown to alleviate postural control.

**MEDICATION**
Use of the following drugs should be on a PRN basis. Benzodiazepines can also assist with the anxiety associated with vertigo. No patient should take vestibular suppressants as a chronic medication because they can block central compensation.
- **Vestibular suppressants**
  - Lorazepam (Ativan): 0.5 to 2.0 mg SL/PO BID PRN or diazepam (Valium) 2 to 5 mg QID PO PRN
  - Meclizine (Antivert, Bonine, Zentrip [dissolvable]) 12.5 to 25.0 mg PO BID–TID PRN
  - Dimenhydrinate (Dramamine) 25 to 50 mg PO q4–6h PRN
- **Antiemetics**
  - Ondansetron (Zofran) 4 to 8 mg PO TID PRN or granisetron (Kytril) 1 mg PO TID PRN
  - Meclizine (Antivert, Bonine) 12.5 to 25.0 mg PO q4h PRN
– Promethazine (Phenergan) 12.5 to 25.0 mg PO/PR QID PRN or prochlorperazine (Compazine) 25 mg PR BID PRN
– Metoclopramide (Reglan) 10 mg PO TID PRN

**Antivirals**
– Acyclovir 800 mg PO 5 times per day for 7 days can be used in cases associated with herpes.

**Steroids**
– Prednisone 1 mg/kg/day up to maximum 60 mg daily for 1 week, followed by 1 week taper
– Methylprednisolone initially 100 mg PO daily and then tapered to 10 mg PO daily over 3 weeks
– Dexamethasone 0.4 to 0.8 mL of 24 mg/mL strength given via transtympanic injection for three to four sessions; can be used for salvage therapy
– Given early in the setting of bacterial meningitis, may decrease the otologic sequelae, specifically labyrinthitis ossificans
– Used in treatment of labyrinthitis for associated sudden sensorineural hearing loss, ideally within the first 2 weeks

**Geriatric Considerations**
– Elderly are less likely to compensate fully and may report symptoms of disequilibrium lasting weeks to months after resolution of the acute vertigo.
– Avoid excessive use of scopolamine, meclizine, and other vestibular suppressants following the initial event because this will delay central compensation.
– Benzodiazepines are the preferred vestibular suppressant treatment but do increase the risk of falls in older persons.

**Pregnancy Considerations**
Dimenhydrinate, diphenhydramine, ondansetron, granisetron, and metoclopramide are pregnancy Category B.

**First Line**
– Benzodiazepines, which are better vestibular suppressants, are preferred over antihistamine/anticholinergics such as meclizine. Sublingual benzodiazepines are very effective for vertigo and should be considered first-line therapy.
– Urgent steroid treatment in acute setting

**ISSUES FOR REFERRAL**
– Consider neurology referral for suspected central causes of vertigo or dizziness.
– Consider otolaryngology/neurotology referral for progressive hearing loss and vertigo, or in cases of suppurative labyrinthitis requiring surgical intervention.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
– Patients with systemic infection, young age, or intractable vertigo with nausea and vomiting may need to be hospitalized for intravenous fluids and medications.
– Usually outpatient management

**ONGOING CARE**
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Follow hearing loss weekly with audiograms until hearing stabilizes. Acute vertiginous symptoms may last up to 6 weeks. Residual symptoms have been documented to last months or years.

Diet
Avoid alcohol because this may exacerbate symptoms.

Patient Education
Opening eyes with visual fixation should improve symptoms, whereas closing eyes may make symptoms worse. Otherwise, encourage activity as tolerated. Minimize rapid head movement until symptoms resolve. Avoid vestibular suppressants long term because this can inhibit central compensation.

Prognosis
Prognosis depends on cause of labyrinthitis.

Complications
Permanent hearing loss, more common with bacterial causes, and chronic impairment of balance.

Ménière Disease; Postconcussion Syndrome (Mild Traumatic Brain Injury); Tinnitus

CODES

ICD10
- H83.09 Labyrinthitis, unspecified ear
- H83.01 Labyrinthitis, right ear
- H83.02 Labyrinthitis, left ear

CLINICAL PEARLS
- Ask patients to describe symptoms in their own words; alternative symptoms include light-headedness, vertigo, disequilibrium, or imbalance.
- Benzodiazepines are better vestibular suppressants and are preferred over antihistamine/anticholinergics such as meclizine. Vestibular suppressants should be used for short duration only because these will delay central compensation.
- Episodic vertigo tends to be caused by BPPV or Ménière disease, whereas persistent vertigo with sensorineural hearing loss and tinnitus is more consistent with labyrinthitis. Vestibular neuritis would be considered if there was no hearing involvement.
BASICS

DESCRIPTION

- Lactose intolerance is a syndrome of abdominal pain, bloating, and flatulence after the ingestion of lactose.
- Lactose malabsorption results from a reduction in lactase activity in the brush border of the small intestinal mucosa.
- Lactase activity peaks at birth then decreases after the first few months of life, declining continuously throughout life. 75% of adults worldwide exhibit a decline in lactase activity after birth. Only 50% of lactase activity is needed to digest lactose without causing symptoms of lactose intolerance.
  - Congenital lactose intolerance: very rare
  - Primary lactose intolerance: common in adults who develop low lactase levels after childhood
  - Secondary lactose intolerance: inability to digest lactose caused by any condition injuring the intestinal mucosa (e.g., infectious enteritis, celiac disease, eosinophilic gastroenteritis, or inflammatory bowel disease) or a reduction of available mucosal surface (e.g., resection)
- Lactose malabsorption may be asymptomatic and is equally common in healthy patients and in those with functional bowel disorders.
- System(s) affected: endocrine/metabolic, gastrointestinal

Pediatric Considerations

- Primary lactose intolerance begins in late childhood.
- No consensus on whether young children (<5 years of age) should avoid lactose following diarrheal illness
- Lactose-free formulas are available.
- Exclude milk protein allergy.

EPIDEMIOLOGY

Incidence

- ≥50% of infants with acute or chronic diarrheal disease have lactose intolerance; particularly common with rotavirus infection
- Lactose intolerance is common with giardiasis, ascariasis, irritable bowel syndrome (IBS), tropical and nontropical sprue, and AIDS malabsorptive syndrome.

Prevalence

- In South America, Africa, and Asia, rates of lactose intolerance are >50%.
- In the United States, the prevalence is 15% among whites, 53% among Hispanics, and 80% among African Americans.
- In Europe, lactose intolerance varies from 15% in Scandinavian countries to 70% in Italy.
- Predominant age:
  - Primary: teenage and adult
  - Secondary: depends on underlying condition
ETIOLOGY AND PATHOPHYSIOLOGY
- Primary lactose intolerance: The normal decline in lactase activity in the intestinal mucosa is genetically determined and permanent after weaning from breast milk.
- Secondary lactose intolerance: associated with gastroenteritis in children; also associated with any gastrointestinal infection or inflammation of the small intestine with resultant lactose malabsorption in both adults and children

Genetics
- In whites, lactase deficiency is associated with a single nucleotide polymorphism (SNP) consisting of a nucleotide switch of T for C 13910 bp on chromosome 2. This results in variants of CC-13910 (lactase nonpersistence) OR CT-13910/TT-13910 (lactase persistence) (1).
- SNP (C/T-13910) is associated with lactase persistence in northern Europeans.
- Other SNPs (G/C-14010, T/G-13915, and C/G-13907) have been linked to lactase persistence in some patients of African descent.

RISK FACTORS
- Adult-onset lactase deficiency has wide geographic variation.
- Age:
  - Signs and symptoms usually do not become apparent until after age 6 to 7 years.
  - Symptoms may not be apparent until adulthood, depending on dietary lactose intake and rate of decline of intestinal lactase activity.
  - Lactase activity correlates with age, regardless of symptoms.

GENERAL PREVENTION
Lactose avoidance relieves symptoms. Patients can learn what level of lactose is tolerable in their diet.

COMMONLY ASSOCIATED CONDITIONS
- Tropical or nontropical sprue
- Giardiasis
- IBS or other functional bowel disorders
- Small intestinal bacterial overgrowth (SIBO)
- Celiac disease

DIAGNOSIS
- Lactose intolerance can be presumed in patients manifesting mild symptoms after ingestion of significant amounts of lactose (such as >2 servings of dairy per day), with resolution of symptoms after avoidance of lactose-containing foods for 1 week.
- A positive lactose hydrogen breath test is confirmatory.
- Lactose intolerance can mimic symptoms of functional gastrointestinal disorders. Lactose intolerance can also be a coexisting condition.

HISTORY
- Assess daily lactose consumption.
A single dose of lactose (12 g, equivalent to 1 cup of milk) consumed alone produces no or minor symptoms in persons with lactose intolerance.

- Lactose doses of 15 to 18 g are well tolerated with other nutrients. Doses >18 g cause progressively more symptoms, and quantities >50 g elicit symptoms in most individuals.
- Symptoms arise 30 minutes to 2 hours after consumption of lactose-containing products.
- Symptoms include bloating, flatulence, cramping abdominal discomfort, and diarrhea or loose stools. Vomiting may be noted in adolescents.
- Abdominal pain may be crampy in nature and often is localized to the periumbilical area or lower quadrant.
- Stools usually are bulky, frothy, and watery, although diarrhea may be rare in adults.
- Only 20–30% of individuals with lactose malabsorption develop symptoms.

**PHYSICAL EXAM**

- Vital signs and general appearance are typically normal.
- Audible bowel sounds (borborygmi) on physical examination (may be particularly bothersome to the patient). The exam is otherwise typically normal or nonspecific.

**DIFFERENTIAL DIAGNOSIS**

- Functional GI disorder (e.g., IBS)
- SIBO
- Celiac disease
- Inflammatory bowel disease
- Infectious enteritis such as giardiasis
- Drug or radiation induced enteritis
- Sucrase deficiency
- Cow’s milk protein allergy

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- The lactose breath test (LBT) is a confirmatory for lactose intolerance. It is noninvasive, easy to perform (sensitivity 78%; specificity 98%) (2).
- Intestinal bacteria digest carbohydrates and produce measurable hydrogen and methane in expired breath:
  - Administer lactose when fasting (2 g/kg; max dose 25 g in children; 50 g in adults). Note any symptoms; sample breath hydrogen at baseline and at 30-minute intervals for 3 hours. Compare postlactose and baseline values. A rise in hydrogen concentration value of 20 ppm over baseline is diagnostic for lactose malabsorption. An early peak (15 to 30 minutes) suggests SIBO.
- Small bowel biopsy for histology and direct measurement of lactase activity (rarely needed).
- A positive LBT confirms lactose malabsorption but does not determine etiology.

**Diagnostic Procedures/Other**

- Lactose tolerance test is an alternative to LBT in adults and measures lactose absorption through serum glucose measurements. Following oral administration of a 50-g test dose in adults (2 g/kg in children), blood glucose levels are monitored at 0, 60, and 120 minutes. An increase in blood glucose of <20 mg/dL (1.1 mmol/L) with the concurrent development of symptoms is diagnostic. False-negative results may occur in patients with diabetes or bacterial overgrowth.
Stool electrolyte testing, if done, may indicate a stool osmotic gap >125 mOsm/kg, although this is not specific to lactose intolerance.

**Test Interpretation**
Low lactase enzyme activity in intestinal mucosa, tested by small bowel biopsy, may be patchy or focal.

**TREATMENT**
There is insufficient evidence to recommend any particular treatment (including probiotics, colonic adaptation, and other supplements) as definitive first line.

- In the absence of a correctable underlying disease, treatment includes four general principles (3)[B].
  - Avoid milk/dairy products to improve symptoms.
  - Up to 12 to 15 g of lactose can be tolerated in without significant symptoms (1 cup of milk).
  - Gradually reintroduce lactose as symptoms allow. Spreading lactose servings throughout the day improves tolerance.
  - If symptoms persist, substitute fermented and matured milk products for lactose.
- Certain strains, concentrations, and preparations of probiotics may alleviate symptoms.
- Incrementally increasing doses of lactose to induce adaptation have limited success.
- Insufficient evidence to routinely recommend lactose-reduced or hydrolyzed milk, lactase supplements taken with milk or probiotics.
- Maintain calcium and vitamin D intake.

**MEDICATION**
**First Line**
Lactase (Lactaid, Lactrase):
- Commercially available “lactase” preparations are bacterial or yeast β-galactosidases.
- Take 1 to 2 capsules or tablets prior to ingesting dairy products.
- Effectiveness at preventing symptoms varies.
- Can add tablets or contents of capsules to milk (1 to 2 caps/tabs per quart of milk) before drinking; also commercially available in milk in some areas.
- Not effective for all people with lactose intolerance.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Certain probiotic formulations taken with meals may alleviate some symptoms of lactose intolerance (4)[B].

**ONGOING CARE**
**DIET**
- Reduce or restrict dietary lactose to control symptoms—patient-specific “trial and error.”
- Yogurt and fermented products such as hard cheese are often better tolerated than milk.
- Supplement calcium (e.g., calcium carbonate).
- Prehydrolyzed milk (Lactaid) is available.
PATIENT EDUCATION

- Read labels on commercial products—milk sugar is used in many products and may cause symptoms.
- Patients may tolerate whole milk or chocolate milk better than skim milk (slower rate of gastric emptying)
- Lactose consumed with other food products is better tolerated than when consumed with milk alone.
- Primary lactase deficiency is permanent; secondary lactose intolerance usually is temporary, although it may persist for months after the inciting event.
- 20% of prescription drugs and 6% of over-the-counter (OTC) medicines may contain lactose as a base.
- Most patients with lactose intolerance or malabsorption can tolerate 12 to 15 g of lactose per day.

PROGNOSIS

- Normal life expectancy
- Symptoms can be controlled through diet alone if lactase tablets are ineffective.

COMPLICATIONS

Calcium deficiency: Avoidance of milk and other dairy products can lead to reduced calcium intake, which may increase the risk for osteoporosis and fracture.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- E73.9 Lactose intolerance, unspecified
- E73.8 Other lactose intolerance
- E73.1 Secondary lactase deficiency

CLINICAL PEARLS

- The diagnosis of lactose intolerance is based on clinical history and confirmed by hydrogen breath testing.
- Most lactose-intolerant patients can tolerate up to 12 to 15 g of lactose per day (equivalent to 1 cup of milk).
- Lactose-intolerant patients may tolerate yogurt and fermented products better than milk and cheese.
- A diary helps identify problematic foods.
- Patients should read ingredient labels to look for milk, lactose, whey, and curd.
- Lactose-intolerant patients may tolerate whole milk or chocolate milk better than skim milk due to a slower rate of gastric emptying.
- Many patients with lactose intolerance unnecessarily avoid all dairy products, potentially causing an inadequate intake of calcium and vitamin D.
LARYNGITIS
Karlynn Sievers, MD

BASICS

DESCRIPTION
- Laryngitis is inflammation, erythema, and edema of the mucosa of the larynx and/or vocal cords characterized by hoarseness, loss of voice, throat pain, coughing, and often a negative impact on a person’s quality of life and daily activities.
- There is a range of severity, but most cases are acute and are associated with viral upper respiratory infection, irritation, or acute vocal strain.
- System(s) affected: pulmonary; ears, nose, throat (ENT)
- Synonym(s): acute laryngitis; chronic laryngitis; croup or laryngotracheitis (in children)

EPIDEMIOLOGY
- Predominant age: affects all ages
- Children more susceptible than adults due to increased risk of symptomatic inflammation from smaller airways
- Predominant sex: male = female

Incidence
Common

Prevalence
Common; approximately 1.7% of population have dysphonia with 50% of this being caused by acute laryngitis. Prevalence rates are increasing but difficult to calculate because many patients do not seek medical attention.

ETIOLOGY AND PATHOPHYSIOLOGY
- Misuse or abuse of voice
- Infectious
  - Viral: influenza A, B; parainfluenza; adenovirus; coronavirus; rhinovirus; human papillomavirus; cytomegalovirus; varicella-zoster virus; herpes simplex virus; respiratory syncytial virus; coxsackievirus
  - Fungal: uncommon but thought to be underdiagnosed, potentially accounting for up to 10% of presentations in both immunocompromised and immunocompetent patients; risk factors include recent antibiotic or inhaled corticosteroid use (1): histoplasmosis, blastomycosis, Coccidioides, Cryptococcus, and Candida.
  - Bacterial (uncommon): β-hemolytic streptococcus, Streptococcus pneumoniae, Haemophilus influenzae, tuberculosis (TB), leprosy, Moraxella catarrhalis, Mycoplasma pneumoniae, Chlamydophila pneumoniae. In patients with chronic laryngitis, MRSA (methicillin-resistant Staphylococcus aureus) should be considered as a potential cause (2).
  - Secondary syphilis if left untreated
  - Leprosy (in 30–55% of those with leprosy, larynx is affected; in tropical and warm countries)
- Irritants
- Inhalation of irritating substances (e.g., air pollution, cigarette smoke)
- Aspiration of caustic chemicals
- Gastroesophageal reflux disease (GERD)/laryngopharyngeal reflux disease (LPRD)
- Excessively dry environment
- Allergy exposures (including pollens)

- Anatomic
  - Aging changes: muscle atrophy, loss of moisture in larynx, and bowing of vocal cords
  - Vocal cord nodules/polyps (“singer’s nodes”)
  - Local cancer

- Iatrogenic: inhaled steroids such as those used to treat asthma, surgical injury, endotracheal intubation injury

- Idiopathic
  - Neuromuscular disorder (e.g., myasthenia gravis); stroke
  - Rheumatoid arthritis
  - Trauma (e.g., blunt or penetrating trauma to neck)

**RISK FACTORS**

- Acute:
  - Infection or trauma
  - Upper respiratory tract viral infection (e.g., influenza, rhinovirus, adenovirus, parainfluenza)
  - Voice overuse—excess talking, singing, or shouting
  - Pneumonia—viral or bacterial
  - Coughing
  - Lack of immunization for pertussis or diphtheria
  - Immunocompromised
  - Recent endotracheal intubation or local surgery

- Chronic (persists beyond 3 weeks):
  - Allergic laryngitis (3)
  - Chronic rhinitis/sinusitis
  - Voice abuse
  - GERD/LPRD (1)
  - Smoking: primary or secondhand
  - Excessive alcohol use
  - Autoimmune disorders (e.g., rheumatoid arthritis) (1)
  - Granulomatous diseases (e.g., sarcoidosis) (1)
  - Stroke
  - Environmental pollution; constant exposure to dust or other irritants such as chemicals at workplace
  - Medications: inhaled steroids, anticholinergics, antihistamines, anabolic steroids

**Geriatric Considerations**
May be more ill, slower to heal; need to consider neoplasm

**Pediatric Considerations**
- Common in this age group
- Consider congenital/anatomic causes.

**GENERAL PREVENTION**
Avoid overuse of voice (speech therapy/voice training is helpful for vocal musicians/public speakers).
Influenza virus vaccine is recommended.
Quit smoking and avoid secondhand smoke.
Limit or avoid alcohol/caffeine/acidic foods.
Control GERD/LPRD.
Maintain proper hydration status.
Avoid allergens.
Wear mask around chemical/environmental irritants.
Good hand washing (infection prevention)

COMMONLY ASSOCIATED CONDITIONS
- Viral pharyngitis
- Diphtheria (rare): Membrane can descend into the larynx.
- Pertussis: larynx involved as part of the respiratory system
- Bronchitis
- Pneumonitis
- Croup, epiglottitis, in children

DIAGNOSIS

HISTORY
- Hoarseness, throat “tickle,” dry cough, and rawness
- Dysphonia (abnormal-sounding voice)
- Constant urge to clear the throat
- Possible fever
- Malaise
- Dysphagia/odynophagia
- Regional cervical lymphadenopathy
- Stridor or possible airway obstruction in children
- Cough may be worse at night in children.
- Hemoptysis
- Laryngospasm or sense of choking
- Allergic rhinitis/rhinorrhea/postnasal drip (PND)
- Occupation or other reasons for voice overuse
- Smoking history
- Blunt or penetrating trauma to neck
- GERD/LPRD

PHYSICAL EXAM
- Head and neck exam, including airway patency, cervical nodes; cranial nerve exam
- Visualization of the larynx: preferably with a flexible or rigid endoscope or with an indirect mirror examination as a screening technique to dictate further appropriate testing
- Note quality of voice (i.e., hoarse, breathy, wet, “hot potato–like,” asthenic [weak], strained)

DIFFERENTIAL DIAGNOSIS
Diphtheria
Vocal nodules or polyps
Laryngeal malignancy
Thyroid malignancy
Upper airway malignancy (3,4)[A]
Epiglottitis
Pertussis
Laryngeal nerve trauma/injury
Foreign body (in children)
Autoimmune (rheumatoid arthritis)

**DIAGNOSTIC TESTS & INTERPRETATION**

- Rarely needed
- White blood cells elevated in bacterial laryngitis
- Viral culture (seldom necessary)

**Follow-Up Tests & Special Considerations**

- Barium swallow, only if needed for differential diagnosis
- CT scan if foreign body suspected
- Do not offer CT imaging before visualization of the larynx with laryngoscopy (5)

**Diagnostic Procedures/Other**

- Fiber-optic or indirect laryngoscopy: looking for red, inflamed, and occasionally hemorrhagic vocal cords; rounded edges and exudate (Reinke edema)
- Consider otolaryngologic evaluation and biopsy: laryngitis lasting >2 weeks in adults with history of smoking or alcohol abuse, to rule out malignancy.
- pH probe (24-hour): no difference in incidence of pharyngeal reflux as measured by pH probe between patients with chronic reflux laryngitis and healthy adults (3)[A]
- Video stroboscopy laryngoscopy for diagnosis of subtle lesions (e.g., vocal cord nodules or polyps) (4)[A]

**TREATMENT**

- Limited but good evidence that treatment beyond supportive care is ineffective (4)[A]
- Supportive care consists of hydration, voice rest, humidification, and limitation of caffeine (1) [A].
- Antibiotics appear to have no benefit in acute laryngitis because etiologies are predominantly viral (1,6)[A]. In chronic laryngitis, consider bacterial sources such as MRSA (2,5).
- Corticosteroids in severe cases of laryngitis to reduce inflammation such as croup
- May need voice training, if voice overuse (5)
- Nebulized epinephrine reduces croup symptoms 30 minutes posttreatment; evidence does not favor racemic epinephrine or L-epinephrine or IPPB over simple nebulization. Racemic epinephrine reduces croup symptoms at 30 minutes, but effect lasts only 2 hours (6)[A].
- Botulinum toxin injections for spasmodic dysphonia (5)

**GENERAL MEASURES**

- Acute:
– Usually a self-limited illness lasting <3 weeks and not severe
– Antibiotics of no value (6)[A]
– Avoid excessive voice use, including whispering.
– Steam inhalations or cool-mist humidifier
– Increase fluid intake, especially in cases associated with excessive dryness.
– Avoid smoking (or secondhand exposure).
– Warm saltwater gargles

• Chronic:
  – Symptomatic treatment as above
  – Voice therapy (for patients with intermittent dysphagia and vocal abuse)
  – Smoking cessation
  – Reduction or cessation of alcohol intake
  – Occupational change or modification, if exposure driven
  – Allergen avoidance
  – Consider discontinuing offending medication (e.g., inhaled steroids) (6)[A].
• Reflux laryngitis: elevate head of bed, diet changes, other antireflux lifestyle change
management; proton pump inhibitors (1)[A]

MEDICATION
Usually none

First Line
• Analgesics
• Antipyretics (rare)
• Cough suppressants
• Throat lozenges
• Plenty of fluids

Second Line
• Inhaled corticosteroids (consider only if allergy induced) (3)
• Oral corticosteroids: only if urgent need in adults (presenter, singer, actor)
• Oral corticosteroids: Evidence of benefit has been studied with single-dose dexamethasone in children ages 6 months to 5 years for moderate-severity croup; reduces symptoms within 6 hours; reduces hospitalizations, hospital length of stay, and revisits to office (6)[A]
• Standard of care is to prescribe proton pump inhibitors for chronic laryngitis if GERD or LPRD is suspected; however, evidence suggests only a modest benefit, if any (1)[A].
• Treat nonviral infectious underlying causes.
• Candidal laryngitis:
  – Mild cases: oral antifungal (fluconazole)
  – Amphotericin B or echinocandin can be given in life-threatening cases (1)[A].

ISSUES FOR REFERRAL
• Immediate emergency ENT referral for patients with stridor or respiratory distress (1)[A]
• ENT referral for persistent symptoms (>2 to 3 weeks) or concern for foreign body
• Consider otolaryngologic evaluation and biopsy for laryngitis lasting >3 weeks in adults, especially in those with history of smoking or alcohol abuse to rule out malignancy.
• Consider GI consult to rule out GERD/LPRD.
SURGERY/OTHER PROCEDURES
- Vocal cord biopsy of hyperplastic mucosa and areas of leukoplakia if cancer or TB is suspected
- Removal of nodules or polyps if voice therapy fails

COMPLEMENTARY & ALTERNATIVE MEDICINE
Some experts, although not well studied, have recommended the following:
- Barberry, black currant, Echinacea, Eucalyptus, German chamomile, goldenrod, goldenseal, warmed lemon and honey, licorice, marshmallow, peppermint, saw palmetto, slippery elm, vitamin C, zinc

ONGOING CARE

PATIENT EDUCATION
- Educate on the importance of voice rest, including whispering.
- Provide assistance with smoking cessation.
- Help the patient with modification of other predisposing habits or occupational hazards.

PROGNOSIS
Complete clearing of the inflammation without sequelae

COMPLICATIONS
Chronic hoarseness

REFERENCES

ADDITIONAL READING
CODES

ICD10
- J04.0 Acute laryngitis
- J37.0 Chronic laryngitis
- J04.2 Acute laryngotracheitis

CLINICAL PEARLS
- Laryngitis is usually self-limited and needs only comfort care. Standard treatment is voice rest, hydration, humidification, and limit caffeine intake.
- Refer to ENT for direct visualization of vocal cords for prolonged laryngitis.
- Corticosteroids have some benefits for children with moderately severe croup.
- Voice training useful for chronic laryngitis
LEAD POISONING
Jason Chao, MD, MS

**BASICS**

**DESCRIPTION**
- Disease resulting from a high body burden of lead (Pb)—an element with no known physiologic value
- Synonym(s): lead poisoning, inorganic

**EPIDEMIOLOGY**
- Predominant age: 1 to 5 years, adult workers
- Predominant sex: male > female (1:1 in childhood)

**Prevalence**
- Centers for Disease Control and Prevention (CDC) estimates half a million U.S. children aged 1 to 5 years have blood Pb levels >5 μg/dL. Levels vary among communities and populations.
- In 2016, 12,574 children in the United States were noted with a blood Pb level ≥10 μg/dL, down from 17,246 in 2012.
- CDC estimates suggest that between 2008 and 2010, the introduction of lead poisoning prevention programs reduced the number of children with blood lead levels over ≥1 μg/dL by nearly 3 million.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Inhalation of Pb dust or fumes, or ingestion of Pb
- Pb replaces calcium in bones. Pb interferes with heme synthesis, causes interstitial nephritis, and interferes with neurotransmitters, especially glutamine; high levels affect blood–brain barrier and lead to encephalopathy, seizures, and coma.
- Pb crosses blood–brain barrier by displacing calcium ions—developing nervous system is particularly vulnerable to toxic effects of lead.
- Early life Pb exposure causes methylation changes leading to epigenetic alterations that may predispose to brain dysfunction.

**RISK FACTORS**
- Children with pica or with iron-deficiency anemia
- Residence in or frequent visitor to deteriorating pre-1960 housing with Pb-painted surfaces or recent renovation
- Soil/dust exposure near older homes, Pb industries, or urban roads
- Sibling or playmate with current or past Pb poisoning
- Dust from clothing of Pb worker or hobbyist
- Pb dissolved in water from Pb or Pb-soldered plumbing (e.g., Flint, Michigan 2014 to 2015)
- Pb-glazed ceramics leachate (especially with acidic food or drink)
- Folk remedies, spices, and cosmetics
  - Mexico: azarcon, greta
  - Dominican Republic: litargirio, a topical agent
  - Asia and Middle East: chuifong tokuwan, pay-loo-ah, ghasard, bali goli, kandu, Ayurvedic
herbal medicine from South Asia, kohl (al-kahal, ceruse, surma), saoott, cebagin
- Hobbies: target shooting, glazed pottery making, Pb soldering, preparing Pb shot or fishing sinkers, stained-glass making, car/boat repair, home remodeling
- Occupational exposure: plumbers, pipe fitters, Pb miners, auto repairers, glass manufacturers, ship builders, printer operators, plastic manufacturers, Pb smelters and refiners, steel welders or cutters, construction workers, rubber product manufacturers, battery manufacturers, bridge reconstruction workers, firing range workers, military, and law enforcement
- Dietary: zinc or calcium deficiency
- Imported toys with Pb
- Retained bullet fragments, especially in joints

**Pediatric Considerations**
- Children are at increased risk because of incomplete development of the blood–brain barrier prior to 3 years of age (allowing more Pb into the central nervous system [CNS]).
- Ingested Pb has 40% bioavailability in children (10% in adults).
- Common childhood behaviors such as frequent hand-to-mouth activity and pica (repeated ingestion of nonfood products) increase the risk of Pb ingestion.

**Pregnancy Considerations**
Cross-sectional studies suggest an association between elevated blood Pb and preeclampsia.

**GENERAL PREVENTION**
- Counsel families on sources of Pb and how to decrease exposure. Screen high-risk children (1)[C].
- Warn parents about unsafe home renovations.
- Wet mopping and dusting with a high-phosphate solution (e.g., powdered automatic dishwasher detergent with 1/4 cup per gallon of water) helps control Pb-bearing dust. High-phosphate detergent is no longer available in some states.
- If tap water is potentially Pb contaminated, use cold water instead of hot water and run for 30 to 60 seconds to flush pipes. Use Pb-free water source if possible (bottled or distilled water).
- Screen at-risk pregnant women (2)[C].

**COMMONLY ASSOCIATED CONDITIONS**
Iron-deficiency anemia

**DIAGNOSIS**

**HISTORY**
- Often asymptomatic
- Mild-to-moderate toxicity
  - Myalgias, paresthesias, fatigue, irritability, lethargy
  - Abdominal discomfort, arthralgia, difficulty concentrating, headache, tremor, vomiting, weight loss, muscular exhaustibility
- Severe toxicity: three major clinical syndromes:
  - Alimentary type: anorexia, metallic taste, constipation, severe abdominal cramps due to intestinal spasm and sometimes associated with abdominal wall rigidity
  - Neuromuscular type (characteristic of adult plumbism): peripheral neuritis, usually painless
and limited to extensor muscles
– Cerebral type or Pb encephalopathy (more common in children): seizure, coma, and long-term sequelae, including neurologic defects, delayed mental development, and chronic hyperactivity (or other behavioral changes)
– Adults may also present with decreased libido, erectile dysfunction
• Chronic exposure may cause renal failure.

PHYSICAL EXAM
• Often normal, but abdominal tenderness may be severe. Neurologic exam may reveal neuropathy or encephalopathy.
• Historical findings include “crackpot skull”—resonant cranium secondary to hydrocephalus; lead line on gingival border and wrist drop (peripheral neuropathy)

DIFFERENTIAL DIAGNOSIS
• Alimentary type may present as acute abdomen.
• Neuromuscular type presents similar to other polyneuropathies.
• May be confused with attention deficit disorder, intellectual disability, autism, dementia, and other causes of seizures
• Elevated erythrocyte protoporphyrin may be caused by iron-deficiency anemia or (less commonly) hemolytic anemia.
• Erythropoietic protoporphyria produces a very high erythrocyte protoporphyrin level.

DIAGNOSTIC TESTS & INTERPRETATION
• Venous blood reference value Pb >5 μg/dL (0.24 μmol/L). CDC is considering lowering the reference value to >3.5 μg/dL (0.17 μmol/L).
• Confirm screening capillary Pb levels >5 μg/dL (0.24 μmol/L) with a venous sample.
• Hemoglobin and hematocrit slightly low; eosinophilia; basophilic stippling on peripheral smear (not diagnostic of Pb toxicity)
• Renal function is decreased in late stages.
• Abdominal radiograph for Pb particles in gut if recent ingestion is suspected
• Radiograph of long bones may show metaphyseal changes (resulting from growth arrest). Films are not routinely recommended.

</tr>
</tbody>
</table>

ALERT
• For Pb levels above 5 μg/dL, confirm with repeat testing according to the table.
• For blood Pb levels persistently >15 μg/dL, contact local public health department for home inspection.
• For any elevated level, educate on sources of Pb exposure.
- Pb level 5–45: complete history and physical exam, follow-up Pb monitoring; complete inspection of home or workplace to determine source of Pb and Pb-hazard reduction; neurodevelopmental monitoring: iron status, hemoglobin, or hematocrit (3)[C]
- Pb level 45 to 69 μg/dL: treatment to lower level plus free erythrocyte protoporphyrin, oral chelation therapy, or hospitalization if Pb-safe environment cannot be ensured (3)[C]
- Pb >70 μg/dL: Hospitalize for chelation therapy (4)[C].

**GENERAL MEASURES**
Remove child from source of exposure.

**MEDICATION**
- Consider oral chelation for asymptomatic and Pb >45 and <70; chelation (preferably parenteral) for Pb >70 or symptomatic Pb <70 (4)[C]
- Do not begin chelation until Pb particles present in gut are cleared (5).

**First Line**
- Oral chelation: succimer (Chemet), dimercaptosuccinic acid (DMSA) 350 mg/m² or 10 mg/kg q8h for 5 days and then q12h for 2 weeks. This may be repeated after 2 weeks off if Pb levels are not stabilized at <15 μg/dL (<0.72 μmol/L) (4)[C].
- Parenteral chelation (begin after establishment of adequate urine output):
  - Dimercaprol (British anti-Lewisite [BAL]) 75 mg/m² given deep IM, then BAL 450 mg/m²/day divided q4h for 5 days plus Ca edetate calcium disodium (EDTA) 1,500 mg/m²/day continuous IV infusion for 5 days. If rebound Pb level ≥45 μg/dL (>2.17 μmol/L), chelation may be repeated after 2-day interval if symptomatic or after 5-day interval if asymptomatic.
  - Ca EDTA 1,000 mg/m²/day for 5 days; may be repeated after 5 to 7 days
- Diazepam for initial control of seizures; further control maintained with paraldehyde
- Contraindications: Do not give BAL to patients with a peanut allergy (the drug solution contains peanut oil).
- Precautions
  - Succimer: GI upset, rash, nasal congestion, muscle pains, elevated liver function tests
  - BAL: nausea, vomiting, fever, headache, transient hypertension, hepatocellular damage
  - Ca EDTA: renal failure; increased excretion of zinc, copper, and iron
- Significant possible interactions
  - Do not give vitamins with oral chelation.
  - BAL may precipitate hemolytic crisis in a patient with glucose-6-phosphate dehydrogenase deficiency.

**Second Line**
Oral chelation with penicillamine (D-penicillamine, Depen, Cuprimine) (5)
- Penicillin-allergic patient should not receive penicillamine (cross-sensitivity is common).
- 10 to 15 mg/kg/day given BID mixed in apple juice/sauce on empty stomach (not FDA-approved)
- Penicillamine may cause GI upset, renal failure, granulocytopenia, liver dysfunction, iron deficiency, and drug-induced lupus-like syndrome.

**ISSUES FOR REFERRAL**
Consider consultation if parenteral chelation is required.

**ADDITIONAL THERAPIES**
Remove patient from potential source of Pb if Pb level >45 until complete home inspection is performed.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Garlic has been used to treat mild to moderate Pb poisoning in adults.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Blood Pb level >70 μg/dL
- If symptomatic, blood Pb level >35 μg/dL
- Outpatient care unless parenteral chelation or immediate removal from contaminated environment is required
- If Pb source is in the home, the patient must reside elsewhere until the abatement process is completed.
- Avoid visit to any site of potential contamination.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Check for rebound Pb level 7 to 10 days after chelation therapy. Monitor biweekly or monthly thereafter.
- Correct iron or other detected nutritional deficiencies.
- Once Pb <35 μg/dL, repeat testing every 1 to 3 months until level <25 μg/dL is achieved. Then, monitor every 3 to 6 months until level <10 μg/dL. Once <9 μg/dL, test every 6 to 9 months (3)[C].

**DIET**
- If symptomatic, avoid excessive fluids.
- Avoid pica.
- Adequate calcium, iron, zinc, and vitamin C to reduce absorption and retention of Pb (5)

**PATIENT EDUCATION**
- U.S. Environmental Protection Agency. Lead. https://www.epa.gov/lead
- National Safety Council, 1121 Spring Lake Drive, Itasca, IL 60143-3201; 800-621-7615; http://www.nsc.org/learn/safety-knowledge/Pages/Lead-Poisoning-Prevention.aspx

**PROGNOSIS**
- Symptomatic Pb poisoning without encephalopathy generally improves with chelation, but subtle CNS toxicity may be long-lasting or permanent.
- Preschool children with higher Pb levels have lower reading and math scores in elementary school.
- Children with high Pb levels at age 11 years have lower IQ score and socioeconomic status in
adulthood.

- With Pb encephalopathy, permanent sequelae (e.g., mental retardation, seizure disorder, blindness, and hemiparesis) occurs in 25–50%.

**COMPLICATIONS**

- CNS toxicity may be long-lasting or permanent.
- Long-term Pb exposure may cause chronic renal failure (Fanconi-like syndrome), gout, or Pb line (blue–black) on gingival tissue.
- Pb exposure in pregnancy is associated with reduced birth weight and premature birth.

Anemia, Iron Deficiency

**CODES**

ICD10
CLINICAL PEARLS

- Screen the following children:
  - 6 to 11 months of age with ≥1 risk factors:
    - Living in or visit a house built before 1960 with peeling paint or recent renovation
    - Sibling/playmate with elevated Pb
    - Living with adult with job or hobby involving Pb
    - Living near industry likely to release Pb
  - Children living in high-risk communities (>12% elevated Pb) should be tested annually from 1 to 5 years of age.
  - Newly arrived refugees
- There is no clear safe Pb level. Many experts consider Pb levels >3.5 μg/dL as elevated.
- There are no studies that show benefit of chelation for asymptomatic children with Pb <45. Removal of sources of Pb within the environment is critical.
LEGIONNAIRES’ DISEASE
Kenneth A. Ballou, MD, FAAFP ♦ Jason Domagalski, MD ♦ Benjamin Bring, DO

BASICS

DESCRIPTION
- Legionnaires’ disease was named for an epidemic of lower respiratory tract disease at an American Legion convention in Philadelphia in 1976. The previously unrecognized causative bacterium was isolated, identified, and named Legionella pneumophila. The organism primarily causes pneumonia and flulike illness. Legionella preferentially colonizes commercial water systems (e.g., hotels, hospitals, apartment buildings, air conditioning cooling towers).
- It is one of the three most common causes of pneumonias and the most common atypical pneumonia.
- System(s) affected: pulmonary, gastrointestinal (GI)
- Synonym(s): Legionella pneumonia; legionellosis; Pontiac fever (self-limited flulike illness without pneumonia caused by Legionella species)

EPIDEMIOLOGY
- Predominant age: 15 months to 84 years; 74–91% of patients are >50 years old.
- Predominant gender: male > female

Incidence
- U.S. cases of Legionnaires’ disease have increased 4-fold since 2000; >6,000 cases reported in 2016 [1]
- Outbreaks most common in late summer/early fall
- ~2–9% of all cases of pneumonia in the United States

ETIOLOGY AND PATHOPHYSIOLOGY
- L. pneumophila is a weak gram-negative aerobic saprophytic freshwater bacterium. It is widely distributed in soil and water. Bipolar flagella provide motility; grow optimally at 40–45°C (104–122°F)
- Exists in nature as a protozoan parasite, often within fresh water biofilms
- Serogroups 1 to 6 account for clinical disease.
- Serogroup 1 represents 70–92% of all clinical cases of Legionella in the United States.
- In the lung, Legionella infects alveolar macrophages.
- The organism is transmitted by breathing in contaminated water droplets or by aspiration of contaminated water (e.g., contaminated shower water was responsible for the inaugural Philadelphia outbreak).
- Recently, community outbreaks have been associated with whirlpools, spas, fountains, and aboard cruise ships

RISK FACTORS
- Impaired cellular immunity (Legionella are intracellular pathogens.)
- Male gender
- Smoking; alcohol abuse
• Immunosuppression; HIV; diabetes; organ transplant recipients; corticosteroid use
• Chronic cardiopulmonary disease
• Advanced age
• Use of antimicrobials within the past 3 months

GENERAL PREVENTION
• Not transmitted person to person (Respiratory isolation is unnecessary.)
• Superheat and flush water systems: Heat water to at least 70°C (158°F) and flush for 30 minutes (2)[C].
• Ultraviolet light and copper–silver ionization are bactericidal.
• Monochloramine disinfection of municipal water supplies decreases risk for Legionella infection.
• 0.2 micron water filters—must change regularly
• Keep water heaters >60°C (>140°F), cold water <20°C (<68°F).

DIAGNOSIS
• Illness ranges from asymptomatic seroconversion and mild febrile illness to severe pneumonia.
• Wound infections with Legionella also reported
• Incubation period is 2 to 14 days.

HISTORY
• Signs and symptoms (with associated percentage):
  – Cough: 92% (typically dry; rarely productive)
  – Fever/chills: 90%
  – Dyspnea: 62%
  – Pleuritic chest pain: 35%
  – Headache: 48%
  – Myalgia/arthralgia: 40%
  – Watery diarrhea: 50%
  – Nausea and vomiting: 49%
  – Neuropsychiatric symptoms include encephalopathy, confusion, disorientation, obtundation, depression, hallucinations, insomnia, and seizure: 53%
• History of immunosuppression increases risk.

PHYSICAL EXAM
• Fever
• Relative bradycardia (key sign)
  – Temperature ≥102°F with an inappropriately low pulse pressure <100 beats/min (Normal compensatory reaction to fever is >110 beats/min.)
• Rales and signs of consolidation (i.e., pectoriloquy, egophony, or tactile fremitus)

DIFFERENTIAL DIAGNOSIS
• Other bacterial pneumonias, especially atypical pneumonias: Mycoplasma pneumoniae, Q fever (Coxiella burnetii), Chlamyphila pneumoniae, Chlamyphila psittaci, Francisella tularensis
• Viral pneumonias, such as adenovirus, influenza (human, avian, swine), cytomegalovirus
DIAGNOSTIC TESTS & INTERPRETATION

Indications for Legionella testing:
- Failed outpatient antibiotic treatment for community-acquired pneumonia (CAP)
- Severe pneumonia, particularly those requiring intensive care
- Immunocompromised patients with pneumonia
- Patients with a history of traveling away from their home within 10 days of illness onset
- Pneumonia in the setting of a known Legionnaires’ disease outbreak
- Pneumonia beginning ≥48 hours after hospital admission

Initial Tests (lab, imaging)

Diagnosis:
- Legionella PCR detects ~100% of all Legionella species from lower respiratory secretions (3)[C].
- Urinary antigen test (UAT) detects serogroup 1 (which causes 80% of disease). UATs are highly specific (95–100%) but of variable sensitivity. Legionella culture (gold standard) requires an adequate sputum sample and special media (buffered charcoal yeast extract [BCYE] agar). Culture has variable sensitivity (10–80%) and time delays of up to 7 days for results (4)[C].
- Other lab abnormalities:
  - Hyponatremia
  - Hypophosphatemia (transient)
  - Lymphopenia
  - Mildly elevated serum transaminases; elevated LDH; elevated creatine kinase
  - Microscopic hematuria
  - Highly elevated C-reactive protein (CRP) (>30)
  - Highly elevated ferritin (≥2 times normal)
- Chest radiograph
  - Not specific for Legionella
  - Commonly shows unilateral lower lobe patchy alveolar infiltrate with consolidation
  - Cavitation and abscess formation are more common in immunocompromised patients.
  - Pleural effusion occurs in up to 50%.
  - May take 1 to 4 months for radiographic findings to resolve. Progression of infiltrate on x-ray can be seen despite antibiotic therapy.

Diagnostic Procedures/Other

Transtracheal aspiration/bronchoscopy occasionally necessary to obtain sputum/lung samples

Test Interpretation

- Multifocal pneumonia with alveolitis and bronchiolitis and fibrinous pleuritis; may have serous or serosanguineous pleural effusion
- Abscess formation occurs in up to 20% of patients.
- Progression of infiltrates on x-ray (despite appropriate therapy) suggests Legionnaires’.
  Radiographic improvement may not correlate with clinical findings (longer lag times).
- Use of procalcitonin levels of limited value as it is not as sensitive in atypical pathogens such as Legionella
GENERAL MEASURES

- Supportive care:
  - Oxygenation, hydration, and electrolyte balance with antibiotic therapy
- Extrapulmonary complications and higher mortality may be seen in patients with AIDS
- In severe pneumonia, obtain UAT and start empiric antibiotics to include coverage for Legionella (5)[C].

MEDICATION

First Line

- Antibiotics that achieve high intracellular concentrations (e.g., macrolides, tetracyclines, fluoroquinolones) are most effective; first-line treatment is levofloxacin; no prospective randomized controlled trials have compared fluoroquinolones to macrolides for the treatment of Legionella; levofloxacin associated with more rapid defervescence, fewer complications, decreased hospital stay by 3 days, and decreased mortality (4% vs. 10.9%) compared with macrolide antibiotics (5)[A]

- Start antibiotics parenterally if sufficiently ill due to the GI symptoms associated with Legionella:
  - Levofloxacin is the preferred agent:
    - Levofloxacin 750 mg/day IV (switch to PO when patient is afebrile/tolerating PO) for 5 days or 750 mg/day for 7 to 10 days
    - Azithromycin may also be used first line. It requires a shorter duration of treatment than levofloxacin due to a longer half-life:
      - Azithromycin 500 mg/day IV (switch to PO when afebrile/tolerating PO) for 7 to 10 days

Contraindications:
- Hypersensitivity reactions

Precautions:
- Liver disease

Significant drug interactions:
- Can increase theophylline, carbamazepine, and digoxin levels; can increase activity of oral anticoagulants
- May decrease the effectiveness of digoxin, quinidine, oral contraceptives, and hypoglycemic agents

- Longer courses of treatment (up to 21 days) may be needed in immunocompromised patients or valvular heart disease.

Second Line

- Doxycycline 100 mg IV/PO q12h for 14 days; for severe infections, initial dose is 200 mg IV/PO q12h.
  - Doxycycline should not be used in pregnant patients and is not approved for children <8 years.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inability to tolerate oral antibiotics
- Hypoxemia
- Criteria for direct admission to the ICU:
  - Any major criteria for severe CAP:
    - Septic shock requiring vasopressor support
• Acute respiratory failure requiring intubation and/or mechanical ventilation
  – Three or more minor criteria for severe CAP:
    • RR ≥30 breaths/min, PaO₂:FiO₂ ratio ≤250, multilobular infiltrates,
      confusion/disorientation, uremia (BUN ≥20 mg/dL), leukopenia (WBC <4,000
      cells/mm³), thrombocytopenia (PLT <100,000 cells/mm³), hypothermia (temperature
      <36°C [96.8°F]), hypotension requiring aggressive fluid resuscitation
• Discharge criteria
  – Afebrile
  – Able to tolerate oral antibiotics
  – Return to normal/baseline room-air oxygen saturation

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

• Monitor respiratory status, hydration, and electrolyte status closely.
• Chest radiography lags behind the clinical status and may not help with monitoring clinical
  response.

**PATIENT EDUCATION**

• Disease prevention: Eliminate pathogens from water supplies, low-emission cleaning of
  cooling towers with control measurements of water and air samples.
• Legionella is not spread person to person.

**PROGNOSIS**

• Improved prognosis when appropriate antibiotics are started early in the disease course
• Recovery is variable:
  – Patients may clinically worsen despite appropriate initial treatment (first 1 to 2 days of
    therapy).
  – Improvement with defervescence in 3 to 5 days and complete recovery in 6 to 10 days is
    typical. Some have a more protracted course.
• Mortality in nosocomial infections as high as 15–34%

**COMPLICATIONS**

• Dehydration
• Hyponatremia
• Respiratory insufficiency requiring ventilator support
• Bacteremia/lung abscess formation in up to 20%
• Extrapulmonary diseases:
  – Endocarditis (most common extrapulmonary site)
  – Cellulitis
  – Sinusitis
  – Pancreatitis
  – Pyelonephritis
  – Encephalitis
  – Pericarditis
– Perirectal abscess
● Renal failure
● Disseminated intravascular coagulation
● Multiple organ dysfunction syndrome (MODS)
● Coma
● Death occurs in 8–12% of treated immunocompetent patients and in up to 80% of untreated immunocompromised patients.

CODES
ICD10
● A48.1 Legionnaires’ disease
● A48.2 Nonpneumonic Legionnaires’ disease [Pontiac fever]
CLINICAL PEARLS

- Legionella is an intracellular organism that can only be grown on BCYE agar.
- Consider Legionnaires’ disease in patients with pneumonia who have GI and other extrapulmonary findings (atypical CAP) and a relative bradycardia. Relative lymphopenia, mildly elevated serum transaminases (aspartate aminotransferase/alanine aminotransferase), highly increased ferritin levels, or hypophosphatemia are other laboratory clues to Legionella infection.
- Serology is not useful in early stages of the disease (an increase in Legionella antibody titers cannot be detected until 3 to 4 weeks after symptom onset).
- UAT and Legionella sputum PCR are the most sensitive and practical initial tests. Sputum culture is definitive but can take up to 7 days.
- Consider Legionnaires’ disease in cases of nosocomial pneumonia.
LESBIAN HEALTH
Tina D’Amato, DO

BASICS

DESCRIPTION
- A lesbian is a woman who has her primary emotional and sexual relationships with women.
- Other sexual minorities include bisexual, transgender, and transsexual women.
- Sexual behaviors
  - May be celibate; sexually active only with women or with men, women and/or non-binary partners
  - ~75% of self-reported lesbians have reported prior or ongoing sexual contact with men.
- Sexual orientation and gender nonconformity are complex concepts, and defining them can be challenging.

EPIDEMIOLOGY

Prevalence
- Estimated to be between 1% and 5%
- Approximately 1.4 million women living in the United States identify as lesbians. Another 2.6 million women identify as bisexual.
  - 2017 Gallup Daily Tracking showed 5.1% of female respondents identified as LGBTQ.
- 2016 American Community Survey from United States Census Bureau estimates 451,594 households are headed by female same-sex couples.

RISK FACTORS

Higher incidence for the following risk factors compared to heterosexual women:
- Elevated BMI
  - Lesbian women have a higher prevalence of overweight/obesity than all other female sexual orientation groups.
- Alcohol use
  - More common use than reported in heterosexual women
  - Age 20 to 34 years is at highest risk for daily use and heavy use of alcohol. Those numbers decline in older age groups.
- Tobacco use
  - 2 times more likely to smoke than heterosexual women
  - Aggressive marketing by tobacco industry to LGBTQ individuals
- Sexual minority stress (1)
  - Increased risk for health issues secondary to greater exposure to social stresses related to prejudice and stigma
  - Many of the increased health risks in lesbians can be attributed to behaviors that are the result of dealing with the stress and stigma of homophobia and discrimination (2).
- The above factors can increase risks for
  - Cardiovascular disease (CVD)
  - Type 2 diabetes
  - Hepatic disease
- Cancers

**COMMONLY ASSOCIATED CONDITIONS**

- **Cervical cancer**
  - Lesbians are equally at risk for developing cervical cancer compared to heterosexual women.
  - HPV can be transmitted genitally skin to skin, oral to genitals, and digital to genitals.
  - Risk of cervical cancer is highest in lesbians:
    - With prior HPV infection/abnormal Pap smear
    - Who have had a history of heterosexual intercourse
  - Lesbian and bisexual women are 10 times less likely to have adequate cervical cancer screening compared to heterosexual women.
  - Tobacco use influences cervical cell atypia.

- **Breast cancer**
  - Risk factors same as heterosexual women
    - Moderate or heavy alcohol consumption
    - Obesity
    - Nulliparity or first child born after age 30 years
  - Mammogram screening rates lower among lesbians
  - Data suggest lesbians have increased mortality rate compared to heterosexual women (3).

- **Ovarian cancer**
  - Elevated BMI and tobacco use increases risk.
  - Lesbians less likely to have been on hormonal contraception for 5 years or longer
  - Lesbians less likely to have been pregnant or breastfed an infant before age 30 years
  - Lesbians at increased risk for ovarian cancer may want to explore potential benefits of long-term progestin-containing contraception to reduce risk.

- **CVD**
  - Lesbians have higher rates of obesity, smoking, and stress, which increase risks for CVD.

- **Mental health diagnoses**
  - 2 times more likely to see general physician for mental/emotional complaint
    - Depression
      - Double the rate compared to heterosexual women
      - Discrimination stress proposed factor
    - Anxiety disorders
      - 2- to 4-fold higher rate of generalized anxiety disorder
      - Higher rates of post-traumatic stress disorder (PTSD) panic, phobia
      - Multiple diagnoses
      - 3 times risk
    - Alcohol abuse
      - Greatest in lesbians ages 20 to 34 years
      - Bar culture
      - May not feel comfortable in traditional Alcoholics Anonymous environment
      - Sexual minority females more likely than heterosexual counterparts to be current alcohol users, binge drinkers, and heavy drinkers (4)

- **Sexually transmitted infections (STI)**
  - Many lesbians underestimate their STI risks.
  - Difficult to ascertain accurate statistics because of lack of research and the confounding
factors of relying on identifiers of sexual orientation versus sexual behaviors

- Lesbian sexual practices include the following:
  - High risk: oral–vaginal contact, genital–genital contact, oral–anal contact, digital stimulation/penetration, and sharing of sex toys
  - Lower risk: kissing, rubbing genitals against partner’s body

- Bacterial vaginosis
  - Higher rate than heterosexual women
    - Estimated 25–52% prevalence
  - Increased incidence with smoking, receptive oral sex, symptomatic partner, and new partner
  - Often found in monogamous lesbian couples suggesting it can be sexually transmitted

- Chlamydia
  - Can be transmitted woman to woman (WTW)

- Gonorrhea
  - Can be transmitted WTW

- Hepatitis B
  - Can be transmitted WTW

- Herpes
  - Can be transmitted WTW

- HPV
  - Can be transmitted WTW
  - Up to 30% of women who have sex with women (WSW) have genital HPV (5).
  - 12% of WSW report genital warts.
  - 25% of WSW report cervical abnormalities.
  - WSW may not get HPV vaccine due to perceived decreased risk.

- HIV
  - Transmission between women rare but possible
  - WSW more likely to have sexual contact with men having sex with men (MSM) than heterosexual women

- Syphilis
  - Can be transmitted WTW

- Trichomonas
  - Can be transmitted WTW

- STI screening and prevention
  - Screen based on woman’s history.
  - Encourage safer sex practices:
    - Avoid menstrual blood/open sores.
    - Dental dams for oral sex
    - Condoms on sex toys and cleaning immediately after use
    - Vinyl/latex gloves for manual sex

- Psychosocial considerations
  - Sexual abuse
    - 3 times more likely than heterosexual women to report having been sexually assaulted
    - 43% of lesbians reported at least one sexual assault in their lifetime.
    - History of childhood sexual abuse can be associated with more complicated and difficult “coming out.”
  - Intimate partner violence
17–45% of lesbians report at least one act of physical violence at the hands of a lesbian partner.

Parenthood
- A reported 41% of lesbians desire to have a child.
  - Perinatal depression is common and may be more common than in heterosexual women.
- >30% have biologic children.
  - Often from previous heterosexual relationship
  - Adoption
  - Assisted reproductive technology/donor insemination
  - Some will engage in high-risk sexual behaviors (MSM, “one-night stand”) in an attempt to get pregnant.
  - Providers should discuss parenting with their lesbian patients.
  - Encourage both partners or nonbiologic parent to adopt child to ensure permanent legal relationship to child.
  - Discuss durable power of attorney for health care and finances in the event of death or separation.
  - Adolescents who have been reared in lesbian mother families since birth demonstrate healthy psychological adjustment.

Adolescent lesbians
- Increased risk for eating disorders
- Higher rates of substance use, particularly polysubstance abuse
- If also having sexual contact with males, higher rates of pregnancy compared to heterosexual counterparts due to
  - High rates of early sexual initiation
  - Greater number of partners
  - Less contraceptive use
- Higher rates of physical and/or sexual abuse
  - Childhood sexual abuse does not cause children to become LGBTQ.

Aging lesbians
- Elders aging “back into the closet”
  - Discrimination by religious and other groups that own nursing homes
  - Fear of discrimination by caregivers/health care workers
  - Few elder care programs specifically directed at LGBTQ persons

TREATMENT

GENERAL MEASURES
- Create a safe practice environment for lesbian patients.
  - Have nondiscrimination policy posted where it is visible to patients.
  - Educate staff to be comfortable dealing with the needs of lesbian patients and their families.
  - Brochures/photos should feature both same-sex and heterosexual couples.
  - Intake forms should include options for patient to indicate sexual preference and include options for partnered status.
  - Use “gender-neutral” language.
    - “Do you have a significant other?”
– Avoid heterosexist assumptions (“What do you use for birth control?” asking instead “Do you plan to become pregnant or have a child? Do you need birth control?”).

- Ask about sexual orientation.
  - Many physicians do not ask.
  - Intake/annual physical forms should include questions about orientation/activity.
  - Twice as likely to identify as a sexual minority if questions asked in an indirect way

- Take a detailed sexual history.
  - Sexual identity and sexual behaviors not always strongly correlated
  - Ask about behaviors (“Do you have sex with women, men, or both?”); do not just assume current/past sexual activity with women.
  - STI screening based on reported history/activity
  - Address contraception when appropriate.
  - Some physicians may create barriers by believing a patient’s sexual self-identity and behaviors are not pertinent to competent care (7).

- Respect the partners.
  - Treat her as you would any other spouse/partner.
  - Ensure access if partner hospitalized.
  - Recommend durable power of attorney if couple is not legally married.

- Follow same preventive screening guidelines and lifestyle recommendations as for heterosexual women (Pap smear, mammography, colonoscopy screening, safer sex, exercise, diet, alcohol moderation, and tobacco avoidance).

- Legal/U.S. government
  - Healthy People 2010 identified lesbian/gay Americans as 1 of 6 population groups affected by health care disparities.
  - Healthy People 2020 goals to increase routine data collection efforts on LGBTQ populations via health care surveys
  - Access to health insurance was increased with Supreme Court decisions on United States v. Windsor in 2013 and Obergefell v. Hodges in 2015.
  - Some states still recognize same-sex civil union, but access to health insurance varies by state.
  - Affordable Care Act (ACA)
    - Prohibits discrimination based on sexual orientation in any program receiving federal funds (Medicare/Medicaid)
    - Increased emphasis on research and data collections in LGBTQ population
      - National Health Interview Survey (NHIS)
        - 2013 survey added a question about sexual orientation.
        - This was the first time nationally representative U.S. data on sexual orientation and health were made available.

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**
- E66.3 Overweight
- Z72.0 Tobacco use
- F10.10 Alcohol abuse, uncomplicated

**CLINICAL PEARLS**
- Create a safe health care environment for all patients.
- Use gender-neutral language.
- Do not assume heterosexuality or sexual practices.
- Take a detailed history and avoid assumptions.
- Be aware that some patients may openly identify as lesbian, but others may only identify when asked directly. Some may be engaging in a same-sex relationship and not identify as a lesbian.
- Follow same preventive screening guidelines and lifestyle recommendations as for heterosexual women.
- Discuss durable power of attorney for health care needs to ensure partner’s involvement in care.
LEUKEMIA, ACUTE LYMPHOBLASTIC (ALL) IN ADULTS
Katyayini Aribindi, MD • Adrian DaSilva-DeAbreu, MD • Mark A. Farnie, MD

**BASICS**

**DESCRIPTION**
- Acute lymphoblastic leukemia (ALL) in adults is the result of a clonal proliferation, survival, and impaired differentiation of immature lymphocytes. The World Health Organization (WHO) defines ALL as the presence of ≥25% lymphoblasts in the bone marrow (1), whereas the National Comprehensive Cancer Network (NCCN) uses a ≥20% as cutoff (2).
- ALL and lymphoblastic lymphoma (LBL) can arise from the same precursor cell line, and therefore can be considered diseases along the same spectrum:
  - LBL presents as a mass, possibly, but not limited to, the mediastinum, with <25% blasts in the bone marrow.
  - ALL may present with a mass lesion but contains ≥25% bone marrow involvement.
- Any organ can be affected.

**Pregnancy Considerations**
Many chemotherapy (CTX) drugs are teratogenic.

**Pediatric Considerations**
ALL is the most common malignancy in children—it accounts for 30% of all pediatric malignancies and 80% of pediatric leukemias (see “Acute Lymphoblastic Leukemia, Pediatric”).

**Geriatric Considerations**
Patients >60 years with ALL have a 42% mortality during induction CTX. The cause of death is usually CTX-related complications or relapse. Survival is often reduced due to poor tolerance of CTX, thus leading to dose reductions and ineffective medication delivery.

**EPIDEMIOLOGY**
- Incidence of ALL is 1.7/100,000 per year.
- Higher incidence in males, whites, those with history of radiation, CTX, or certain genetic disorders
- Bimodal distribution: early peak at 4 to 5 years of age, second peak at ~50 years
- 80% of cases occur in children, 20% in adults.

**ETIOLOGY AND PATHOPHYSIOLOGY**
Unknown in most patients

**Genetics**
- Higher rates in monozygotic and dizygotic twins
- Increased risk of ALL with diseases related to chromosomal instability: Bloom syndrome, Fanconi anemia, ataxia-telangiectasia, neurofibromatosis
- Increased risk with inherited chromosomal abnormalities: Down syndrome, Klinefelter syndrome, etc.

---

RISK FACTORS
- Age >70 years, radiation exposure, and infection with HIV are risk factors for developing ALL.
- Human T-cell lymphotropic virus type 1 is associated with adult T-cell ALL.
- Epstein-Barr virus is associated with mature B-cell ALL.

DIAGNOSIS

HISTORY
- Symptoms arise from sequelae of bone marrow suppression and/or from leukemic cell organ infiltration.
- B symptoms: fever, weight loss, night sweats
- Anemia: fatigue, shortness of breath, light-headedness, angina, headache
- Thrombocytopenia: easy bruising
- Neutropenia: fever, infection
- Lymphocytosis: bone pain
- CNS: confusion
- Organ infiltration: organ-specific symptoms and signs

PHYSICAL EXAM
- Thrombocytopenia: petechiae, ecchymoses, epistaxis, retinal hemorrhages
- Anemia: pallor
- Neutropenia: fever, infections
- Lymphocytosis: lymphadenopathy; splenomegaly; less often, hepatomegaly
- CNS: cranial nerve palsies, meningeal signs
- Testicular invasion: abnormal testicular exam

DIFFERENTIAL DIAGNOSIS
- Malignant disorders: other leukemias, especially AML, chronic myeloid leukemia in lymphoid blast phase, prolymphocytic leukemia, malignant lymphomas; multiple myeloma, bone marrow metastases from solid tumors (breast, prostate, lung, renal), and myelodysplastic syndromes
- Nonmalignant disorders: aplastic anemia, myelofibrosis, autoimmune diseases (Felty syndrome, lupus), infectious mononucleosis, pertussis, autoimmune thrombocytopenic purpura, leukemoid reaction to infection

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- CBC with differential:
  - Anemia: normocytic, normochromic
  - Thrombocytopenia
  - Peripheral blood lymphoblasts (B cell or T cell)
- Hepatitis B/C, HIV, CMV Ab testing, LDH
- Pregnancy test if indicated
- Tumor lysis panel: uric acid, potassium, calcium, phosphorus

See “Follow-Up Tests & Special Considerations.”
CT of the neck, chest, abdomen, and pelvis with contrast and PET/CT if suspicion of lymphomatous involvement
CT/MRI of head with contrast if neurologic symptoms are present
Scrotal US if abnormal testicular exam

Follow-Up Tests & Special Considerations

- Immunophenotyping of marrow/blood lymphoblasts: B lineage (CD19, CD20, CD22, CD24), T lineage (CD2, CD3, CD5, CD7), common ALL antigen (CD10); human leukocyte antigen (HLA)-DR, terminal deoxynucleotidyl transferase (TdT), aberrant myeloid antigens (CD13, CD33), and stem cell antigen (CD34)
- Cytochemical stains: myeloperoxidase negative; Sudan black B usually negative; TdT positive; periodic acid–Schiff ± is variable, depending on subtype.
- Cytogenetics: Specific recurring chromosomal abnormalities have independent diagnostic and prognostic significance (hyperdiploidy >50 chromosomes or t[14q11q13] are favorable; the Philadelphia [Ph] chromosome, t[9;22], t[4;11], −7, and +8 are unfavorable). A translocation t(8;14) or t(2;8) or t(8;22) identifies Burkitt-type mature B-cell leukemia that requires specific therapy.
- Reverse transcription polymerase chain reaction for rapid diagnosis of BCR/ABL1+ ALL
- Genomic analysis by next-generation sequencing: detection of mutations associated with Ph-like ALL
- HLA typing of patient and siblings for hematopoietic stem cell transplantation

Diagnostic Procedures/Other

- Bone marrow aspiration/biopsy with immunohistochemistry, immunophenotyping, cytogenetics, and molecular diagnostics
- Lymph node biopsy if available
- Lumbar puncture is mandatory and typically done both for diagnosis of CNS involvement and for intrathecal (IT) CTX. It should be done at diagnosis and immediately if neurologic symptoms or signs are present. Repeat lumbar puncture after bone marrow remission is achieved to evaluate occult CNS involvement and continue prophylactic CNS treatment.

Test Interpretation

Diagnosis of ALL is generally based on the presence of ≥20% (NCCN definition) (2) or ≥25% (WHO definition) (1) lymphoblasts in the bone marrow. In some cases, the diagnosis of ALL can be made based on the presence of certain mutations (1), even if the percentage of blasts is lower than these numbers. The bone marrow biopsy typically shows diffuse replacement of marrow and lymph node architecture by sheets of malignant lymphoblasts, T-cell or B-cell lineage determined by CD expression.

TREATMENT

GENERAL MEASURES

- Three phases to treatment:
  - Induction + CNS prophylaxis
  - Consolidation
  - Prolonged maintenance
- Treatment for initial induction and relapse is changing based on Ph receptor status and should
be managed by a specialist.

Hyperleukocytosis with WBC >50,000 or 100,000 can lead to leukostasis, a medical emergency with microvascular white cell plugs. Patients may present with neurologic deficits or respiratory distress and should be treated with fluids, and cytoreductive therapy (hydroxyurea, plasmapheresis, or remission induction CTX).

MEDICATION

Induction

- The mainstay of treatment is a regimen called hyper-CVAD (3)[A]: hyperfractionated cyclophosphamide, vincristine, anthracyclines, and dexamethasone. Hyper-CVAD is the most widely used regimen for ALL in adolescents and young adults.
- Hyper-CVAD consists of eight alternating treatment cycles of parts A and B:
  - Part A: Hyper-CVAD
  - Part B: high-dose methotrexate and cytarabine
  - Granulocyte colony-stimulating factors are given after each cycle to prevent delay in treatment and hasten bone marrow recovery (4)[A].
  - CNS prophylaxis: IT CTX consistent of IT- methotrexate or cytarabine or 6-mercaptopurine (6-MP) throughout all three phases (2)[A]
  - Those with CNS leukemia at diagnosis will need twice a week IT therapy until CSF is cleared on three subsequent lumbar punctures (2)[A].
- <40 years of age with complete remission after the first induction, the next step is either consolidation CTX or allogeneic stem cell transplant based on risk donor availability.
- Minimal residual disease (MRD), measured by flow cytometry in the US, signifies CTX refractory disease, usually in 8 months from start of treatment with continued CTX. These patients should be evaluated for an allogeneic bone marrow transplant (2)[A].

Consolidation

- Purpose is to eliminate residual leukemic cells after induction therapy.
- Induction phase drugs are used.
- Peg-asparaginase is used in children but has poorer outcomes and toxicities in adults (5)[A].

Prolonged maintenance

- Purpose is to prevent relapse and prolong remission.
- Consist of POMP: daily 6-MP, weekly methotrexate, monthly vincristine, with pulses of prednisone for 2 to 3 years. Little benefit has been shown for >3 years of prolonged maintenance (3,6)[A].
- Dexamethasone can be substituted for prednisone, a.k.a DOMP.

Special considerations

- Besides hyper-CVAD, some pediatric ALL regimens have shown superior complete remission outcomes for adults from 15 to 39 years. These usually contain vincristine and peg-asparaginase, nonmyelosuppressive agents.
- Allogeneic stem cell transplantation is also recommended with relapsed ALL during the first remission or if there are high-risk genetic features.
- Burkitt leukemia requires only 18 weeks of treatment and has better outcomes with methotrexate and alkylating agents in the initial therapy. Rituximab (anti-CD20 monoclonal antibody) also improves outcomes.
- Rituximab improves outcomes if CD20 expression is >20% of blast cells in ALL.
- Immunotherapy:
  - Bispecific anti-CD19/anti-CD3 antibody blinatumomab is approved for
relapsed/refractory ALL.
- Ofatumumab is a 2nd-generation anti-CD20 monoclonal antibody undergoing trials with concomitant hyper-CVAD in pre-B-cell ALL with CD20 expression >1%.
- Ph-positive ALL have improved prognosis with tyrosine kinase inhibitors (TKIs) targeting BCR-ABL1 translocation. Consolidation/maintenance with a TKI may be used instead of allogeneic stem cell transplant in these patients.
- Adult T-cell ALL is much less common than B-cell ALL and unfortunately has a relapse rate up to 50% with traditional hyper-CVAD therapy. Nelarabine is a T cell–specific purine nucleoside and currently is approved for relapsed T-cell ALL, with additional clinical trials studying a combination of hyper-CVAD and nelarabine as part of induction therapy.
- Patients with unfavorable cytogenetic subtypes should undergo allogeneic stem cell transplantation on first remission if an HLA-identical donor is available.
- A novel agent, inotuzumab-ozogamicin combination, has shown higher rates of complete remission and longer progression free and overall survival in patients with relapsed or refractory ALL when compared to standard therapy (7)[A].

ISSUES FOR REFERRAL
ALL can quickly become a fatal disorder, and thus, when the diagnosis is suspected, patients should be referred to and treated by an oncologist immediately, preferably at a comprehensive cancer center where medication regimen can be tailored as appropriate with a combination of multiple modalities.

SURGERY/OTHER PROCEDURES
In some centers, patients may undergo surgical placement of a port for CTX. Nevertheless, PICC lines are preferred because they can be easily removed after CTX cycles to decrease the risk of infections. This is very important because these patients can get neutropenic.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Unproven; may result in adverse drug interactions with CTX

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Ambulatory as tolerated

Patient Monitoring
- Requires inpatient admission during induction CTX for continuous infusion and monitoring of metabolic and infectious complications
- Weekly clinic visits with remission consolidation CTX
- Monthly clinic visits during maintenance therapy
- Outpatient follow-up every 3 months thereafter

DIET
- Nutritional support; enteral nutrition is preferred over IV hyperalimentation.
- Avoid alcohol.
- Calcium and vitamin D for steroid-induced osteoporosis
PATIENT EDUCATION

- Neutropenic precautions with avoidance of fresh fruit and vegetables
- Early physical rehabilitation is always recommended due to high risk of deconditioning.
- All patients should be counseled to stop smoking, regardless of ALL diagnosis.

PROGNOSIS

~80–90% of adults <60 years will achieve a complete remission; however, only 40–50% will remain cured due to relapses. Only 30–40% of adults have a 5-year overall survival as opposed to 90% in children.

COMPLICATIONS

- Tumor lysis syndrome (elevated uric acid, potassium, and phosphate with decreased calcium, leading to renal failure, disseminated intravascular coagulation, and cardiac arrhythmias) may be prevented by administering allopurinol prior to CTX. Allopurinol doses should be reduced if used with mercaptopurine or azathioprine. Increased fluids should be given; IV urate oxidase (rasburicase) can be used to treat hyperuricemia rapidly (if not G6PD deficient).
- Neutropenia from myelosuppression
- High-dose cyclophosphamide causes severe nausea and vomiting. Use appropriate antiemetic regimen.
- Vincristine can cause neurotoxicity and ileus.
- AVN or osteonecrosis may occur with alkylating agents and corticosteroids.
- Steroid-induced hyperglycemia may require starting patients on insulin/oral antihyperglycemics.
- Anthracyclines can cause cardiotoxicity and require assessment of left ventricular ejection fraction by transthoracic echocardiography before hyper-CVAD initiation begins and monitoring during treatment.
- Asparaginase therapy increases the risks for deep vein thromboses and veno-occlusive disease.
- Infections (Pneumocystis carinii pneumonia, bacterial pneumonia or sepsis, fungal pneumonia)
- Adverse reactions from blood product transfusions for pancytopenia
- CTX can cause sterility.
- Arachnoiditis and CNS effects from IT CTX, high-dose methotrexate, and irradiation
- Pancreatitis and liver dysfunction from CTX
- Relapse of ALL in marrow or extramedullary sites (CNS, testis)

REFERENCES

CODES

ICD10
● C91.00 Acute lymphoblastic leukemia not having achieved remission
● C91.01 Acute lymphoblastic leukemia, in remission
● C91.02 Acute lymphoblastic leukemia, in relapse

CLINICAL PEARLS

● The diagnosis of ALL is based on the presence of ≥20% (NCCN) or 25% (WHO) lymphoblasts or characteristic mutations in the bone marrow.
● Hyper-CVAD is still the main therapy; however, newer immunotherapeutic agents targeting specific mutations in ALL are currently being investigated.
● Treatment at an appropriate cancer center allows for tailored therapy based on mutations in ALL cells.
● Patients need to be monitored closely for CTX toxicities and progression of disease.
LEUKEMIA, ACUTE MYELOID
Jan Cerny, MD, PhD

BASICS

DESCRIPTION
- Acute myeloid leukemia (AML) is characterized by proliferation and accumulation of abnormal immature myeloid progenitors (blasts) with reduced capacity to differentiate into more mature cellular elements. This leads to bone marrow failure and results in a variety of systemic symptoms.
- Previously, the French–American–British (FAB) classification system divided AML based on the cell morphology with the addition of cytogenetics (subtypes M0 to M7).
- The World Health Organization (WHO) classification attempts to provide more meaningful prognostic information.
  - AML with characteristic genetic abnormalities: translocation t(8;21), t(15;17), and inversion in chromosome 16 inv(16)
  - AML with multilineage dysplasia: presence of a prior myelodysplastic syndrome (MDS) or myeloproliferative neoplasm (MPN) that transformed into AML
  - AML and MDS, therapy related
  - AML not otherwise categorized
  - Acute leukemias of ambiguous lineage (biphenotypic acute leukemia)

EPIDEMIOLOGY
- ~19,950 cases estimated in 2016 making it the most common type of leukemia in adults
- Predominant sex: male > female

Incidence
The incidence of AML increases with age, and median age is 67 years.

ETIOLOGY AND PATHOPHYSIOLOGY
Precise causes unknown, but some risk factors have been identified (see “Risk Factors”)

Genetics
- Unknown; some are familial.
- Cytogenetics and genetics play an important role in diagnosis and prognosis of AML and have implications for therapy.
  - Three risk groups
    - Good risk: inv(16), t(8;21), t(15;17)
    - Standard risk: normal karyotype
    - Poor risk: monosomy 5 and 7 (typically secondary AML), deletion 5q, abnormalities of 11q23 or complex karyotype
  - FLT3 gene mutations, especially internal tandem duplications (FLT3-ITD), have been associated with poor survival in AML. These and growing list of (onco)gene (e.g., NPM1, DNMT3A, and P53) mutations have been studied to further risk-stratify patients (1,2)[A].

RISK FACTORS
Genetic predisposition (e.g., Down syndrome); other familial disorders are Bloom syndrome (~25% develop AML), Fanconi anemia (52%), neurofibromatosis, Li-Fraumeni syndrome, Wiskott-Aldrich syndrome, Kostmann syndrome, and Diamond-Blackfan anemia.

- Radiation exposure
- Immunodeficiency states
- Chemical and drug exposure (nitrogen mustard and alkylating agents; benzene)
- MDS
- Cigarette smoking

**GENERAL PREVENTION**
None currently identified, but treatment of high-risk MDS with demethylating agents (5-azacitidine [Vidaza]) has been shown to prolong time to transformation from MDS into AML (3 [A]).

**COMMONLY ASSOCIATED CONDITIONS**
The following are oncologic emergencies:
- Disseminated intravascular coagulopathy (DIC) especially in acute promyelocytic leukemia (APL) but may be seen in any AML
- Leukostasis (high blast number and increased adhesive ability of blasts)
- Tumor lysis syndrome (TLS): spontaneous or in response to chemotherapy

**DIAGNOSIS**

**HISTORY**
Fatigue (anemia or tumor burden); bleeding (low platelets or DIC); difficulty clearing infections (neutropenia or immune dysregulation)

**PHYSICAL EXAM**
- Mostly nonspecific and related to marrow or tissue infiltration
  - Fever
  - Bleeding
  - Pallor
  - Splenomegaly
  - Hepatosplenomegaly
  - Lymphadenopathy (usually reactive)
- If central nervous system is involved, symptoms of increased intracranial pressure can be present.
- Occasionally, patients will present with prominent extramedullary sites of leukemia (e.g., skin infiltration or ultimately as a myeloid sarcoma).

**DIFFERENTIAL DIAGNOSIS**
- Virus-induced cytopenia, lymphadenopathy, and organomegaly
- Immune cytopenias (including systemic lupus erythematosus [SLE])
- Drug-induced cytopenias
- Other marrow failure and infiltrative diseases (e.g., aplastic anemia, paroxysmal nocturnal hemoglobinuria, MDS, Gaucher disease)
DIAGNOSTIC TESTS & INTERPRETATION

- Complete blood count (CBC) shows subnormal red blood cells (RBCs), neutrophils, and platelets.
- Bone marrow for histology, flow cytometry, and cytogenetics to establish diagnosis and prognosis
- Erythrocyte sedimentation rate
- Lactate dehydrogenase (LDH) and uric acid can be elevated (e.g., TLS).
- Coagulation profile can be normal or prolonged (e.g., DIC).
- Drugs that may alter lab results: chemotherapy agents, corticosteroids
- Other special tests: Spinal tap may reveal fluid with leukemic cells.
- Ultrasonography or CT scan of the abdomen may discover organomegaly.

Diagnostic Procedures/Other

Bone marrow studies are usually necessary to make the diagnosis.
- Aspirates: for cell morphology, cytochemistries, immunophenotyping (can confirm differentiation stage of AML); cytogenetics: chromosomal aberration (prognostic value; see “Genetics”)
- Biopsies provide valuable information for cellularity, architecture, and so forth.

Test Interpretation

- Marrow is usually hypercellular and the normal architecture effaced; leukemic blast count is 20% or more.
- Liver and spleen may be infiltrated with leukemic cells.

TREATMENT

- Chemotherapy is the backbone of AML therapy; it consists of induction and consolidation phase ± maintenance (APL).
- Bone marrow transplantation (BMT) for high-risk AML
- Only modest improvements have been made in AML induction chemotherapy. Supportive care has improved significantly.

GENERAL MEASURES

- Ongoing assessment of bone marrow, liver, heart, and kidney functions during therapy
- Close monitoring of coagulation parameters (risk for DIC)
- Supportive therapy with
  - Good hydration
  - Transfusions of packed RBCs and platelets based on patient’s needs (threshold for platelets as low as 5,000); use leukoreduced, irradiated blood products because all patients can be considered for BMT.
  - Avoid antiplatelet agents (e.g., aspirin products).
  - Follow febrile neutropenic guidelines in neutropenic patient who becomes febrile (even low-grade fever).

Geriatric Considerations

- Older patients (>60 to 65 years of age) remain a therapeutic challenge. These patients are offered so-called reduced-intensity or nonmyeloablative BMT.
• Adding growth factors (granulocyte colony-stimulating factor [G-CSF]) may reduce toxicity in older patients (but is not broadly accepted).
• Hypomethylating agent, such as 5-azacitidine, significantly prolongs survival in older adults with low marrow blast count (<30%).

**Pediatric Considerations**
Tolerate intense treatments better

**Pregnancy Considerations**
Chemotherapy is a viable option in the 2nd and 3rd trimesters.

**MEDICATION**

**First Line**
• APL (APL, AML with t[15;17])
  – All-trans retinoic acid (ATRA) and arsenic trioxide both promote maturation to granulocytes. Their combination can be used in low and intermediate risk APL for (chemotherapy) free treatment.
  – Idarubicin is often added to induction therapy, in high risk group.
  – Monoclonal anti-CD33 (Mylotarg) is being added as well in order to minimize chemotherapy use in this curable leukemia.
• Treatment of AML in younger adults: AML (other than APL)
  – Induction (daunorubicin or idarubicin [anthracycline and cytarabine]): The generally accepted combination is 3 + 7 (anthracycline is given for 3 days and cytarabine for 7 days) or more intensive regimens with high-dose cytarabine (HiDAC) or high dose of anthracycline.
  – Liposomal preparation of daunorubicin and cytarabine (Vyxeos) is now available for AML with MDS changes or therapy-related AML.
• Remission is typically consolidated in younger patients by the following:
  – In good-risk AML, 3 to 4 cycles of HiDAC and BMT is reserved for time of recurrence.
  – In poor-risk patients, 1 to 2 cycles of HiDAC (until donor is identified) are followed by allogeneic BMT.
  – Intermediate-risk AML should be treated based on individual patient’s features, donor availability, and access to clinical trials. A meta-analysis showed that even intermediate-risk patients benefit from allogeneic BMT (4)[A].
• Treatment of AML in older adults (>65 years of age) remains a challenge. These patients have poor performance status, more likely secondary AML, higher incidence of unfavorable cytogenetics, comorbidities, shorter remissions, and shorter overall survival.
  – Intensive chemotherapy may be feasible for patients with good performance status; alternative regimens with mitoxantrone, fludarabine, and clofarabine.
  – Newly diagnosed patients who are 75 years or older or who have conditions that preclude them from receiving intense induction therapy have following options of novel (targeted) agents:
    o low dose cytarabine with glasdegib (DAURISMO, Pfizer Labs)
    o hypomethylating agents (azacytidine, Vidaza; decitabine; Dacogen) with ivosidenib (Tibsovo; IDH1 inhibitor)
    o hypomethylating agents (azacytidine, Vidaza; decitabine; Dacogen) with venetoclax (Venclexta; BCL-2 inhibitor)
FLT-3 inhibitors such as midostaurin (Rydapt) are approved as addition to induction and consolidation chemotherapy and gilteritinib (Xospata) is approved for relapsed/refractory AML.

Ivosidenib (Tibsovo; IDH1 inhibitor) and enasidenib (Idhifa; IDH2 inhibitor) are approved for relapsed/refractory AML.

Contraindications: comorbidities; therapy has to be individualized.

Precautions
– If organ failure, some drugs may be avoided or dose reduced (e.g., no anthracyclines in patients with preexisting cardiac problems).
– Patients will be immunosuppressed during treatment. Avoid live vaccines. Administer varicella-zoster or measles immunoglobulin as soon as exposure of patient occurs.

Significant possible interactions: Allopurinol accentuates the toxicity of 6-mercaptopurine.

Novel targeted therapies: midostaurin for AML with FLT3 mutations (both ITD and TKD). Ivosidenib (IDH1 inhibitor) and enasidenib (IDH2 inhibitor) for relapsed/refractory AML with respective IDH mutations; gemtuzumab ozogamicin (anti-CD33 monoclonal antibody) for relapsed/refractory AML with CD33 expression.

Second Line
Healthy, younger patients usually are offered reinduction chemotherapy and allogeneic BMT.

ISSUES FOR REFERRAL
– AML should be managed by specialized team led by a hematologist/oncologist.
– Refer patient to a transplant center early because a search for a donor may be necessary.

SURGERY/OTHER PROCEDURES
– BMT: Decision between myeloablative and nonmyeloablative approach should be based on patient’s performance status, comorbidities, and AML risk factors.
  – Allogeneic BMT is usually indicated in first remission in intermediate- or high-risk AML or in second remission in all other AML patients. Matched related donor used to be preferred over matched unrelated donor (lower risk of graft versus host disease); recent data suggest equal outcomes because allogeneic transplant regimens and posttransplant care have improved significantly.
– Haploidentical transplants and cord blood have emerged as alternative sources of hematopoietic stem cells for adults that show comparable outcomes as well.
– Autologous BMT may be acceptable in specific situations (e.g., no donor is available).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
– Induction treatment for AML requires inpatient care, usually on a specialized ward. Episodes of febrile neutropenia typically require admission and IV antibiotics.
– Appropriate hydration to prevent TLS
– IV may lead to chemical burns in the event of extravasation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Ambulatory, as tolerated; no intense or contact sports; no aspirin due to risk of bleeding.
**Patient Monitoring**
- Repeat bone marrow studies to document remission and also if a relapse is suspected.
- Follow CBC with differential, coagulation studies, uric acid level, and other chemistries related to TLS (creatinine, potassium, phosphate, calcium); monitor urinary function at least daily during induction phase and less frequently later.
- Physical evaluation, including weight and BP, should be done frequently during treatment.

**Diet**
Ensure adequately balanced calorie/vitamin intake; total parenteral nutrition (TPN) in case of severe mucositis

**Patient Education**
- Leukemia Society of America, 600 Third Avenue, New York, NY 10016, 212-573-8484
- National Cancer Institute, Bethesda, MD, has pamphlets and telephone education.

**Prognosis**
AML remission rate is 60–80%, with only 20–40% long-term survival. The wide variable prognosis is due to prognostic group (age, cytogenetics, and genetics).

**Complications**
- Acute side effects of chemotherapy, including febrile neutropenia
- TLS
- DIC
- Late-onset cardiomyopathy in patients treated with anthracyclines
- Chronic side effects of chemotherapy (secondary malignancies)
- Graft versus host disease in patients who have received allogeneic BMT

**References**

CODES
ICD10
- C92.00 Acute myeloblastic leukemia, not having achieved remission
- C92.01 Acute myeloblastic leukemia, in remission
- C92.02 Acute myeloblastic leukemia, in relapse

CLINICAL PEARLS
- AML is a proliferation and accumulation of abnormal immature myeloid progenitors (blasts) with reduced capacity to differentiate into more mature cellular elements. This leads to bone marrow failure and results in a variety of systemic symptoms.
- AML is most common leukemia in adults.
- Prognosis of leukemia depends on the cytogenetic and molecular profile of the disease.
- Allogeneic transplant remains the only therapy with curative potential for patients with intermediate- and high-risk AML.
LEUKEMIA, CHRONIC LYMPHOCYTIC
Jan Cerny, MD, PhD ● Ming-Jin Wang, DO

**BASICS**

**DESCRIPTION**
- Chronic lymphocytic leukemia (CLL) is a monoclonal disorder characterized by a progressive accumulation of mature but functionally incompetent lymphocytes.
- CLL should be distinguished from prolymphocytic leukemia (PLL); based on percentage of prolymphocytes, the disease may be regarded as CLL (<10% prolymphocytes), PLL (>55% prolymphocytes), or CLL/PLL (>10% and <55% prolymphocytes).
- Small lymphocytic lymphoma is a lymphoma variant of CLL.
- System(s) affected: hematologic, lymphatic, immunologic

**EPIDEMIOLOGY**

**Incidence**
- CLL represents the most common form of leukemia in adults in the United States with an estimated 20,720 new cases diagnosed in 2019 (1)[A].
- In 2019, an estimated 3,930 adults in the United States died from CLL, which makes it the second leading cause of death among adults with leukemia in the United States after acute myeloid leukemia (1)[A].
- Predominant age: CLL primarily affects elderly individuals, median age of diagnosis being 70 years. Incidence continues to rise in those age >55 years.
- Predominant sex: male > female (1.7:1)
- The incidence is higher among Caucasians than among African Americans.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- The cell of origin in CLL is a clonal B cell arrested in the B-cell differentiation pathway, intermediate between pre–B cells and mature B cells. In the peripheral blood, these cells resemble mature lymphocytes and typically show B-cell surface antigens: CD19, CD20, CD21, and CD23. In addition, they express CD5 (usually found on T cells).
- The bcl2 proto-oncogene is overexpressed in B-CLL. Bcl2 is a known suppressor of apoptosis (programmed cell death), resulting in extremely long life of the affected lymphocytes.
- Genetic mutations leading to disrupted function and prolonged survival of affected lymphocytes are suspected but unknown.

**Genetics**
- CLL is an acquired disorder, and reports of truly familial cases are exceedingly rare. CLL has been shown, however, to occur at higher frequency among first-degree relatives of patients with the disease, and several somatic gene mutations have been identified at significantly higher rates among CLL patients.

**RISK FACTORS**
- As in the case of most malignancies, the exact cause of CLL is uncertain.
- Possible chronic immune stimulation is suspected but is still being evaluated.
- Monoclonal B-cell lymphocytosis: 1% risk progression to CLL
GENERAL PREVENTION
Unknown

COMMONLY ASSOCIATED CONDITIONS
- Immune system dysregulation is common.
- Conditions that may accompany CLL:
  - Autoimmune hemolytic anemia (AIHA)
  - Immune thrombocytopenia purpura (ITP)
  - Pure red cell aplasia (PRCA)

DIAGNOSIS

HISTORY
- Insidious onset. It is not unusual for CLL to be discovered incidentally (up to 40% of patients are asymptomatic at the time of diagnosis).
- Others may have the following symptoms:
  - B symptoms: fevers, night sweats, >10% weight loss
  - Fatigue and/or other symptoms of anemia
  - Enlarged lymph nodes (lymphadenopathy = LAD)
  - Mucocutaneous bleeding and/or petechiae
  - Early satiety and/or abdominal discomfort related to an enlarged spleen
  - Recurrent infection(s)

PHYSICAL EXAM
- Lymphadenopathy (localized or generalized)
- Organomegaly (splenomegaly, hepatomegaly)
- Mucocutaneous bleeding (thrombocytopenia)
- Skin: petechiae (thrombocytopenia), pallor (anemia), rash (leukemia cutis)

DIFFERENTIAL DIAGNOSIS
- Infectious:
  - Bacterial (tuberculosis, pertussis)
  - Viral (mononucleosis)
- Neoplastic:
  - Leukemic phase of non-Hodgkin lymphomas
  - Hairy cell leukemia
  - PLL
  - Large granular lymphocytic leukemia
  - Waldenström macroglobulinemia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Complete blood count (CBC) with differential: B cell absolute lymphocytosis with >5,000 B lymphocytes/μL; often also shows anemia and/or thrombocytopenia
- Blood smear: ruptured lymphocytes (“smudge” cells) and morphologically small mature-appearing lymphocytes
- Confirm diagnosis with immunophenotyping: CLL cells are positive for CD19, CD20, CD23,
and CD5; low levels of surface membrane immunoglobulin (Ig)—either IgM or IgM&D; only a single Ig light chain is expressed (κ or λ) confirming monoclonality.

- Additional labs:
  - Hemolysis labs (in cases associated with high disease activity or AIHA): high lactate dehydrogenase (LDH) and indirect bilirubin, low haptoglobin, +/- elevated reticulocyte count (bone marrow infiltration)
  - High plasma β2-microglobulin (poor prognosis)
  - Hypogammaglobulinemia
- Liver/spleen ultrasound: may demonstrate organomegaly and enlarged abdominal lymph nodes
- CT scan of chest/abdomen/pelvis: not necessary for staging but may identify compression of organs or internal structures from enlarged lymph nodes
- Positron emission tomography (PET) scan: not recommended unless Richter transformation suspected and biopsy necessary (see “Prognosis”)

**Follow-Up Tests & Special Considerations**
Frequency and type of follow-up depend on severity of symptoms as well as risk factors (see “Prognosis”).

**Diagnostic Procedures/Other**
- Bone marrow biopsy: has prognostic value (diffuse infiltration is a risk factor) but not performed routinely
- Lymph node biopsy: Consider if lymph node(s) begins to rapidly enlarge in a patient with known CLL to assess the possibility of transformation to a high-grade lymphoma (Richter syndrome), especially when accompanied by fever, weight loss, and painful lymphadenopathy.

**Test Interpretation**
- Bone marrow biopsy aspirate usually shows >30% lymphocytes.
- Cytogenetics (fluorescence in situ hybridization) may show chromosomal changes, which are prognostic:
  - Unfavorable: del(17p), del(11q), TP53 mutation
  - Neutral: normal, trisomy 12
  - Favorable: del(13q), del(6q)

**TREATMENT**

**GENERAL MEASURES**
- Patients with CLL with frequent infections associated with hypogammaglobulinemia are likely to benefit from infusions of intravenous immunoglobulin (IVIG).
- Genetic risk stratification
  - Very high-risk disease: del (17p) and/or TP53 mutations
  - High-risk disease: IGHV unmutated (without 17p del or TP53 mutation)
  - Standard risk disease: IGHV mutated (without 17p del or TP53 mutation)

**MEDICATION**

**First Line**
- Standard of care for new diagnosis with no symptoms or early stage disease: observation
Standard of care for new diagnosis with symptoms (B symptoms, symptomatic anemia and/or thrombocytopenia as a result of progressive marrow failure, AIHA and/or thrombocytopenia poorly responsive to corticosteroids, progressive organomegaly) or progressive lymphocytosis (increase >50% in 2 months or a doubling time of <6 months): Initiate treatment.

- Low-risk disease, Rai stage 0, and Binet stage A: observation with periodic follow-up
- Intermediate-risk group, Rai stages I and II, and Binet stage B: Observe until evidence of disease progression or development of symptoms.
- High-risk patients, Rai stage III and IV, and Binet stage C: Initiate treatment.
- Selection of first-line therapy depends on patient functional status (age, performance status, and medical comorbidities), as well as genetic risk stratification of their CLL (see above).

Main groups of chemotherapeutic drugs:
- Bruton tyrosine kinase inhibitor (targeted therapy) ibrutinib
- BCL2 inhibitor (targeted therapy) venetoclax
- Alkylators (chemotherapy): cyclophosphamide (C), chlorambucil, and bendamustine
- Purine analogs (chemotherapy): fludarabine (F) and pentostatin
- Monoclonal antibodies (immunotherapy): rituximab (R) (chimeric anti-CD20), obinutuzumab (anti-CD20), ofatumumab (anti-CD20)

Commonly used single-agent regimens: bendamustine, cyclophosphamide (historically, the standard of care in older patients with comorbidities), and fludarabine

Targeted therapy preferred as initial therapy for very high and high-risk patients.

- Preferred option includes ibrutinib (especially in elderly based on tolerability, high response rate but continuous) (2)[A]. Can be used with rituximab (3)[A] or obinutuzumab (4)[A].
- Venetoclax: used in combination with obinutuzumab (anti-CD20) (preferred fixed duration regimen for patients with comorbidities and ibrutinib ineligible patients on concomitant medications (5)[A].

Commonly used fludarabine- and rituximab-based combination regimens: FC, FR (lower toxicity), FCR (acceptable first-line regimen in younger patients without high risk features such as del17p or TP53 mutation or IGHV-unmutated CLL), and polymerase chain reaction

- Steroids, high dose: useful in autoimmune manifestations of CLL (AIHA, ITP)

Second Line
- Second-line therapy depends on time to progression.
- Early relapse (within one year after chemoimmunotherapy, 2–3 years after FCR), treatment with targeted therapy is favorable.
  - Ibrutinib
  - Idelalisib (PI3Kδ kinase inhibitor): with rituximab improved progression-free survival in patients with comorbidities and relapsed CLL.
  - Duvelisib (PI3Kδ and PI3Kγ kinase inhibitor): approved as single agent for patients with relapsed CLL who have received at least two prior therapies (PCP prophylaxis is recommended)
  - Venetoclax (BCL-2 inhibitor): approved for use in relapsed/refractory CLL and in patients with 17p deletion
  - Obinutuzumab (humanized anti-CD20 monoclonal antibody): with chlorambucil improved progression-free survival in patients with comorbidities and previously untreated CLL.
  - Ofatumumab (anti-CD20 monoclonal antibody)
- Late relapse (greater than one year after chemoimmunotherapy, 2–3 years after FCR), targeted therapy is favored but retreatment with same therapy also reasonable option.
• Acalabrutinib, an irreversible Bruton tyrosine kinase inhibitor that is more selective than Ibrutinib, has shown high response rate in early clinical trials.
• Lenalidomide, a thalidomide derivative, is sometimes first line for elderly patients or second line when combined with rituximab for relapsed/refractory disease.
• Alemtuzumab (anti-CD52) is second line when used for relapsed/refractory disease.
• Allogenic (nonmyeloablative conditioning) and autologous hematopoietic stem cell transplant (hSCT) may be considered in high-risk and younger patients, particularly those with refractory (limited data available as still considered experimental therapy).

ISSUES FOR REFERRAL
• Surgical consultation for splenectomy in patients with progressive splenomegaly +/- refractory cytopenias
• Radiation oncology consultation for large or bulky lymphadenopathy, particularly those causing compressive symptoms

ADDITIONAL THERAPIES
• Patients requiring therapy who are high risk for tumor lysis syndrome should be given allopurinol to prevent uric acid nephropathy.
• Vaccinations (avoid live vaccines):
  – Annual influenza vaccine
  – Pneumococcal vaccine every 5 years

SURGERY/OTHER PROCEDURES
See “Issues for Referral.”

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
No specific criteria but may require inpatient admission for complications of disease (AIHA) or of therapy (febrile neutropenia, tumor lysis syndrome). Venetoclax is associated with tumor lysis syndrome and requires monitoring inpatient when initiating.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Patients with low-risk CLL and/or patients in remission:
• CBC with differential (lymphocytosis), LDH, and β2-microglobulin every 3 to 6 months
• Physical exam (lymphadenopathy, organomegaly)

DIET
• Ensure adequately balanced calorie/vitamin intake.
• Follow weights regularly for unintentional weight loss

PATIENT EDUCATION
Leukemia and Lymphoma Society has educational pamphlets: https://www.lls.org/resource-center/download-or-order-free-publications?language=English&category=Leukemia&sortby=alpha
PROGNOSIS

- Two staging systems are used, but neither is completely satisfactory: Rai system in the United States and Binet system in Europe
- Rai staging system:
  - Stage 0: lymphocytosis only; low risk status
  - Stage I: lymphocytosis and adenopathy; intermediate risk status
  - Stage II: lymphocytosis +/- adenopathy and splenomegaly and/or hepatomegaly; intermediate risk status
  - Stage III: lymphocytosis and anemia (hemoglobin <11 g/dL); high risk status
  - Stage IV: lymphocytosis and thrombocytopenia (platelets <100 × 10^9/L); high risk status
- Binet staging system:
  - Stage A: hemoglobin ≥10 g/dL, platelets ≥100 × 10^9, and <3 lymph node areas involved (Rai stages 0, I, and II); survival >120 months
  - Stage B: hemoglobin and platelet levels as in stage A and ≥3 lymph node areas involved (Rai stages I and II); survival 61 months
  - Stage C: hemoglobin <10 g/dL, platelets <100 × 10^9, and any number of lymph nodes involved (Rai stages III and IV); survival 32 months
- Adverse risk factors:
  - Advanced Rai or Binet stage
  - Peripheral lymphocyte doubling time <12 months
  - Diffuse marrow infiltration
  - Increased number of prolymphocytes or cleaved cells
  - Poor response to chemotherapy
  - High β₂-microglobulin and thymidine kinase levels and low micro RNAs (miRNAs)
  - Abnormal karyotyping: del(17p) and del(11q)
  - Mutated immunoglobulin heavy chain variable (IgHV) genes (expression of ZAP-70 >20% or CD38 >30% evaluated by immunophenotyping are surrogate markers.)
  - NOTCH1 mutation (associated with unmutated IgVH)

COMPLICATIONS

- Acute or long-term effects of chemotherapy
- Richter syndrome
- AIHA (some cases may be related to the use of fludarabine)
- Slightly increased risk of solid tumors (especially Kaposi sarcoma, malignant melanoma, laryngeal cancer, lung cancer, colon cancer)
- Infection
- Membranoproliferative glomerulonephritis (MPGN) or other glomerular pathology

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- C91.12 Chronic lymphocytic leukemia of B-cell type in relapse
- C91.11 Chronic lymphocytic leukemia of B-cell type in remission
- C91.10 Chronic lymphocytic leukemia of B-cell type not having achieved remission

CLINICAL PEARLS

- CLL is the most common form of leukemia in adults in the United States.
- CLL primarily affects elderly individuals, median age of diagnosis being 70 years. Incidence continues to rise in those age >55 years.
- Clinical monitoring of asymptomatic and low-risk patients is a reasonable approach (“watch and wait”).
- High-risk patients, patients with bulky disease, and patients who fail fludarabine- and rituximab-based therapies typically have poor prognoses and may require intensive therapies, including allogeneic hematopoietic stem cell transplantation.
- Several novel agents are being developed to improve therapeutic approaches to CLL.
LEUKEMIA, CHRONIC MYELOGENOUS
Jan Cerny, MD, PhD • Andrew Gillis-Smith, MD

BASICS

DESCRIPTION
- Chronic myelogenous leukemia (CML) is a myeloproliferative neoplasm characterized by clonal proliferation of myeloid precursors in the bone marrow with continuing differentiation into mature granulocytes.
- Hallmark of CML is Philadelphia chromosome (translocation t[9;22]).
- Natural history of the disease evolves in three clinical phases: a chronic phase, an accelerated phase, and a blast phase or crisis (transformation to acute leukemia).

EPIDEMIOLOGY

Incidence
- Per year, 1.9 cases/100,000 persons
- Median age at diagnosis: 65 years
- Predominant sex: male > female (1.7:1)

Prevalence
Accounts for 15–20% of adult leukemias

ETIOLOGY AND PATHOPHYSIOLOGY
Philadelphia chromosome is a balanced translocation between BCR (on chromosome 22) and ABL (on chromosome 9) genes t(9;22)(q34;q11). This fusion gene, BCR-ABL, codes for an abnormal, constitutively active tyrosine kinase that affects numerous signal transduction pathways, resulting in uncontrolled cell proliferation and reduced apoptosis.

Genetics
Acquired genomic changes

RISK FACTORS
Ionizing radiation exposure (uncommon)

GENERAL PREVENTION
None currently identified

DIAGNOSIS

85–90% of patients present in the chronic phase, and the disease can be found incidentally during routine screening.

HISTORY
- Chronic phase: fatigue, weight loss, night sweats, abdominal fullness owing to enlarged spleen, early satiety, dyspnea, and bleeding. Rare: bruising, left upper quadrant abdominal pain, sternal pain (owing to expanding bone marrow), and gouty arthritis; up to 30% of patients are
asymptomatic.

- Accelerated phase: progressive splenomegaly and left upper quadrant abdominal pain occasionally referred to the left shoulder (owing to splenic infarction or rupture), progressive weight loss and sweats, unexplained fever or bone pain, chloromas (extramedullary tumors)
- Blast phase: bleeding, bruising, infections, prominent constitutional symptoms

PHYSICAL EXAM
- Splenomegaly (50–90%), hepatomegaly (up to 50%)
- Less common: splenic friction rub, lymphadenopathy

DIFFERENTIAL DIAGNOSIS
- Chronic myelomonocytic leukemia, chronic neutrophilic leukemia, chronic eosinophilic leukemia, juvenile myelomonocytic leukemia, infectious mononucleosis, leukemoid reaction, polycythemia vera, and treatment with granulocyte-stimulating factors
- Acute myelogenous leukemia resembles blast crisis with myeloid blasts, and acute lymphoblastic leukemia resembles blast crisis with lymphoid blasts.
- Atypical CML is a chronic myeloproliferative disorder with a clinical hematologic picture similar to CML, but it lacks the Philadelphia chromosome and BCR-ABL rearrangement.

DIAGNOSTIC TESTS & INTERPRETATION
- Complete blood count (CBC)
  - White blood cell (WBC) count: markedly increased (50,000 to 100,000/μL), with granulocytes in all stages of maturation, including occasional (<10%) blasts in chronic phase, basophilia, eosinophilia
  - Hematocrit: may be normal, slightly increased, or decreased
  - Platelets: may be normal, elevated, or occasionally low
  - In accelerated phase: anemia, >20% basophils, thrombocytopenia
- Bone marrow biopsy: Hypercellular marrow, myeloid hyperplasia. In accelerated phase: 10–19% blasts, >20% blasts in blood or marrow indicates blast phase
- Genetics
  - Demonstration of the Philadelphia chromosome, t(9;22), by cytogenetic techniques, fluorescence in situ hybridization (FISH), or reverse transcription-polymerase chain reaction (RT-PCR)
  - Additional cytogenetic abnormalities occur in the accelerated and blast phases (monosomy 7; t[3,21]; trisomies 8 and 19; Philadelphia chromosome duplication; abnormalities of chromosome 17 such as monosomy, trisomy, and isochromosome mutations). These may contribute to resistance to tyrosine kinase inhibitors (TKIs; e.g., imatinib). Further molecular testing (mutations within BCR-ABL) is suggested in case of loss of response to therapy.
- Others:
  - Low or absent leukocyte alkaline phosphatase in neutrophils
  - High lactate dehydrogenase (LDH)
  - Elevated uric acid

Initial Tests (lab, imaging)
- CBC, LDH, uric acid, bone marrow biopsy and aspiration, cytogenetics on bone marrow, and FISH for BCR-ABL, RT-PCR, liver function tests
- Abdominal ultrasound or CT scan shows splenomegaly; not mandatory
Follow-Up Tests & Special Considerations
- Serial monitoring of BCR-ABL by RT-PCR is used to evaluate response to treatment
- Mutation analysis of tyrosine kinase domain of ABL kinase can predict resistance to therapy with TKIs
- HLA-A*02 positive is associated with CML, and a protective effect is seen with the HLA-B*35 allele (pooled odds ratio 0.64, 95% CI 0.48–0.86).

Diagnostic Procedures/Other
Bone marrow aspiration and biopsy

Test Interpretation
Myeloid hyperplasia with elevated myeloid: erythroid ratio, normal maturation, marrow basophilia, and increased reticulin fibrosis

TREATMENT

MEDICATION
- TKIs (e.g., imatinib) provide durable, long-term control of disease.
- The response to TKIs is assessed at specific time points from the beginning of treatment and is categorized as follows:
  - Complete hematologic response (CHR): normalization of peripheral counts, no disease symptoms, no immature cells
  - Complete cytogenetic response (CCR): no Philadelphia-positive metaphases on chromosome analysis
  - Major molecular response (MMR): decreased level of BCR-ABL transcript by PCR 3-log
  - Complete molecular response (CMR): BCR-ABL transcript is undetectable by PCR.

First Line
- Imatinib mesylate (Gleevec), an oral TKI, 400 mg/day
- Side effects: thrombocytopenia, anemia, elevated liver enzymes, edema, GI disturbances, rash
- International Randomized Study of Interferon versus STI571 (IRIS) established imatinib as first-line therapy (1)[A].
- Imatinib dose can be increased to 600 and 800 mg/day if only suboptimal response is achieved with standard dose.
- 2nd-generation TKIs have shown higher efficacy and fewer side effects and are approved for first-line therapy of chronic phase CML: nilotinib (Tasigna), dasatinib (Sprycel), and bosutinib (Bosulif) (2,3,4)[A].

Second Line
- 2nd-generation TKIs; active against most of BCR-ABL mutants; not active in T315I mutation
  - Dasatinib
    - 100 mg/day in patients resistant or intolerant to imatinib and 70 mg BID or 140 mg/day for patients in accelerated or blastic phase
    - Side effects: pleural effusions, cytopenias
  - Nilotinib
    - 400 mg PO BID in patients resistant or intolerant to imatinib in chronic or accelerated phase
Side effects: cytopenias, QTc prolongation, pancreatitis

- Bosutinib
  - 400 mg PO daily, 500 mg in patients resistant or intolerant to prior therapy in chronic or accelerated phase
- Side effects: GI toxicity, myelosuppression, hepatotoxicity, fluid retention
- Omacetaxine is approved for patient with resistance or intolerance to two TKIs.
- Ponatinib has restricted approval due to the risk of thrombotic events, but together with omacetaxine, they are the only effective agents in patients with T315I mutation. Agents targeting leukemic stem cells are being developed for clinical use.

ISSUES FOR REFERRAL
All patients with CML should be referred to a hematologist. Patients with inadequate response to TKIs or with T315I mutation should consult with a bone marrow transplant (BMT) physician.

SURGERY/OTHER PROCEDURES
Allogeneic BMT
- It is the only known cure; however, 71% of patients who achieve CCR with imatinib maintain that response beyond 7 years, and no patient progressed on the trial between years 5 and 6 of treatment.
- Most effective in patients <50 years of age who are in the chronic phase
- Initial mortality is higher (related to the use of myeloablative regimens) than medical management but provided higher rates of survival in pre-TKI era.
- Significant improvement in transplant techniques leading to better outcomes, such as alternative sources of stem cells; nonmyeloablative regimens have shown improvements in transplant-related mortality.
- Transplant option should be thoroughly discussed with young patients in chronic phase and considered an alternative to TKIs, especially if the patient does not tolerate TKIs or disease is not responding.
- Can be considered in patients who fail to achieve CHR by 3 months, have no cytogenetic response or cytogenetic relapse, or have T315I mutation

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Acute abdominal symptoms (infarcted or ruptured spleen); tumor lysis syndrome owing to initial therapy; complications of BMT
  - Hydroxyurea might be given, with the goal of reduction of the WBC count, but it has minimal impact on patient response to TKIs.
  - Induction chemotherapy (for acute leukemia) in setting of blastic phase
  - Allopurinol to prevent tumor lysis syndrome in patients with very high counts; however, probably not necessary when TKIs are used
- Discharge criteria: abatement of acute symptoms

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Frequency depends on stage at presentation and response to first-line therapy.
- Although splenomegaly persists, avoid contact sports or trauma to abdomen.
**Patient Monitoring**
- CBC with differential: weekly until blood counts stable and then every 2 to 4 weeks during CHR; once in CCR and stable, patient can be followed less frequently (3-month intervals).
- Bone marrow cytogenetics (evaluation for clonal evolution) every 6 months while in CHR, every 12 to 18 months while in CCR, MMR, CMR
- Quantitative RT-PCR every 3 months (peripheral blood)
- Electrocardiograms (concern for QT prolongation), LFTs while on TKIs. Nilotinib, bosutinib, and ponatinib can cause pancreatitis.
- Blood pressure monitoring because several TKIs have been associated with elevated blood pressure and related cardiovascular complications

**PROGNOSIS**
- With treatment and good response, the survival is similar to the normal population.
- Without treatment: CML invariably will progress to accelerated phase within 2 to 5 years and blast phase within several months of the accelerated phase.
- Poor prognosis: patients presenting in accelerated or blastic phase or presenting with very large spleen size, platelets >700,000/μL, and patients resistant to TKIs (T315I mutation)

**COMPLICATIONS**
- Splenic infarct or rupture
- Progression to accelerated or blastic phase
- Thrombotic events owing to elevated platelets
- Bleeding owing to low or dysfunctional platelets
- Sequelae of anemia

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- C92.2 Atypical chronic myeloid leukemia, BCR/ABL-negative
- C92.12 Chronic myeloid leukemia, BCR/ABL-positive, in relapse
- C92.22 Atypical chronic myeloid leukemia, BCR/ABL-negative, in relapse

**CLINICAL PEARLS**
- CML belongs to the myeloproliferative disorders group.
- The gold standard for diagnosis of CML is detection of the Philadelphia chromosome or its products, BCR-ABL mRNA, and fusion protein.
- TKIs provide durable, long-term control of the disease and have dramatically altered treatment.
- Atypical CML is a form of clinically typical CML but without the presence of the typical BCR-ABL translocation.
- Blast crisis is a form of acute leukemia that is a possible complication of CML.
LEUKOPLAKIA, ORAL
Kathya M. Chartre, MD

BASICS

DESCRIPTION
- Oral leukoplakia refers to white plaque or patches on the oral mucosa, that can undergo a malignant transformation over time.
- System(s) affected: gastrointestinal
- Hyperplasia of squamous epithelium

EPIDEMIOLOGY
- Increases with age but mostly develops in middle age
- Most common where more people smoke and chew tobacco and areca nuts (Asian populations).

Prevalence
- 1–3% of the worldwide population is affected (1).
- Age of onset is >40 years old with peak in the 60s (1).
- Males 3 times more likely to be affected as females (1)
- Smokers 6 times more likely to be affected than nonsmokers (1)

Geriatric Considerations
Malignant transformation to carcinoma is more common in older patients.

ETIOLOGY AND PATHOPHYSIOLOGY
Hyperkeratosis or dyskeratosis of the oral squamous epithelium
- Tobacco use in any form
- Alcohol consumption/alcoholism
- Periodontitis
- Candida albicans infection may induce dysplasia and increase malignant transformation.
- Human papillomavirus, types 16 and 18
- Sunlight
- Vitamin deficiency
- Syphilis
- Dental restorations/prosthetic appliances
- Estrogen therapy
- Chronic trauma or irritation
- Epstein-Barr virus (oral hairy leukoplakia)
- Areca nut/betel (Asian populations)
- Mouthwash preparations and toothpaste containing the herbal root extract sanguinaria

Genetics
- Dyskeratosis congenital and epidermolysis bullosa increase the likelihood of oral malignancy.
- P53 overexpression, PTEN allelic loss correlates with leukoplakia and particularly squamous cell carcinoma.
Biomarkers: IL-6, -8 and TNF-α have been detected in leukoplakia and there is new research showing elevated levels of Hsp27

RISK FACTORS
- 70–90% of oral leukoplakia is related to tobacco, particularly smokeless tobacco or areca/betel nut use.
- Similar to risk factors for squamous cell carcinoma
- Alcohol increases risk 1.5-fold.
- Repeated or chronic mechanical trauma from dental appliances or cheek biting
- Chemical irritation to oral regions
- Diabetes
- Age
- Socioeconomic status
- Risk factors for malignant transformation of leukoplakia
  - Female
  - Long duration of leukoplakia
  - Nonsmoker (idiopathic leukoplakia)
  - Located on tongue or floor of mouth
  - Size >200 mm²
  - Nonhomogeneous type
  - Presence of epithelial dysplasia

GENERAL PREVENTION
- Avoid tobacco of any kind, alcohol, habitual cheek biting, tongue chewing
- Use well-fitting dental equipment.
- Regular dental check-ups to avoid bad restorations
- Diet rich in fresh fruits and vegetables may help to prevent cancer.
- Human papillomavirus vaccination may be preventive.

COMMONLY ASSOCIATED CONDITIONS
- HIV infection is closely associated with hairy leukoplakia.
- Erythroplakia in association with leukoplakia, “speckled leukoplakia,” or erythroleukoplakia is a marker for underlying dysplasia.
- 1–20% of lesions will progress to carcinoma within 10 years.

DIAGNOSIS
Leukoplakia is an asymptomatic white patch on the oral mucosa.

HISTORY
- Usually asymptomatic
- History of tobacco or alcohol use or oral exposure to irritants

PHYSICAL EXAM
- Location
  - 50% on tongue, mandibular alveolar ridge, and buccal mucosa
  - Also seen on maxillary alveolar ridge, palate, and lower lip
– Infrequently seen on floor of the mouth and retromolar areas
– Floor of mouth, ventrolateral tongue, and soft palate complex are more likely to have dysplastic lesions.

● Appearance
– Varies from homogeneous, nonpalpable, faintly translucent white areas to thick, fissured, papillomatous, indurated plaques
– May feel rough or leathery
– Lesions can become exophytic or verruciform.
– Color may be white, gray, yellowish white, or brownish gray.
– Cannot be wiped or scraped off

● World Health Organization classification
– Homogeneous refers to color.
  o Flat, corrugated, wrinkled, or pumice
– Nonhomogeneous refers to color and texture (more likely to be dysplastic or malignant).
  o Erythroleukoplakia (mixture of red and white)
  o Proliferative verrucous leukoplakia (PVL) (multifocal, mostly women)

DIFFERENTIAL DIAGNOSIS
● White oral lesions that can be rubbed off: acute pseudomembranous candidiasis
● White oral lesions that cannot be rubbed off (2):
  – Developmental/genetic (rare):
    o Cannon white sponge nevus (diffuse bilateral white plaques of buccal mucosa, tongue)
    o Hereditary benign intraepithelial dyskeratosis
    o Pachyonychia congenita
  – Reactive/frictional:
    o Leukoedema (delicate gray-white lines, disappear with stretching)
    o Contact desquamation
    o Morsicatio mucosae oris (cheek/gum biting)
    o Benign alveolar ridge keratosis (ill-fitting dentures)
    o Hairy tongue (elongated filiform papillae, may become pigmented from food/bacteria)
    o Nicotinic stomatitis and smokeless tobacco keratosis (South Asian “paan” or “gutka”; American/Swedish snuff; Ethiopian “toombak”)
  – Infectious:
    o Candidiasis
    o Hairy leukoplakia (associated with Epstein-Barr virus and HIV-infected individuals)
  – Immune-mediated:
    o Lichen planus (typically symmetric, bilateral, reticular white lesions)
    o Lichenoid lesions
    o Benign migratory glossitis
  – Autoimmune:
    o Systemic lupus erythematosus
    o Chronic graft versus host disease

DIAGNOSTIC TESTS & INTERPRETATION
Biopsy with histopathologic examination is the gold standard.

Initial Tests (lab, imaging)
Laboratory tests generally are not indicated.
- Consider saliva culture if *C. albicans* infection is suspected.
- No imaging is indicated.

**Follow-Up Tests & Special Considerations**
- Biopsy is necessary to rule out carcinoma if lesion is persistent, changing, or unexplained.
- Consider complete blood count, rapid plasma reagin (RPR).

**Diagnostic Procedures/Other**
- Oral cytology is superior to conventional oral examination (3)[A].
- Computer-assisted cytology or liquid-based cytology is not superior to oral cytology (3)[A].
- Noninvasive brush biopsy and analysis of cells with DNA—image cytometry constitute a sensitive and specific screening method.
- Patients with dysplastic or malignant cells on brush biopsy should undergo more formal excisional biopsy.
- Excisional biopsy is definitive procedure.

**Test Interpretation**
- Biopsy specimens range from hyperkeratosis to keratosis of unknown significance (KUS) to dysplasia to invasive carcinoma.
- At initial biopsy, 6% are invasive carcinoma.
- 0.13–6% subsequently undergo malignant transformation.
- Location is important: 60% on floor of mouth or lateral border of tongue are cancerous; buccal mucosal lesions are generally not malignant but require biopsy if not resolving.

**TREATMENT**
- All oral leukoplakias should be treated because they are potentially malignant.
- Treatment may include the following:
  - For 2 to 3 circumscribed lesions, surgical excision is treatment of choice (4)[C].
  - For multiple or large lesions where surgery would cause unacceptable deformity, consider cryosurgery or laser surgery (4)[C].
  - Abstinence from predisposing habits (alcohol and tobacco)
- Complete excision is standard treatment for dysplasia or malignancy.
- After treatment, up to 30% of leukoplakia recurs, and some leukoplakia still transforms to squamous cell carcinoma (4)[B].
- Oral hairy leukoplakia may be treated with podophyllin with acyclovir cream.

**GENERAL MEASURES**
- Eliminate habitual lip biting.
- Correct ill-fitting dental appliances, bad restorations, or sharp teeth.
- Stop smoking and using alcohol.
- Some small lesions may respond to cryosurgery.
- \(\beta\)-Carotene, lycopene, retinoids, and cyclooxygenase-2 (COX-2) inhibitors may cause partial regression.
- For hairy tongue: tongue brushing
MEDICATION
Carotenoids; vitamins A, C, and K; bleomycin; and photodynamic therapy ineffective to prevent malignant transformation and recurrence

ISSUES FOR REFERRAL
Consider otolaryngologist or oral surgery referral for extensive disease.

SURGERY/OTHER PROCEDURES
- Scalpel excision, laser ablation, electocautery, or cryoablation
- Cryotherapy slightly less effective than photodynamic therapy response (73% vs. 90%) and recurrence (27% vs. 24%) (5)[A]
- CO$_2$ laser had 20% recurrence and 10% malignant transformation within 5 years (6)[B].
- Biopsy/excision algorithm (2)[C]:
  - KUS that is poorly demarcated and likely frictional: Rebiopsy and follow up.
  - KUS that is well demarcated and >3 cm: Follow up every 3 months; rebiopsy every 12 months.
  - KUS that is <3 cm: Excise/ablate with narrow margins; follow up every 3 months; if recurs, excise with wider margins.
  - PVL: Follow up every 3 months; excise verrucous or nodular areas.
  - Dysplastic/SCC: Excise.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Eliminate etiologic factors.
- Reevaluate in 7 to 14 days.
- Biopsy if lesion is persistent

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Regular, close follow-up, even after successful treatment
- Biopsy as needed

DIET
Regular

PATIENT EDUCATION
- If biopsy is negative, stress importance of periodic and careful follow-up.
- Initiate a dental referral to eliminate dental factors.
- Stress importance of stopping tobacco and alcohol use.
- Encourage participation in smoking cessation program.

PROGNOSIS
- Most leukoplakia is benign.
- Leukoplakia may regress, remain stable, or progress.
- 0.13–6% of initially benign lesions subsequently develop into cancer.
- Size >4 cm increases risk of malignant transformation.
- 5-year survival rate of oral cancer is 50%.

**COMPLICATIONS**
- New lesions may develop after treatment.
- Risk of malignant transformation to squamous cell carcinoma is approximately 5–17%.
- Larger lesions and nonhomogeneous leukoplakia are associated with higher rates of malignant transformation.

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**
HIV/AIDS; Infectious Mononucleosis, Epstein-Barr Virus Infections

**CODES**

**ICD10**
- K13.21 Leukoplakia of oral mucosa, including tongue
- K13.3 Hairy leukoplakia

**CLINICAL PEARLS**
- White plaque or patches on the oral mucosa that cannot be rubbed or easily scrapped off
- Excisional biopsy is indicated for any undiagnosed leukoplakia.
- After treatment, up to 30% of leukoplakia recurs, and some leukoplakia still transforms to
squamous cell carcinoma; thus, long-term surveillance is essential.

- To lessen risk of malignant transformation, encourage tobacco and alcohol cessation and consider C. albicans eradication.
LICHEN PLANUS
Mercedes E. Gonzalez, MD • Herbert P. Goodheart, MD

BASICS
Lichen planus (LP) is an idiopathic eruption with characteristic shiny, flat-topped (Latin: planus, “flat”) purple (violaceous) papules and plaques on the skin, often accompanied by characteristic mucous membrane lesions. Itching may be severe.

DESCRIPTION
• Classic (typical) LP is a relatively uncommon inflammatory disorder of the skin and mucous membranes; hair and nails may also be affected.
  – Skin lesions are small, flat, angular, red-to-violaceous, shiny, pruritic papules and/or plaques with overlying fine, white lines (called Wickham striae), or gray-white puncta; most commonly seen on the flexor surfaces of the upper extremities, extensor surfaces of the lower extremities, the genitalia, and on the mucous membranes
  – On the oral mucosa, lesions typically appear as raised white lines in a lacelike pattern seen most often on the buccal mucosa.
  – Onset is abrupt or gradual. Course is unpredictable; may resolve spontaneously, recur intermittently, or persist for many years
• Drug-induced LP
  – Clinical and histopathologic findings may mimic those of classic LP. Lesions usually lack Wickham striae (see in the following text) and oral involvement is rare.
  – There is generally a latent period of months from drug introduction until lesions appear.
  – Lesions resolve when the inciting agent is discontinued, often after a prolonged period.
• LP variants
  – Follicular: also called lichen planopilaris; typically seen on the scalp, can lead to scarring alopecia
  – Annular: Papules spread centrifugally as central area resolves; occur on glans penis, axillae, and oral mucosa
  – Linear: may be an isolated finding
  – Hypertrophic: itchy, hyperkeratotic, thick plaques on dorsal legs and feet
  – Atrophic: rare, most often the result of resolved lesions
  – Bullous LP: Intense inflammation in the dermis leads to blistering of epidermis.
  – LP pemphigoides: a combination of LP and bullous pemphigoid (IgG autoantibodies to collagen 17)
  – Nail LP: affects the nail matrix, lateral thinning, longitudinal ridging, and fissuring
• System(s) affected: skin/exocrine
• Synonym(s): lichenoid eruptions

EPIDEMIOLOGY
• Predominant age: 30 to 60 years old; rare in children and the geriatric population
• Predominant sex: female > male

Prevalence
In the United States, 450/100,000
ETIOLOGY AND PATHOPHYSIOLOGY
LP is considered to be a T cell–mediated autoimmune response to self-antigens on damaged keratinocytes.

RISK FACTORS
Exposure to certain drugs or chemicals
- Thiazides, furosemide, β-blockers, sulfonylureas, antimalarials, penicillamine, gold salts, and angiotensin-converting enzyme inhibitors
- Rarely: photo-developing chemicals, dental materials, tattoo pigments

COMMONLY ASSOCIATED CONDITIONS
- An association has been noted between LP and hepatitis C virus infection, particularly in certain geographic regions (Asia, South America, the Middle East, Europe) (1). Hepatitis should be considered in patients with widespread presentations of LP and those with primarily oral disease.
- In addition, chronic active hepatitis, lichen nitidus, and primary biliary cirrhosis have been noted to coexist with LP.
- Association with dyslipidemia has been reported (2) [B].
- LP has also been reported in association with other diseases of altered immunity, more often than would be expected by chance.
  - Bullous pemphigoid
  - Alopecia areata
  - Myasthenia gravis
  - Vitiligo
  - Ulcerative colitis
  - Graft-versus-host reaction
  - Lupus erythematosus (lupus erythematosus–LP overlap syndrome)
  - Morphea and lichen sclerosis et atrophicus

DIAGNOSIS
LP is most commonly diagnosed by its appearance despite its range of clinical presentations. A skin biopsy should be performed if the diagnosis is in doubt.

HISTORY
A minority of patients have a family history of LP. Affected families have an increased frequency of human leukocyte antigen B7 (HLA-B7). A thorough drug history should be performed.

PHYSICAL EXAM
- Skin (often severe pruritus)
  - Papules: 1 to 10 mm, shiny, flat-topped (planar) lesions that occur in crops; lesions may have a fine scale.
  - Evidence of scratching (i.e., crusts and excoriations) is usually absent.
  - Color: violaceous, with white lacelike pattern (Wickham striae) on surface of papules. Wickham striae are best seen after topical application of mineral oil and, if present, are virtually pathognomonic for LP.
– Shape: polygonal or oval. Annular lesions may appear on trunk and mucous membranes. Various shapes and sizes may be noted (polymorphic).
– Arrangement: may be grouped, linear, or scattered individual lesions
– Koebner phenomenon (isomorphic response): New lesions may be noted at sites of minor injuries, such as scratches or burns.
– Distribution: ventral surface of wrists and forearms, dorsa hands, glans penis, dorsa feet, groin, sacrum, shins, and scalp. Hypertrophic ( verrucous) lesions may occur on lower legs and may be generalized.
– Postinflammatory hyperpigmentation: Lesions typically heal, leaving darkly pigmented macules in their wake.

Mucous membranes (40–60% of patients with skin lesions; 20% have mucous membrane lesions without skin involvement.)
– Most commonly asymptomatic, nonerosive, milky-white lines with an elegant, lacy, netlike streaked pattern
– Usually seen on buccal mucosa but may appear on tongue, gingiva, palate, or lips
– Less commonly, LP may be erosive; rarely bullous
– Painful, especially if ulcers present
– Lesions may develop into squamous cell carcinoma (1–3%).
– Glans penis, labia minora, vaginal vault, and perianal areas may be involved.

Hair/scalp
– LP of the hair follicle (lichen planopilaris) presents with keratotic plugs at the follicle orifice with a violaceous rim; may result in atrophy and permanent destruction of hair follicles (scarring alopecia)

Nails (10%)
– Involvement of nail matrix may cause proximal-to-distal linear grooves and partial or complete destruction of nail bed with pterygium formation.

DIFFERENTIAL DIAGNOSIS

Skin
– Lichen simplex chronicus
– Eczematous dermatitis
– Psoriasis
– Discoid lupus erythematosus
– Other lichenoid eruptions (those that resemble LP)
– Pityriasis rosea
– Lichen nitidus

Oral mucous membranes
– Leukoplakia
– Oral hairy leukoplakia
– Candidiasis
– Squamous cell carcinoma (particularly in ulcerative lesions)
– Aphthous ulcers
– Herpetic stomatitis
– Secondary syphilis

Genital mucous membranes
– Psoriasis (penis and labia)
– Nonspecific balanitis, Zoon balanitis
- Fixed drug eruption (penis)
- Candidiasis (penis and labia)
- Pemphigus vulgaris, bullous pemphigoid, and Behçet disease (all rare)

**Hair and scalp**
- Scarring alopecia (central centrifugal cicatricial alopecia)

**DIAGNOSTIC TESTS & INTERPRETATION**

*If suggested by history*
- Serology for hepatitis
- Liver function tests

**Diagnostic Procedures/Other**
- Skin biopsy
- Direct immunofluorescence helps to distinguish LP from discoid lupus erythematosus.

**Test Interpretation**
- Dense, bandlike (lichenoid) lymphocytic infiltrate of the upper dermis
- Vacuolar degeneration of the basal layer
- Hyperkeratosis and irregular acanthosis, increased granular layer
- Basement membrane thinning with “saw-toothing”
- Degenerative keratinocytes, known as colloid or Civatte bodies, are found in the lower epidermis.
- Melanin pigment in macrophages

**TREATMENT**

Although LP can resolve spontaneously, treatment is usually requested by patients who may be severely symptomatic or troubled by its cosmetic appearance.

**GENERAL MEASURES**
- Goal is to relieve itching and resolve lesions.
- Asymptomatic oral lesions require no treatment.

**MEDICATION**

**First Line**
- Skin
- Superpotent topical steroids (e.g., 0.05% clobetasol propionate) twice daily
  - Potent topical steroids such as triamcinolone acetonide 0.1% or fluocinonide 0.05% under occlusion
  - Intraleisional corticosteroids (e.g., triamcinolone [Kenalog] 5 to 10 mg/mL) for recalcitrant and hypertrophic lesions
  - Antihistamines (e.g., hydroxyzine 25 mg PO q6h) have limited benefit for itching but may be helpful for sedation at bedtime.
  - “Soak and smear” technique: can lead to a rapid improvement of symptoms in even 1 to 2 days and may obviate the need for systemic steroids. Soaking allows water to hydrate the stratum corneum and allows the anti-inflammatory steroid in the ointment to penetrate more deeply into the skin. Smearing of the ointment traps the water in the skin because water
cannot move out through greasy materials.
- Soaking is done in a bathtub using lukewarm plain water for 20 minutes and then, without drying the skin, the affected area is immediately smeared with a thin film of the steroid ointment containing clobetasol or another superpotent topical steroid.
- Soak and smear may be done for 4 to 5 days or longer, if necessary. The treatments are best done at night because the greasy ointment applied to the skin gets on pajamas (instead of on daytime clothes) and the ointment is on the skin during sleep. A topical steroid cream is applied thereafter during the daytime hours, if necessary.

- **Mucous membranes**
  - For oral, erosive, painful LP, a Cochrane review found, at best, weak evidence for the effectiveness of any intervention (3)[A].
    - Topical corticosteroids (0.1% triamcinolone [Kenalog] in Orabase) or 0.05% clobetasol propionate ointment BID
    - Intraleral corticosteroids
    - Topical 0.1% tacrolimus (Protopic ointment) BID or 1% pimecrolimus (Elidel) cream BID. A Cochrane review found no evidence that calcineurin inhibitors are better than placebo (4)[A].
    - Topical retinoids (e.g., 0.05% tretinoin [retinoic acid] in Orabase)

**Pediatric Considerations**
Children may absorb a proportionally larger amount of topical steroid because of larger skin surface-to-weight ratio.

**Second Line**
Skin and mucous membranes
- Intraleral corticosteroids
- Topical 0.1% tacrolimus (Protopic ointment) BID or topical 1% pimecrolimus (Elidel) cream BID
- Oral prednisone: used only for a short course (e.g., 30 to 60 mg/day for 2 to 4 weeks) or IM triamcinolone (Kenalog) 40 to 80 mg every 6 to 8 weeks
  - Precautions with systemic steroids
    - Systemic absorption of steroids may result in hypothalamic-pituitary-adrenal axis suppression, Cushing syndrome, hyperglycemia, or glucosuria.
    - Increased risk with high-potency topical steroids (i.e., use over large surface area, prolonged use, occlusive dressings)
    - In pregnancy: usually safe, but benefits must outweigh the risks
- Oral retinoids: Isotretinoin in doses of 10 mg PO daily for 2 months, acitretin 30 mg, or alitretinoin 30 mg PO daily have resulted in improvement in some refractory cases. Observe carefully for resultant dyslipidemia.
- Oral metronidazole 500 mg BID for 20 to 60 days can be given as a safer alternative to systemic corticosteroids.
- Cyclosporine may be used in severe cases, but cost and potential toxicity limit its use; topical use for severe oral involvement refractory to other treatments
- Thalidomide
- Psoralen ultraviolet-A (PUVA), broad- or narrow-band ultraviolet B (UVB) (5)[A]
- Low-level laser therapy and photodynamic therapy
- Griseofulvin (5)[A]
Azathioprine
Mycophenolate mofetil
Metronidazole

**ALERT**
Avoid oral and topical retinoids during pregnancy.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Outpatient care

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Serial oral examinations for erosive/ulcerative lesions

**PATIENT EDUCATION**
- Oral, erosive, or ulcerative LP: annual follow-up to screen for malignancy (6)[A]
- Avoid spicy foods, cigarettes, and excessive alcohol.
- Avoid dry, crispy foods such as corn chips, pretzels, and toast.

**PROGNOSIS**
- Spontaneous resolution in weeks is possible, but disease may persist for years, especially oral lesions and hypertrophic lesions on the shins.
- There is a tendency toward relapse.
- Recurrence in 12–20%, especially in those with generalized involvement

**COMPLICATIONS**
- Alopecia
- Nail destruction
- Squamous cell carcinoma of the mouth or genitals

CODES

ICD10

- L43.9 Lichen planus, unspecified
- L43.0 Hypertrophic lichen planus
- L43.1 Bullous lichen planus

CLINICAL PEARLS

- Remember the 7 P’s of LP: purple, planar, polygonal, polymorphic, pruritic (not always), papules that heal with postinflammatory hyperpigmentation
- Serial oral or genital exams are indicated for erosive/ulcerative LP lesions to monitor for the development of squamous cell carcinoma.
- An association has been noted between LP and hepatitis C virus infection, chronic active hepatitis, and primary biliary cirrhosis.
- The “soak and smear” technique can lead to a rapid improvement of symptoms in 1 to 2 days and may obviate the need for systemic steroids.
**BASICS**

**DESCRIPTION**
- Lichen simplex chronicus (LSC) is a chronic dermatitis resulting from chronic, repeated rubbing or scratching of the skin. Skin becomes thickened with accentuated lines ("lichenification").
- System(s) affected: skin
- Synonym(s): LSC; lichen simplex; localized neurodermatitis; neurodermatitis circumsipta

**EPIDEMIOLOGY**

**Geriatric Considerations**
Most common in middle aged and elderly

**Pediatric Considerations**
Rare in preadolescents

**Incidence**
- Common
- Peak incidence 35 to 50 years
- Predominant sex: females > males (2:1)

**Prevalence**
Common

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Itch–scratch cycle leads to a chronic dermatosis. Repeated scratching or rubbing causes inflammation and pruritus, which leads to continued scratching.
- Primary LSC: scratching secondary to nonorganic pruritus, habit or a conditioned response to stress/anxiety
- Common triggers are excess dryness of skin, heat, sweat, and psychological stress.
- Secondary LSC: begins as a pruritic skin disease that evolves into neurodermatitis, which persists after resolution of the primary condition. Precursor dermatoses include atopic dermatitis, contact dermatitis, lichen planus, stasis dermatitis, psoriasis, tinea, and insect bites.
- There is a possible relation between disease development and underlying neuropathy, particularly radiculopathy or nerve root compression.
- Pruritus-specific C neurons are temperature sensitive, which may explain itching that occurs in warm environments.

**RISK FACTORS**
- Anxiety disorders
- Dry skin
- Insect bites
- Pruritic dermatosis
GENERAL PREVENTION
Avoid common triggers such as psychological distress, environmental factors such as heat and excessive dryness, skin irritation, and the development of pruritic dermatoses.

COMMONLY ASSOCIATED CONDITIONS
- Prurigo nodularis is a nodular variety of the same disease process.
- Atopic dermatitis
- Anxiety, depression, and obsessive-compulsive disorders

DIAGNOSIS

HISTORY
- Gradual onset
- Begins as a localized area of pruritus
- Most patients acknowledge that they respond with vigorous rubbing, itching, or scratching, which brings temporary satisfaction.
